- 11) Including current transformer, circuit path and X20TB12 terminal block (5 mΩ)

9.26.4.5 Safety guidelines

General information

Programmable logic controllers, operating/monitoring devices (e.g. industrial PCs, Power Panels, Mobile Panels, etc.) as well as uninterruptible power supplies have all been designed, developed and manufactured by B&R for conventional use or for use with increased safety requirements (safety technology) in industry. They were not designed, developed and manufactured for any use involving serious risks or hazards that could lead to death, injury, serious physical damage or loss of any kind without the implementation of exceptionally stringent safety precautions. In particular, such risks and hazards include the use of these devices to monitor nuclear reactions in nuclear power plants, their use in flight control or flight safety systems as well as in the control of mass transportation systems, medical life support systems or weapons systems.

When using programmable logic controllers or operating/monitoring devices as control systems together with a Soft PLC (e.g. B&R Automation Runtime or comparable product) or Slot PLC (e.g. B&R LS251 comparable product), safety precautions relevant to industrial control systems (e.g. the provision of safety devices such as emergency stop circuits, etc.) must be observed in accordance with applicable national and international regulations. The same applies for all other devices connected to the system, e.g. drives.

All tasks such as the installation, commissioning and servicing of devices are only permitted to be carried out by qualified personnel. Qualified personnel are those familiar with the transport, mounting, installation, commissioning and operation of devices who also have the appropriate qualifications (e.g. IEC 60364-1). National accident prevention regulations must be observed.

The safety notices, connection descriptions (type plate and documentation) and limit values listed in the technical data are to be read carefully before installation and commissioning and must be observed.

Intended use

Danger!

Electronic devices are never completely failsafe. If the multi-measurement and synchronization unit fails, the user is responsible for making sure that the motor or generator is brought to a secure state.

Some errors are detected and prevented in the synchronization unit by the system's internal software monitoring. However, when the device is in operation it is always possible for errors, defective components, software errors or configuration mistakes to occur at any time. B&R emphasizes that the multi-measurement and synchronization unit possesses neither a failsafe function nor a redundancy system. For this reason, independent higher-level safety precautions need to be put in place to ensure that personnel and machines are protected.

Grounding the Mounting Rail

For grounding purposes, a good conductive connection between the mounting rail and the metal back wall is required. The mounting rail is to be connected conductively to the back wall. This is achieved by inserting a contact washer with the fastening screw.

Information:

The control cabinet back wall must be connected with GND

9.26.4.6 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

LED status indicators - Right

| Figure | LED | Color | Status | Description |
|--------|-------|-----------------------------|------------------|---|
| | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1 - 6 | Orange | | Output status of the corresponding digital output |

1) Depending on the configuration, a firmware update can take up to several minutes.

Status-LEDs right

| Figure | LED ¹⁾ | Terminal | Color | Status | Description |
|--------|-------------------|----------|-------|--------|----------------------------|
| | 1 | X3 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 2 | X4 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 3 | X5 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 4 | X6 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 5 | X2 | Green | On | Measurement range: 1 A |
| | | | Red | On | Measurement range: 5 A |

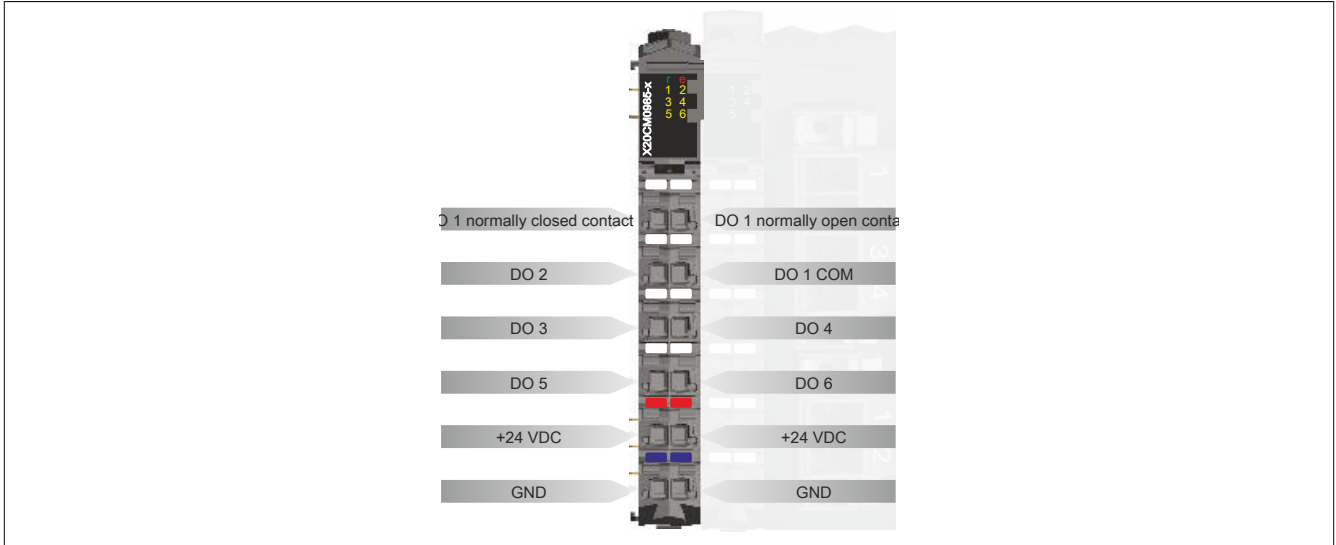

1) LEDs 1 - 5 are green/red dual LEDs.

9.26.4.7 Connection elements

9.26.4.8 Digital outputs X1

Terminals X1 and X2 can be keyed differently to prevent unintentional incorrect connection on the module.

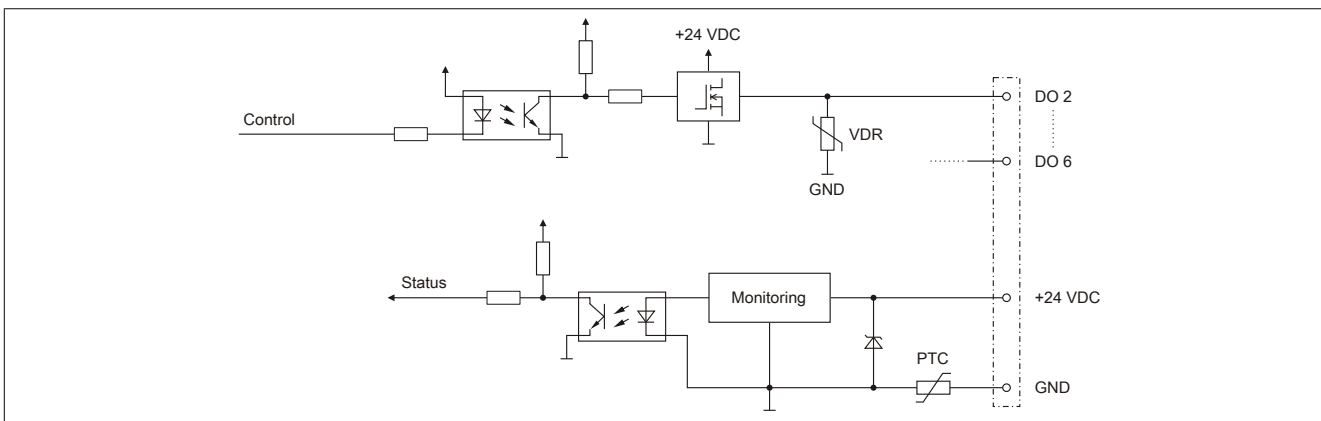

Function description of the digital outputs

| Digital output | Description |
|----------------|--|
| DO1 | <p>This digital output is designed as a changeover contact switch. The monitoring relay is used for optional monitoring of the following measured values of the generator mains:</p> <ul style="list-style-type: none"> • Overvoltage and undervoltage • Overfrequency and underfrequency • Voltage asymmetry • Current asymmetry • Calculated neutral conductor current (maximum) • Short circuit current • Rating-dependent overcurrent • Limit value of the capacitive reactive power (exciter failure) • Generator overload • Generator feedback |
| DO2 | DO2 serves as a meter output. The generated pulses can be recorded by an external energy meter (kWh). |
| DO3 | This output is set when there is no voltage on the bus bar (below the lower limit of the defined parameter). 3-phase monitoring takes place for the bus bar voltage. |
| DO4 | DO4 serves as a synchronization pulse. The power switch is activated by setting this output. The output is deactivated after the configured time has elapsed (exception:Synchro check operating mode). |
| DO5 | <p>This output can be configured either as a digital output or monitoring output (see register "ConfigOutput24" on page 2951). The monitoring function is only available with the "3-phase mains" configuration. When configured as monitoring output, the user can choose between monitoring the following mains measurement values:</p> <ul style="list-style-type: none"> • Overvoltage and undervoltage • Overfrequency and underfrequency • Voltage asymmetry • Phase shift • Frequency change <p>The monitoring status can be output either normally or inverted. This can be defined using the "DigitalOutput" on page 2983 register. This setting is then disabled when shutting off, resetting, restarting, etc.</p> |
| DO6 | <p>Can be configured as a digital output or synchronization output (see register "ConfigOutput24" on page 2951).</p> <p>When configured as a synchronization output: DO6 serves as the synchronization pulse. The power switch is activated by setting this output. The output is deactivated after the configured time has elapsed (exception:Synchro check operating mode).</p> |

DO1 - Output circuit diagram

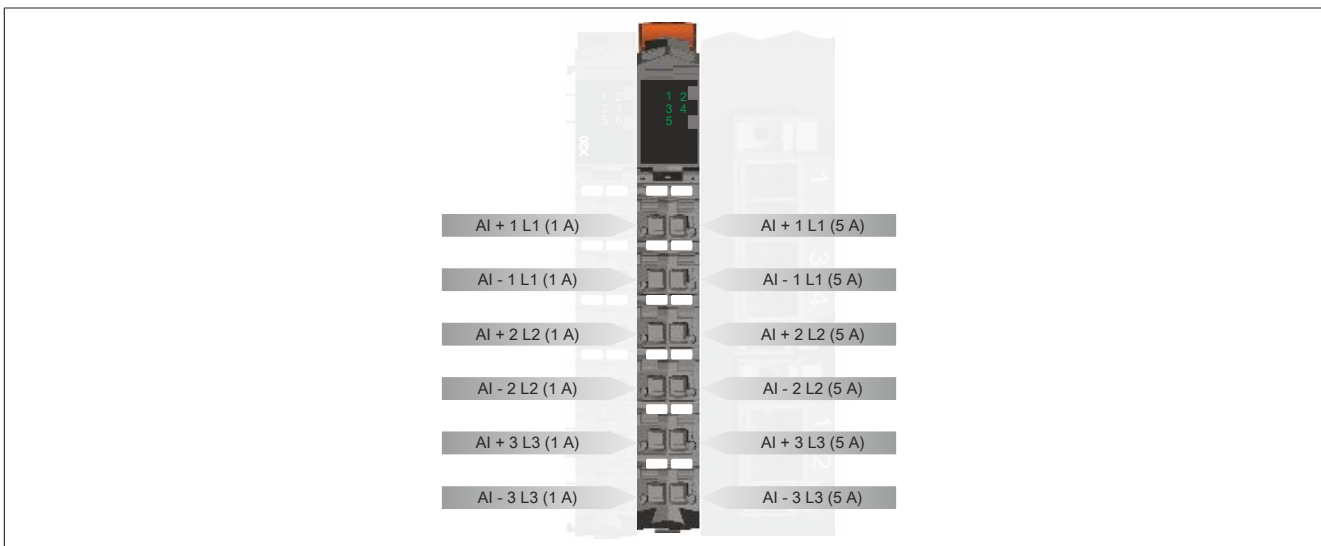

DO2 - DO 6 - Output circuit diagram

9.26.4.9 X2 analog current inputs

The X2 terminal measures the three phase currents of the generator mains using an externally connected current transformer. The measurement range of the current inputs can be configured as 1 A or 5 A.

Terminals X1 and X2 can be keyed differently to prevent unintentional incorrect connection on the module.

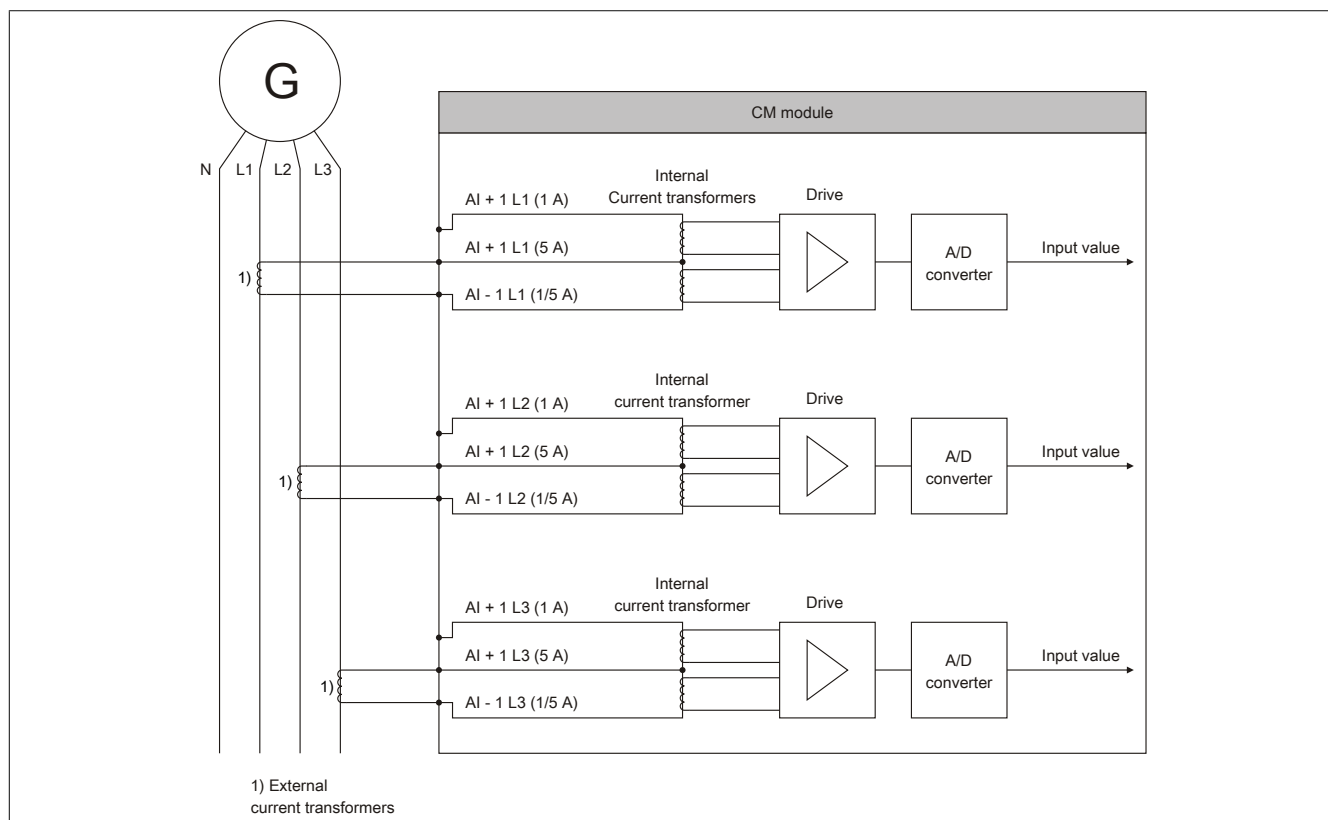

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

Input circuit diagram - Analog current inputs

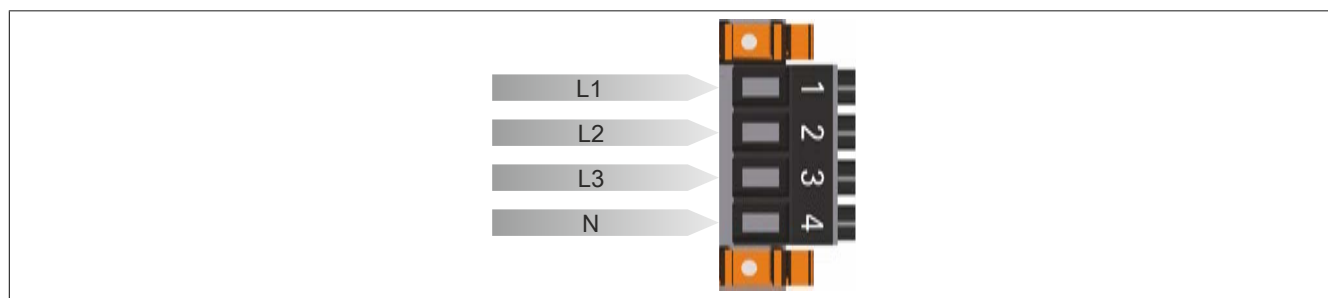

9.26.4.10 X3 and X5 analog voltage inputs

The X3 and X5 terminals are used to measure and monitor the line-to-line and phase voltages of the generator mains and bus bar.

- Terminal X3: Generator mains
- Terminal X5: Bus bar

Terminals X3 and X5 are keyed differently to prevent unintentional incorrect connection on the module. Section ["Releasing the locking clip for terminals X3 - X6" on page 2937](#) describes how to release the terminal locking clip.

9.26.4.11 X4 and X6 analog voltage inputs

Terminals X4 and X6 are keyed differently to prevent unintentional incorrect connection on the module. Section "Releasing the locking clip for terminals X3 - X6" on page 2937 describes how to release the terminal locking clip.

The two terminals are connected differently depending on the selected configuration (see register "ConfigOutput68" on page 2950).

Configuration as Sync-mains 1 / Sync-mains 2

The voltage inputs on the X4 and X6 terminals are used to determine the line-to-line voltages for synchronization between two different mains networks.

- Terminal X4: Synchronization mains network 1
- Terminal X6: Synchronization mains network 2

Configuration as 3-phase mains

The terminals X4 and X6 can be combined to form a 3-phase mains. The X4 and X6 terminals are used to measure and monitor the line-to-line voltages and phase voltages of the power mains.

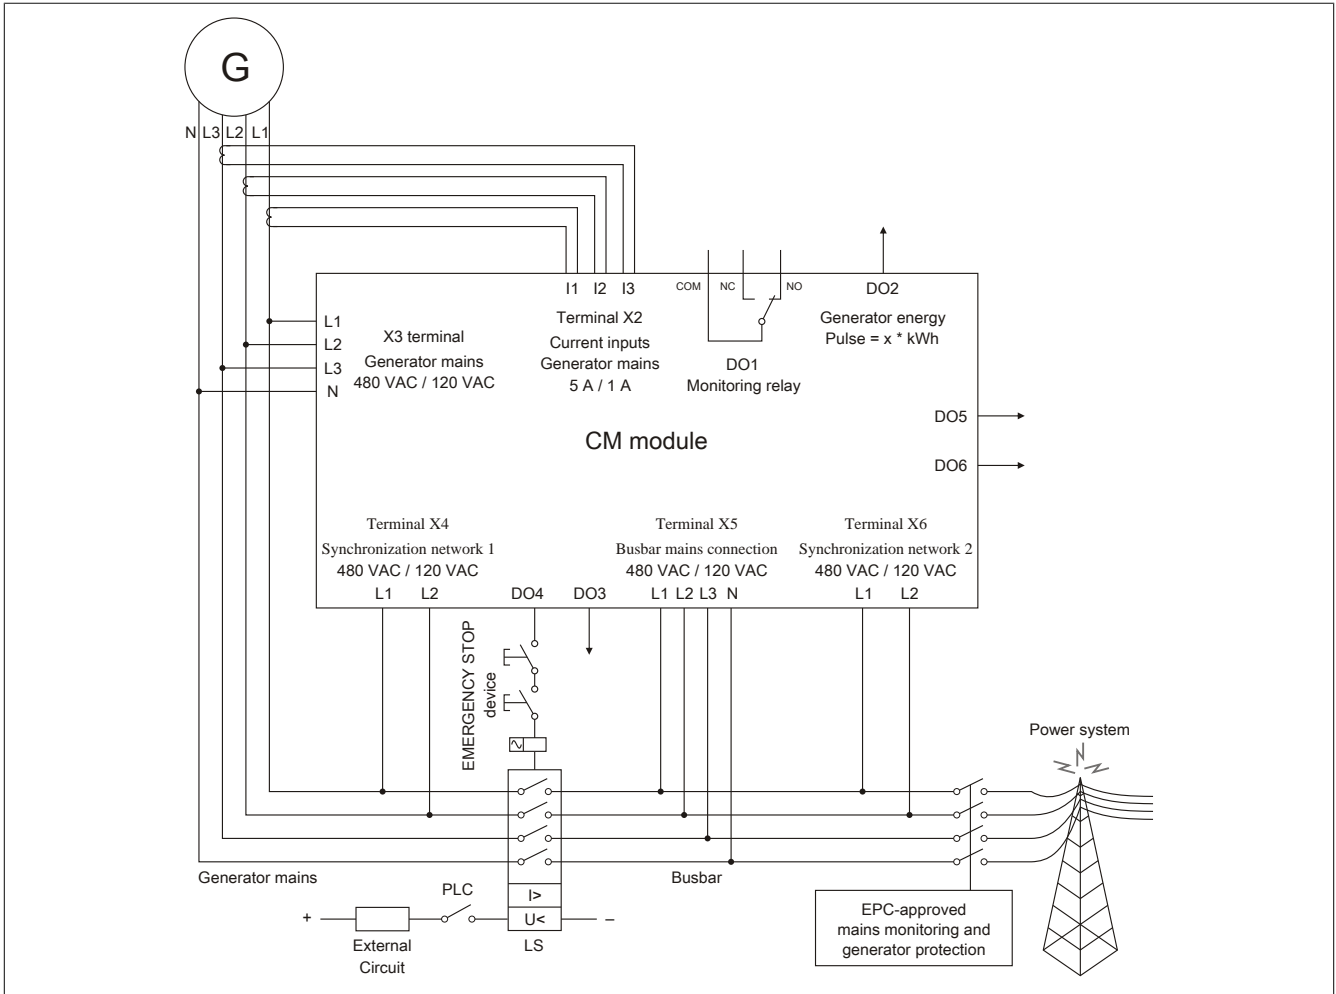

Input circuit diagram, analog voltage inputs

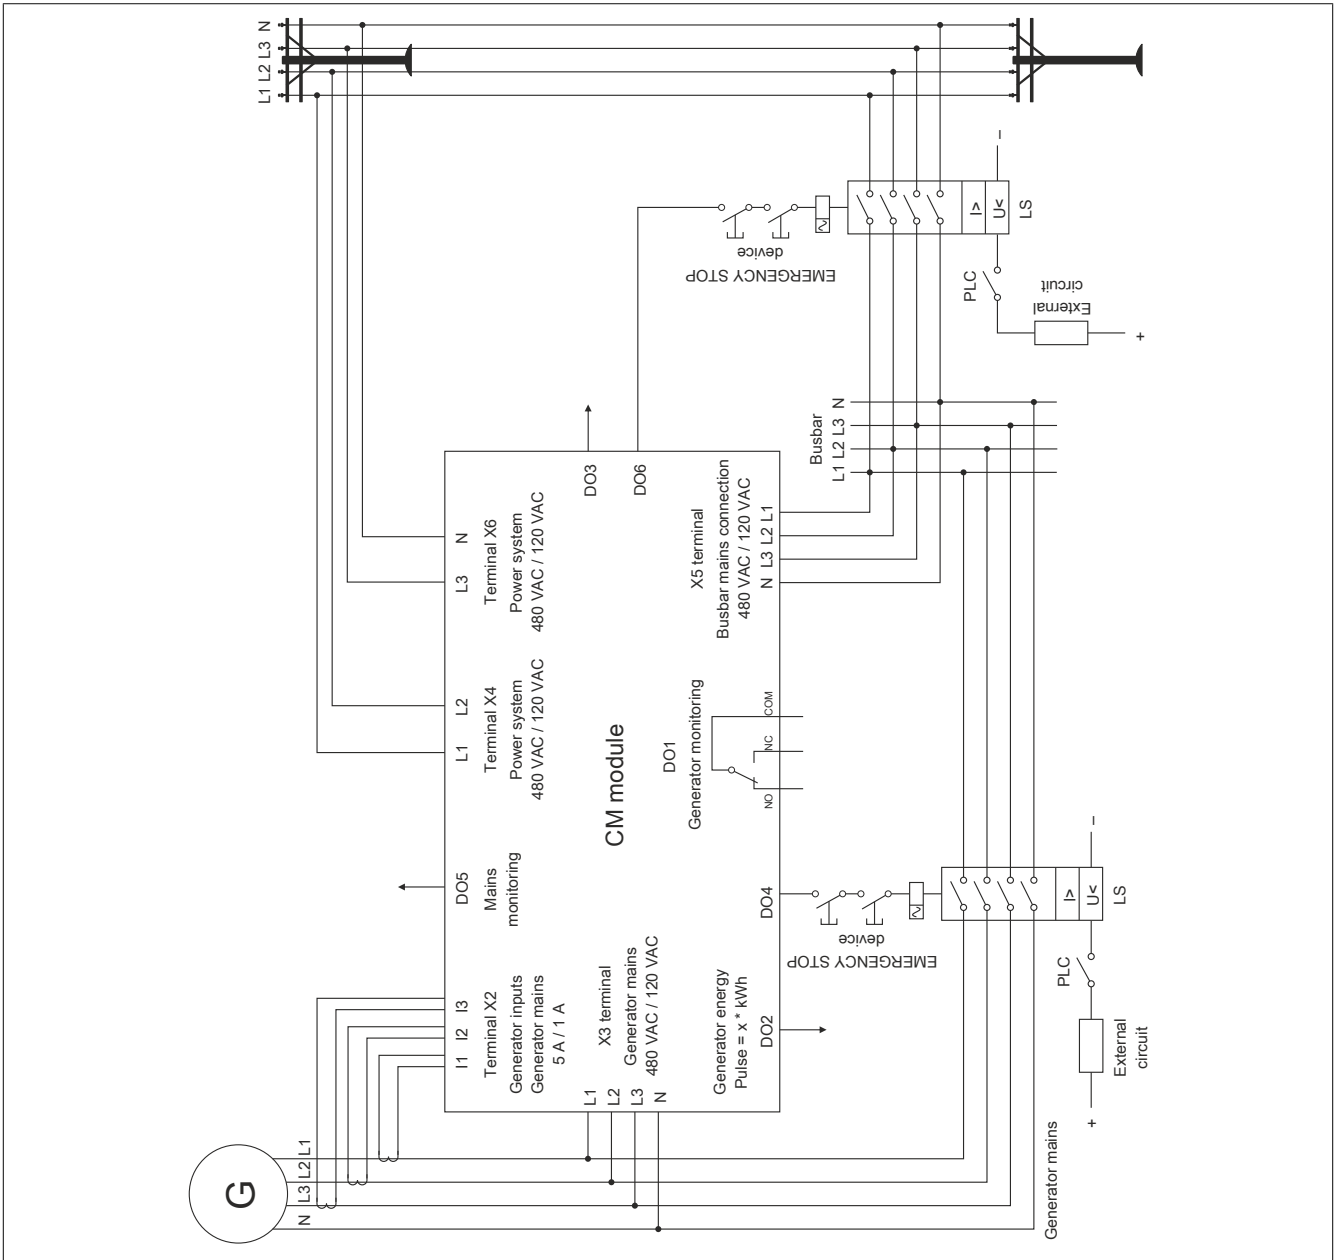

9.26.4.12 Circuit diagram

Example of mains configuration "Sync-mains 1 / Sync-mains 2"

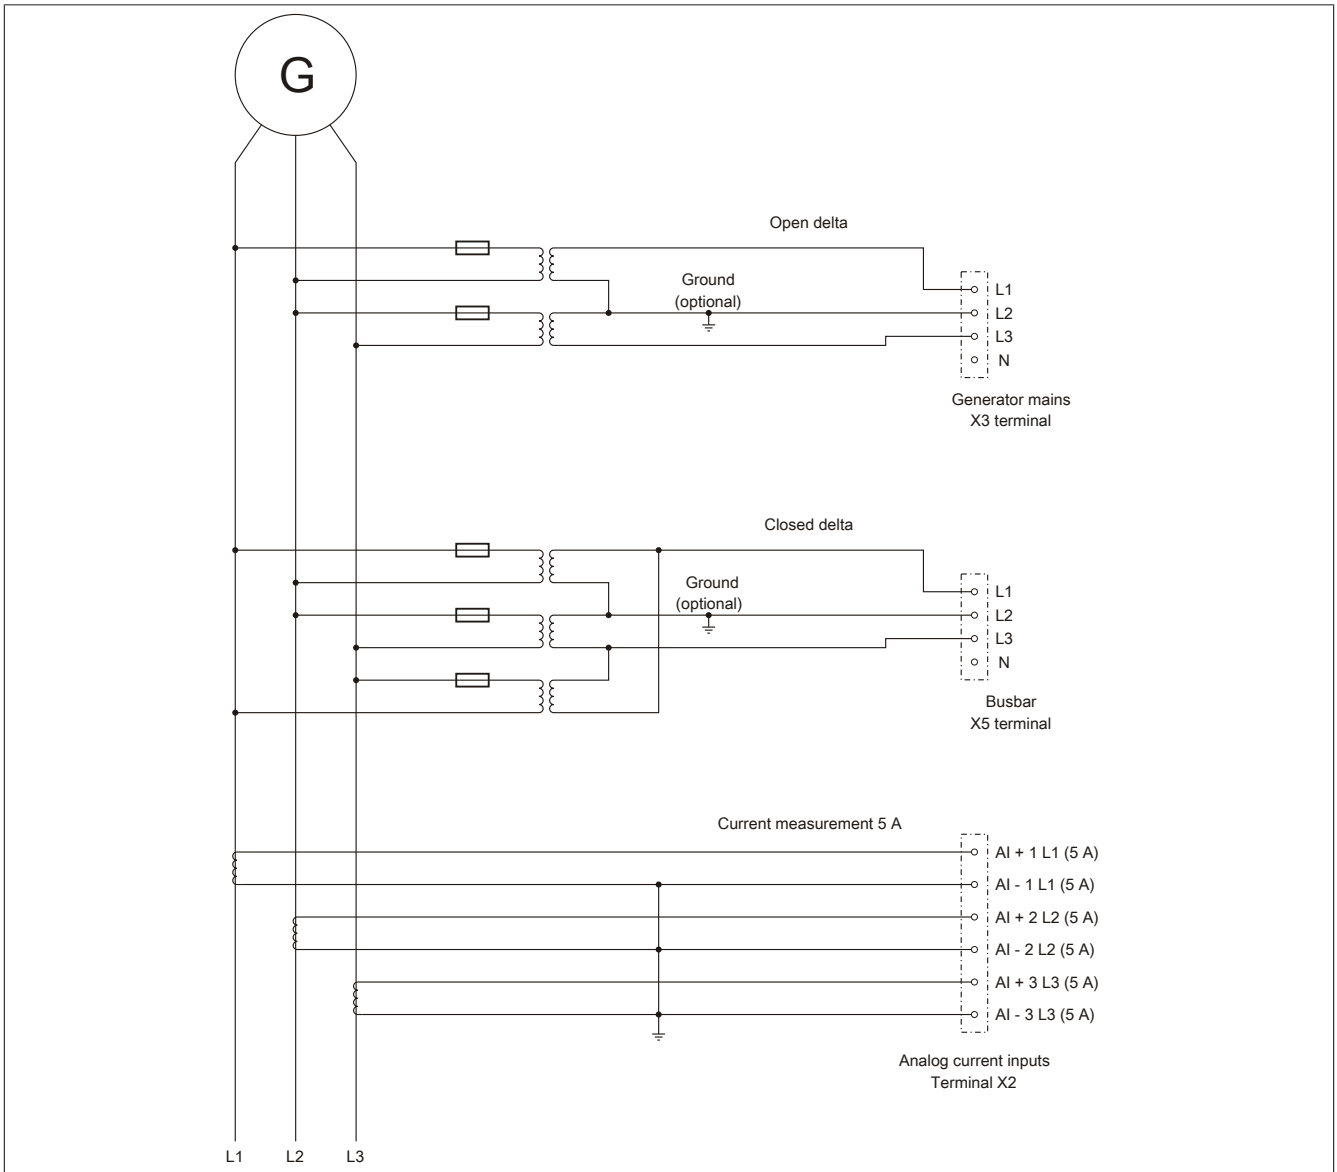

Example of mains configuration "3-phase mains"

9.26.4.13 Typical connection examples for voltage/current measurement

For power measurement, the X3 terminal must always be used in connection with the X2 terminal! For single-phase measurement, always ensure that current input 1 is used for power measurement if voltage input 1 is being used. Otherwise, accurate power measurement is not possible for this phase!

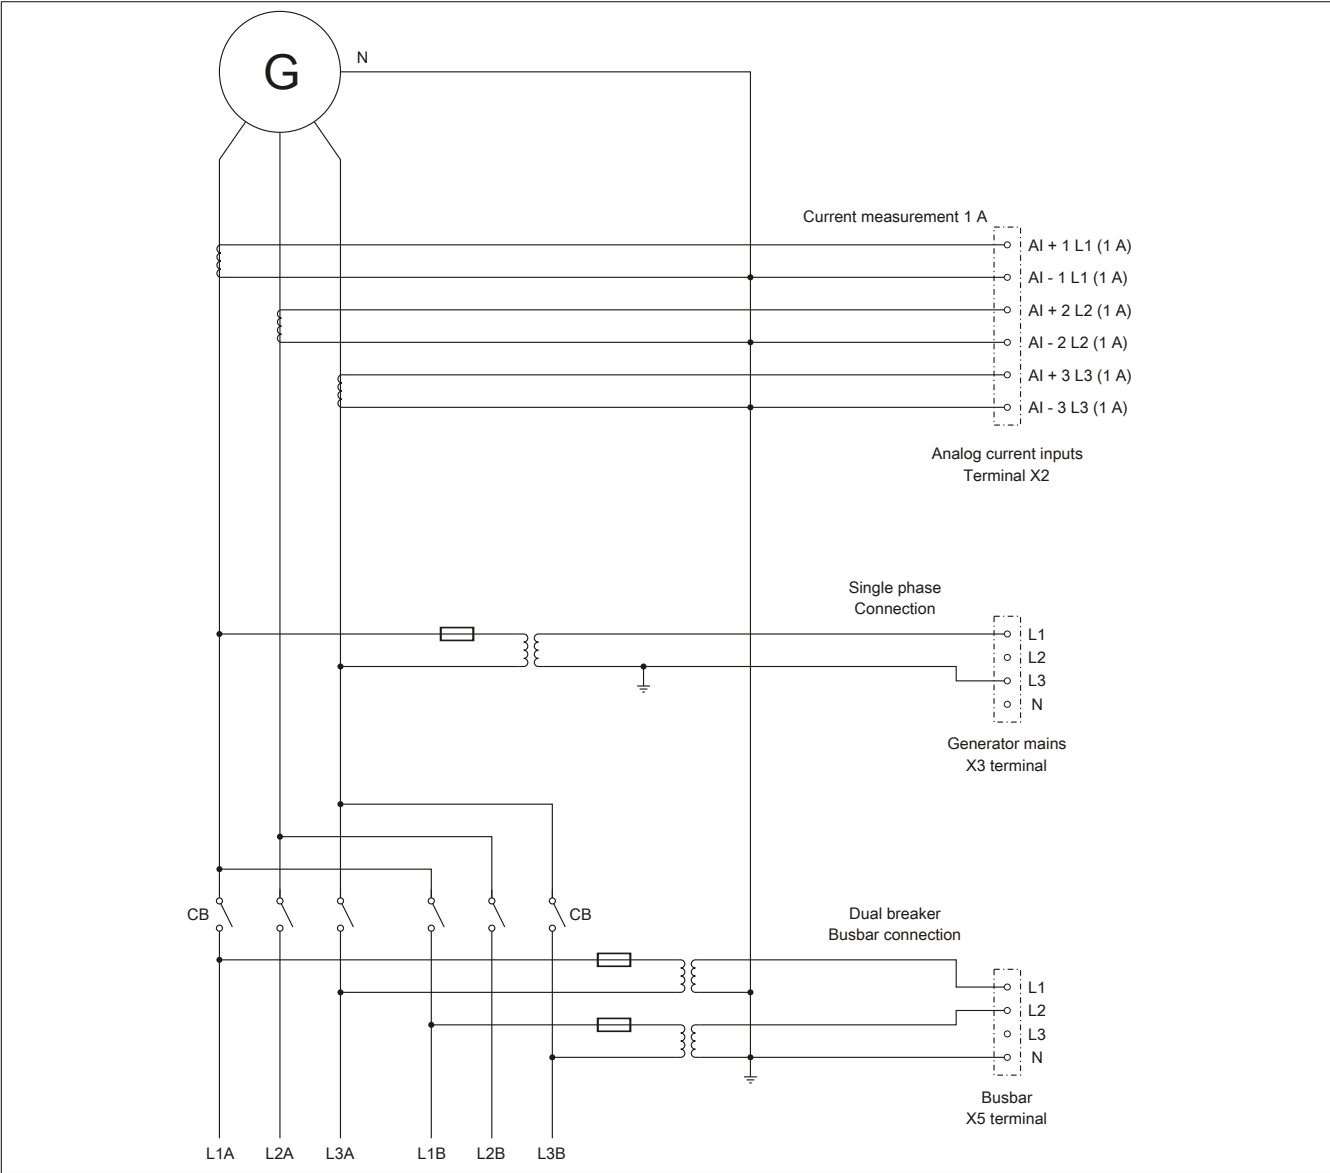

Connection example 1

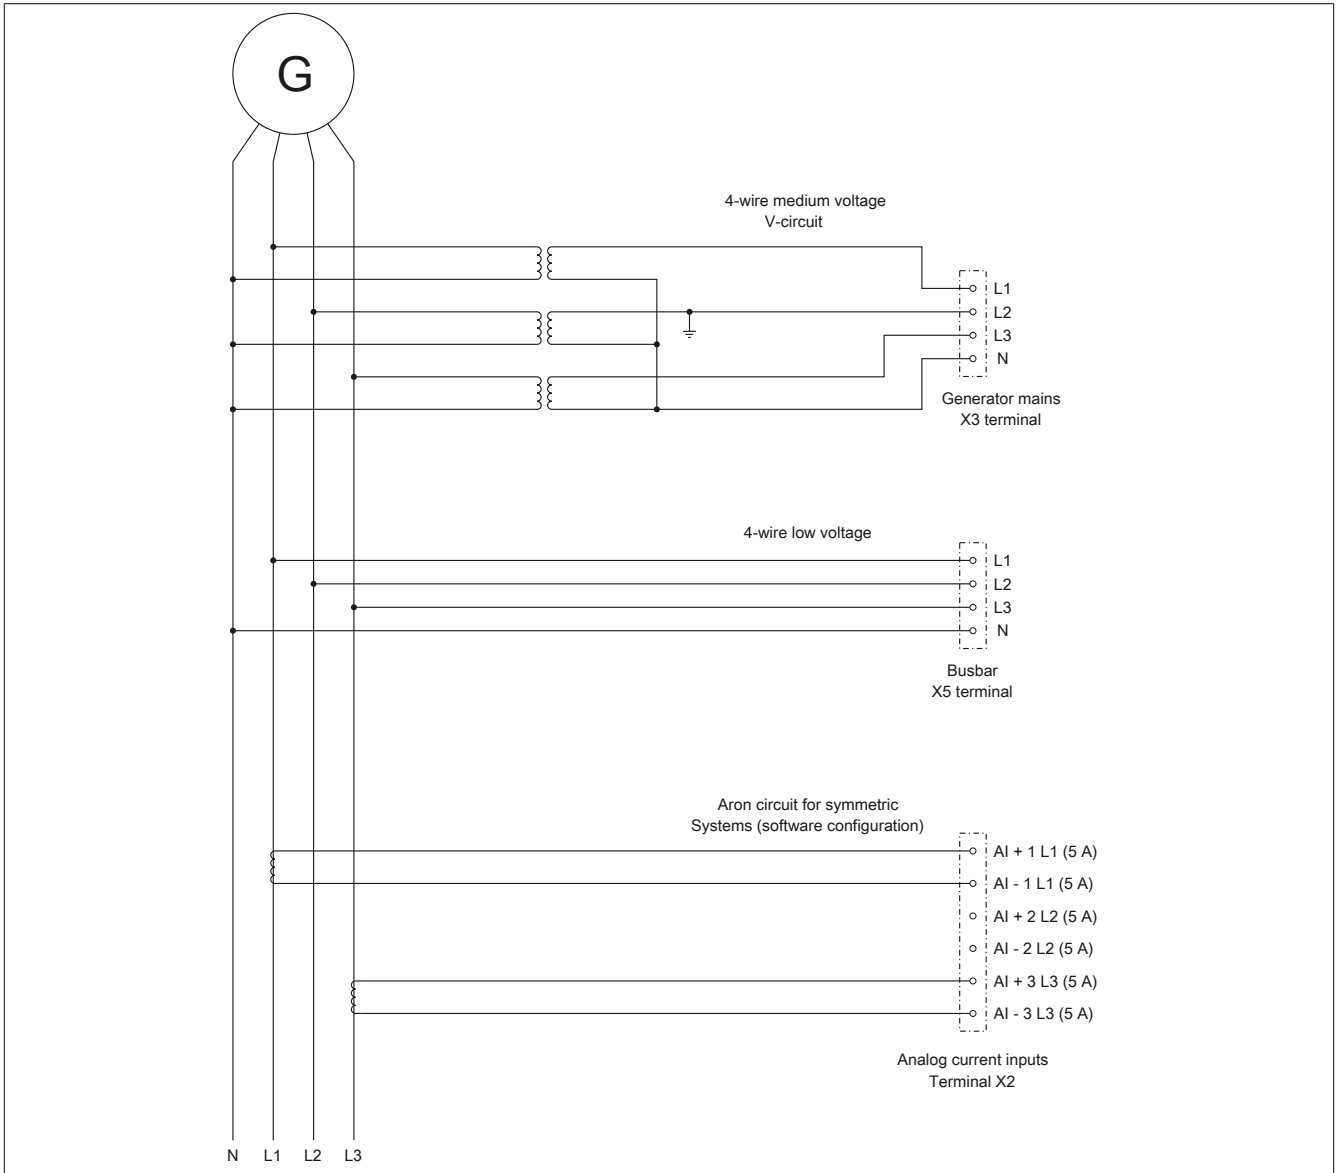

Connection example 2

Connection example 3

Connection example 4

9.26.4.14 Electrical service life

The electrical service life for the DO1 relay output can be seen in the following diagram.

9.26.4.15 Releasing the locking clip for terminals X3 - X6

Terminals X3 - X6 are equipped with a terminal locking clip. This clip attaches the terminal block securely to the electronic module. This prevents the terminal from accidentally being disconnected.

To release the locking clip, press inwards on the corrugated part of the lever with your fingertip (1) and then slide outwards (2). No additional tools are required for removing the terminal.

Terminals X5 and X6 must be removed first before terminals X3 and X4 can be removed.

9.26.4.16 Synchronization functions

The following three synchronization functions are available on the module:

- "Synchronization with slip" on page 2938
- "Synchro check" on page 2938
- "Switching to voltage-free "dead bus"" on page 2939

Synchronization with slip

The following is valid for synchronization mains 1 and synchronization mains 2:

- $50\% < U < 125\%$ of the nominal voltage U_N
- $80\% < f < 110\%$ of the nominal frequency f_N

The generator voltage is adjusted to the synchronization voltage with regard to amplitude and frequency. Taking into account the configured phase angle ($\Delta\alpha$), a defined transformer vector group and the switching response time, the switch-on command is calculated and transmitted in advance so that the main contacts of the power switch are closed at the point of synchronicity.

Synchronization occurs under the following conditions:

- Synchronization mode "Slip" is set using software.
- The device is ready.
- The phase sequences of the mains networks being synchronized are OK (phase sequence detection).
- The configured limit for voltage difference is not exceeded (ΔU_{\max}).
- The configured limits for frequency difference are not exceeded (Δf_{\max} and Δf_{\min}).
- The configured limit for the phase angle (including vector group transformer $\Delta\alpha$) is not exceeded (j_{\max}).

When the synchronization mode is set to "Slip", synchronization is not activated until the value of the differential angle between the two synchronized mains networks is $>5^\circ$ for at least 100 ms.

In other words, if the phase difference happens to be within $\pm 5^\circ$ at the time of the synchronization request, the synchronization won't be activated unless/until the phase difference is larger for 100 ms.

Resetting the mode "Synchronization with slip" cancels the synchronization.

In order to receive a synchronization pulse, the synchronization window must be entered from any phase direction after the synchronization command has been authorized and all of the synchronization conditions specified above are observed.

The switch is not engaged immediately after reaching the phase window. The switch is only engaged if synchronization is possible at the synchronization point while observing the switch lead time.

With very low frequency differences or equivalent frequencies and in adherence to the conditions described above, synchronization will also take place at a phase angle = 0° .

The synchronization output changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

Synchro check

In this operating mode, the device can be used to check the synchronization. The DO4 output remains set as long as the following conditions are met:

- The "-Check" command is set using software.
- The device is ready.
- The phase sequences of the mains networks being synchronized are OK (phase sequence detection).
- The configured limit for voltage difference is not exceeded (ΔU_{\max}).
- The configured limits for frequency difference are not exceeded (Δf_{\max} and Δf_{\min}).
- The defined limit for the phase angle is not exceeded (ϕ_{\max}).

DO4 stays at High as long as all conditions are met.

Switching to voltage-free "dead bus"

The switch-on command for the power switch is output without synchronization if the following conditions have been met:

- The "Dead Bus" command is set using software.
- The device is ready.
- The bus bar does not have voltage applied: $U_B < U_{BminSync}$ as a percentage of U_{NomBus}

| | |
|--------------------|-------------------------|
| U_B ... | Bus bar phase voltage |
| $U_{BminSync}$... | Dead bus voltage |
| U_{NomBus} ... | Bus bar nominal voltage |

DO4 changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

9.26.4.17 Measurement functions

Timing diagram

Measured parameters for generator mains (X3)

- Phase currents
- Current average
- Dynamic current average
- Neutral current
- Line-to-line voltages
- Phase voltages
- Voltage average
- Total apparent power
- Total reactive power
- Total active power
- Active power factor
- Frequency

Measured parameters between synchronization mains networks

- Differential angle
- Differential voltage

Rating-dependent overcurrent

Rating-dependent overcurrent monitoring is in accordance with the specifications of IEC 255-8 "Electrical relay; Relay for protecting against thermal overload (overload relay)" and IEC 255-17 "Electrical relay; Relay for protecting against the thermal overload of motors (overload relay for motors).

Dependent delayed imbalanced load monitoring

Dependent delayed imbalanced load monitoring protects against imbalanced loads in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An imbalanced load can be caused by uneven current distribution in the mains due to imbalanced load, asymmetrical short circuits, line interruptions or switching operations. Imbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An imbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an imbalanced load occurs, the characteristics that trigger imbalanced load protection should be adapted to the thermal characteristics of the generator. Imbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

Short circuit current monitoring

If overcurrent or a short circuit occurs and the limit value is exceeded, the error message "Short circuit current" is signaled after the configured time delay has passed.

Voltage asymmetry monitoring

This trigger value, specified as a percentage, is based on the nominal voltage of the generator. If the difference between the three line-to-line voltages of the generator mains exceeds the set limit value, then the error message "Voltage asymmetry" is signaled after the response time has passed. For this to happen, only one of these voltages has to exceed the respective limit value (in either the positive or negative direction).

Bus bar voltage measurement and zero voltage monitoring

3-phase monitoring takes place for the bus bar voltage. The measured values are represented as phase-to-phase and phase-to-neutral values. The DO3 output is set when there is no voltage (below the lower limit of the defined limit bus bar voltage minimum U_{Bmin}) on the bus bar (X5 terminal).

This monitoring can be used to determine which synchronization function should be used.

| Synchronization function | Bus bar voltage measurement |
|---------------------------|---|
| Dead bus | No voltage is being supplied to the bus bar or the value is below the lower limit parameter. Output DO3 is set. |
| Synchronization with slip | The voltage measured on the bus bar is above the defined parameter value. Output DO3 is not set. |

Exciter failure

The reactive power monitoring can be used to protect a generator against operating in the impermissible range. The capacitive reactive power monitor offers protection against under-excitation (exciter failure). If the lower limit is exceeded (in the negative direction), the error message "Capacitive reactive power" is signaled after the configured time delay has passed.

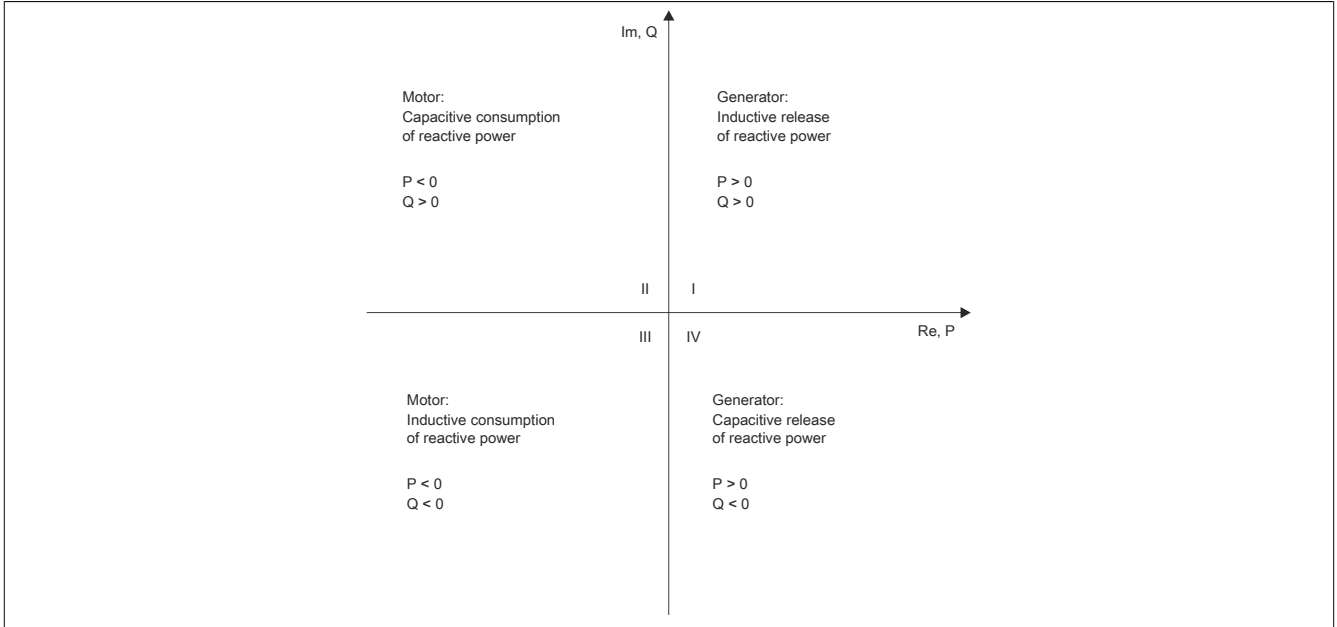

Phase sequence detection

Phase sequence detection is used to detect incorrectly wired voltage and current inputs or if the generator is rotating in the wrong direction (for information about configuration, see register "[ConfigOutput24](#)" on page 2951).

Phase sequence L1, L2 and L3 is monitored for this. If not correct, then an error message is output (see register "[StatusDigitalOutput](#)" on page 2983) and synchronization cannot take place.

9.26.4.18 Generator operating modes

The operating modes possible for the generator are illustrated in this 4 quadrant diagram.

Quadrant I

Generator operation, inductive release of reactive power:

- The active power P and the reactive power Q are greater than 0.
- The phase angle ϕ is between 0 and 90° . This means that U keeps ahead of I .

Example: $\phi = 30^\circ$

Quadrant II

Motor operation, capacitive reactive power consumption:

- The active power P is less than 0 while the reactive power Q is greater than 0.
- The phase angle ϕ is between 90 and 180° . This means that U keeps ahead of I .

Example: $\phi = 150^\circ$

**Quadrant III**

Motor operation, inductive reactive power consumption:

- The active power P and the reactive power Q are less than 0.
- The phase angle ϕ is between -90 and -180° . This means that U lags behind I .

Example: $\phi = -150^\circ$

Quadrant IV

Generator operation, capacitive release of reactive power:

- The active power P is greater than 0 while the reactive power Q is less than 0.
- The phase angle ϕ is between 0 and -90° . This means that U lags behind I.

Example: $\phi = -30^\circ$

Power factor of the generator

The power factor is a product of the ratio between the active power P and apparent power S. With sinusoidal values, this corresponds to the cosine of the phase shift angle ϕ .

$$|\text{Power factor}| = \left| \frac{P}{S} \right|$$

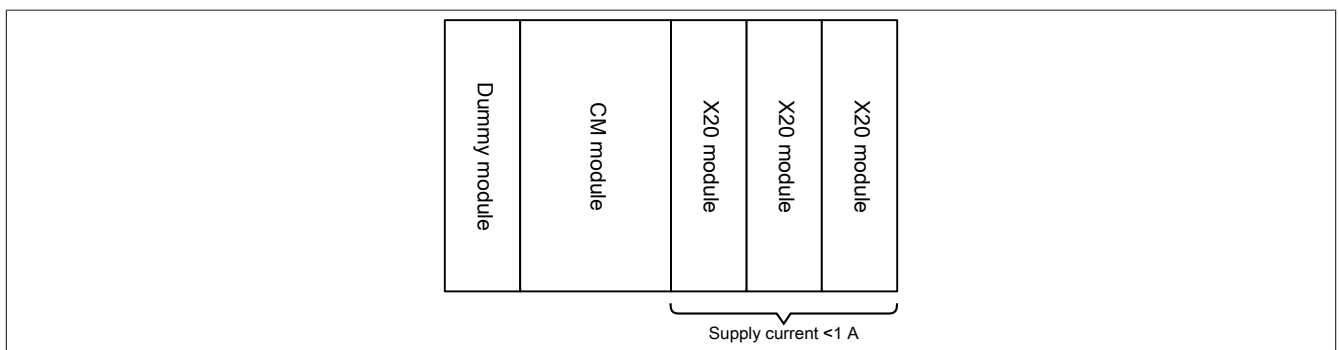

The module derives the sign used for the power factor from the signs used with the P and Q values. In this way, it depends on the generator's operating mode:

| Sign | Description |
|----------|--|
| Positive | <ul style="list-style-type: none"> • Quadrant I or III, P and Q positive or P and Q negative • Inductive release of reactive power or inductive reactive power consumption |
| Negative | <ul style="list-style-type: none"> • Quadrant II or IV, P negative and Q positive or P positive and Q negative • Capacitive release of reactive power or capacitive reactive power consumption |

9.26.4.19 Derating

Derating does not need to be taken into account for operation below 55°C .

For operation above 55°C , a dummy module must be connected to the left of the module. A maximum supply current of 1 A is permitted to pass through the module to the modules connected to the right.

9.26.4.20 Register description

9.26.4.20.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.26.4.20.2 Function model 0 - default

1) This configuration register has a dual design. The register with "Read" in the name allows the configured value to be read back.

9.26.4.20.2.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.4.20.3 Configuration registers

9.26.4.20.3.1 General registers

Mains settings

Name:

ConfigOutput68

ConfigOutput68Read

This register is used to configure the module on the connected mains.

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|-------------------------------|----------|---|
| 0 - 1 | Generator mains configuration | 00 | 3-phase network with neutral conductor |
| | | 01 | 3-phase mains without neutral conductor |
| | | 10 to 11 | Reserved |
| 2 - 3 | Busbar configuration | 00 | 3-phase network with neutral conductor |
| | | 01 | 3-phase mains without neutral conductor |
| | | 10 to 11 | Reserved |
| 4 - 5 | Mains configuration | 00 | 3-phase network with neutral conductor |
| | | 01 | 3-phase mains without neutral conductor |
| | | 10 | Sync network 1 / Sync network 2 |
| | | 11 | Reserved |
| 6 - 7 | Reserved | 0 | |
| 8 - 9 | Generator mains ground | 00 | No phases grounded |
| | | 01 | L1 grounded |
| | | 10 | L2 grounded |
| | | 11 | L3 grounded |
| 10 - 11 | Busbar ground | 00 | No phases grounded |
| | | 01 | L1 grounded |
| | | 10 | L2 grounded |
| | | 11 | L3 grounded |
| 12 - 13 | Sync Mains 1 ground | 00 | No phases grounded |
| | | 01 | L1 grounded |
| | | 10 | L2 grounded |
| | | 11 | L3 grounded |
| 14 - 15 | Sync Mains 2 ground | 00 | No phases grounded |
| | | 01 | L1 grounded |
| | | 10 | L2 grounded |
| | | 11 | L3 grounded |

Mains without neutral conductor

If configured as "3-phase mains without neutral conductor", the potential of the neutral conductor is calculated from the 3 phases ("virtual neutral point").

The phase voltages are then measured in relation to this "virtual neutral point".

Mains with ground

If one of the phases of a mains system is grounded, then it must be configured as such. Otherwise, it is possible that the module will report a phase failure that blocks the mains synchronization function.

Monitoring functions disabled:

- Phase failure monitoring is not carried out for the phase configured as "grounded".
- Phase sequence monitoring is not performed on 2-phase mains that are grounded.

Mains configuration

The mains can be used as two 2-phase synchronization mains or combined into a 3-phase mains.

If the mains configuration is set to "3-phase mains" then the monitoring functions will be enabled for these combined mains.

Nominal voltage range, nominal current range and Aron circuit

Name:

ConfigOutput20

ConfigOutput20Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---|-------|---|
| 0 | Nominal voltage range of generator mains | 0 | Voltage 100 V |
| | | 1 | Voltage 400 V |
| 1 | Nominal voltage range of busbar | 0 | Voltage 100 V |
| | | 1 | Voltage 400 V |
| 2 | Nominal voltage range of Sync Mains 1 | 0 | Voltage 100 V |
| | | 1 | Voltage 400 V |
| 3 | Nominal voltage range of Sync Mains 2 | 0 | Voltage 100 V |
| | | 1 | Voltage 400 V |
| 4 | Nominal current range of the generator mains | 0 | Current range 1 A |
| | | 1 | Current range 5 A |
| 5 | Switch to power measurement principle of Aron circuit | 0 | Aron circuit disabled: Three-phase supply with neutral line |
| | | 1 | Aron circuit enabled: Three-phase supply without neutral line |
| 6 - 7 | Reserved | 0 | |

Nominal frequency (f_{Nom})

Name:

ConfigOutput10

ConfigOutput10Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|--------------|-----------------------------|------------|
| UINT | 4800 to 6200 | corresponds to 48 to 62 Hz. | 0.01 Hz |

General configuration register

Name:

ConfigOutput24

ConfigOutput24Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|----------|---|
| 0 - 1 | DO5 function | 00 | DO5 is freely available to the user |
| | | 01 | Monitoring output of the mains |
| | | 10 | DO5 is freely available to the user or can be used as a mains monitoring output (the two signals are linked with an OR) |
| | | 11 | Reserved |
| 2 - 3 | DO6 function | 00 | DO6 is freely available to the user |
| | | 01 | Synchronization output (control of power switch) |
| | | 10 to 11 | Reserved |
| 4 | Definition of rotational direction monitoring of all mains | 0 | Right rotating field |
| | | 1 | Left rotating field |
| 5 - 7 | Reserved | 0 | |

Trigger bits

Name:

ConfigOutput23

ConfigOutput23Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------------|-------|--|

| | | 1 | On rising edge: Unbalanced load meter set to 0 |
| 1 - 7 | Reserved | 0 | |

9.26.4.20.3.2 Generator mains**Nominal voltage of generator mains (U_{NomGen})**

Name:

ConfigOutput02

ConfigOutput02Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|------------------------------|------------|
| UINT | 70 to 65000 | Corresponds to 70 to 65000 V | 1 V |

Multiplier for generator mains

Name:

ConfigOutput06

ConfigOutput06Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

The value 100 corresponds to a multiplication factor of 1 (measured value not changed).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------------------|------------|
| UINT | 1 to 65535 | Corresponds to 0.01 to 655.35 | 0.01 |

Nominal current of generator mains (I_{Nom})

Name:

ConfigOutput04

ConfigOutput04Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-----------------------------|------------|
| UINT | 0 to 65000 | Corresponds to 0 to 65000 A | 1 A |

Multiplier for current transformer

Name:

ConfigOutput09

ConfigOutput09Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|---------------------------|------------|
| UINT | 1 to 65535 | Corresponds to 1 to 65535 | 1 |

Turns generator mains functions on/off

Name:

ConfigOutput21

ConfigOutput21Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|---|
| 0 | Error acknowledgment mode | 0 | Error bits are reset by the module |
| | | 1 | Error bits are reset by the user |
| 2 - 3 | Check all overvoltages and undervoltages ¹⁾ | 00 | 3 phase voltages |
| | | 01 | 3 line-to-line voltages |
| | | 10 | 3 line-to-line and 3 phase voltages |
| | | 11 | Reserved |
| 4 - 5 | Reserved | 0 | |
| 6 | Power measurement mode ²⁾ | 0 | Total output - Including the harmonic component |
| | | 1 | Fundamental power - 1st harmonic only |
| 7 | Reserved | 0 | |

1) This parameter is supported starting with upgrade 1.6.0.0 (firmware version 102). For information about configuring limit values, see "[Generator monitoring](#)" on page 2954.

2) This parameter is supported starting with upgrade 1.5.0.0 (firmware version 101).

Power measurement mode

In real transmission networks, neither the voltages nor the currents are strictly sinusoidal. This means: The fundamental frequencies are generally subject to strong harmonics.

By default, the module always accounts for the contributions of the fundamental frequency as well as the harmonics. In addition to the voltage and current measured values, this also affects the power measurements.

When controlling with reactive power in applications, the part of the reactive power coming from the harmonic frequencies (distortion reactive power) can have negative effects. Only the displacement reactive power should be controlled (i.e. the reactive power component of the fundamental frequency). In particular, this can make a control to displacement reactive power = 0 ($\cos \varphi = 1$) impossible.

This is why the module offers the possibility of accounting for only the fundamental frequency (1st harmonic) for power measurement, when necessary. This primarily serves to filter out the distortion reactive power. However, all other measured values associated with the power measurement as well as the corresponding generator protection functions are affected when re-configuring the power measurement to the fundamental frequency.

The voltage and current measured values from the generator mains are **not** affected. Just as before (as with the other voltage supply systems), they also always include the contribution of harmonics regardless of the mode being used for power measurement.

| Measured value / Functionality | Corresponding data point | Corresponding output | Remarks/Details |
|--|--------------------------------|----------------------|--|
| Active power | AnalogInput19 | | P → P_H1 |
| Reactive power | AnalogInput20 | | Q → Q_H1 |
| Apparent power | AnalogInput21 | | S → S_H1 |
| Power factor | AnalogInput23 | | Power factor → $\cos \varphi$ $ \cos \varphi = \cos(\arctan(Q_H1/P_H1))$ The signs for $\cos \varphi$ are described in section " Generator operating modes " on page 2941. "I" and "U" must be replaced by the respective 1st harmonics "I_H1" and "U_H1". |
| Maximum total active power | ConfigOutput52 | | Changing the parameter "Power measurement mode" during runtime has no immediate effect on any of these registers or the internal energy meters (e.g. meter reset). It only determines the summands or comparison value that is effective immediately (total output / fundamental frequency power). |
| Active energy meter for supply | ConfigOutput54 | | |
| Reactive energy meter for supply | ConfigOutput55 | | |
| Active energy meter for reference | ConfigOutput71 | | |
| Reactive energy meter for reference | ConfigOutput72 | | |
| Energy meter output | | DO 2 | |
| Generator monitoring function: Capacitive reactive power | StatusInput10 | DO 1 | |
| Generator monitoring function: Generator overload | StatusInput31 | DO 1 | |
| Generator monitoring function: Generator feedback | StatusInput32 | DO 1 | |

Low-pass filter for total power ratings

Name:

ConfigOutput41

ConfigOutput41Read

Parameter for delay time of the low-pass filter of the total power values P, Q and S or P_H1, Q_H1 and S_H1 (see "Power measurement mode" on page 2953). The maximum total power values are recorded independently of this without being filtered.

This parameter is used as a delay element so that current or voltage fluctuations have less effect on how the calculated power values are represented. The damping behavior of the low-pass filter acts in accordance with the configurable time constant of a decaying e-function.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|----------------------------|------------|
| UINT | 0 to 300 | Corresponds to 0 to 300 ms | 1 ms |

9.26.4.20.3.3 Generator monitoring**Overvoltage limit of generator mains (U_{max})**

Name:

ConfigOutput16 (1st value)

ConfigOutput118 (2nd value)

ConfigOutput16Read (1st value)

ConfigOutput118Read (2nd value)

If the value of one of the generator voltages configured in the "ConfigOutput21" on page 2953 register exceeds the value set here, then the "Overvoltage" error message (register "StatusInputPacked01" on page 2984) or "Overvoltage2" (register "StatusInputPacked05" on page 2987) is indicated after the delay time has expired and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of U_{NomGen} | 0.1% |

Response time for generator overvoltage (U_{max})

Name:

ConfigOutput26 (1st time)

ConfigOutput119 (2nd time)

ConfigOutput26Read (1st time)

ConfigOutput119Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|----------------------------|------------|
| UINT | 5 to 100 | Corresponds to 0.5 to 10 s | 0.1 s |

Undervoltage limit of generator mains (U_{min})

Name:

ConfigOutput27 (1st value)

ConfigOutput59 (2nd value)

ConfigOutput27Read (1st value)

ConfigOutput59Read (2nd value)

If the value of one of the generator voltages configured in the "ConfigOutput21" on page 2953 register falls below the value set here, then the "Undervoltage" or "Undervoltage2" error message (register "StatusInputPacked01" on page 2984) is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of U_{NomGen} | 0.1% |

Response time for generator undervoltage (U_{min})

Name:

ConfigOutput28 (1st time)

ConfigOutput65 (2nd time)

ConfigOutput28Read (1st time)

ConfigOutput65Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|----------------------------|------------|
| UINT | 5 to 100 | Corresponds to 0.5 to 10 s | 0.1 s |

Generator over-frequency (f_{max})

Name:

ConfigOutput29 (1st frequency)

ConfigOutput122 (2nd frequency)

ConfigOutput29Read (1st frequency)

ConfigOutput122Read (2nd frequency)

If the value of the generator frequency exceeds the percent value set here in relation to the nominal frequency, then the error message "Overfrequency" (register "[StatusInputPacked01](#)" on page 2984) or "Overfrequency 2" (register "[StatusPacked05](#)" on page 2987) is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|----------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} | 0.1% |

Response time for generator over-frequency (f_{max})

Name:

ConfigOutput30 (1st time)

ConfigOutput123 (2nd time)

ConfigOutput30Read (1st time)

ConfigOutput123Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|------------------|------------|
| UINT | 5 to 100 | For 0.5 for 10 s | 0.1 s |

Generator under-frequency (f_{min})

Name:

ConfigOutput31 (1st frequency)

ConfigOutput120 (2nd frequency)

ConfigOutput31Read (1st frequency)

ConfigOutput120Read (2nd frequency)

If the value of the generator frequency falls below the percent value set here in relation to the nominal frequency, then the error message "Underfrequency" (register "[StatusInputPacked01](#)" on page 2984) or "Underfrequency 2" (register "[StatusInputPacked05](#)" on page 2987) is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|----------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} | 0.1% |

Response time for generator under-frequency (f_{\min})

Name:

ConfigOutput32 (1st time)

ConfigOutput121 (2nd time)

ConfigOutput32Read (1st time)

ConfigOutput121Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Generator voltage asymmetry (U_{as})

Name:

ConfigOutput33

ConfigOutput33Read

This trigger value, specified as a percentage, is based on the nominal voltage of the generator. If the difference between the three line-to-line voltages of the generator mains exceeds the configured limit value, then the error message "Voltage asymmetry" is indicated (register "[StatusInputPacked01](#)" on page 2984) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

For this to happen, only one of these voltages has to exceed the respective limit value (in either the positive or negative direction).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|------------------------------|------------|
| UINT | 0 to 300 | For 0 to 30% of U_{NomGen} | 0.1% |

Response time for generator voltage asymmetry (U_{as})

Name:

ConfigOutput34

ConfigOutput34Read

This error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Load time constant for current asymmetry ($K1$)

Name:

ConfigOutput35

ConfigOutput35Read

The dependent delayed unbalanced load monitoring function (see "[Dependent delayed unbalanced load monitoring](#)" on page 2957) continually monitors the AC currents coming from the main current converters and continually calculates the present unbalanced load current. This is compared with the threshold value, which is calculated using the load time constants. If this threshold value is exceeded, the error message "Current asymmetry" is indicated (register "[StatusInputPacked01](#)" on page 2984) and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|---------------------|------------|
| UINT | 1 to 65535 | For 0.1 to 6553.5 s | 0.1 s |

Unbalanced load constant (K2)

Name:

ConfigOutput109

ConfigOutput109Read

The boundary between continuous operation and short-term operation is defined by the unbalanced load constant K2 (see "[Dependent delayed unbalanced load monitoring](#)" on page 2957).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|---------|------------------|------------|
| UINT | 8 to 15 | For 0.08 to 0.15 | 0.01 |

Dependent delayed unbalanced load monitoring

Unbalanced load monitoring protects against unbalanced load in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An unbalanced load can be caused by uneven current distribution in the mains due to unbalanced load, asymmetrical short circuits, line interruptions or switching operations. Unbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An unbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an unbalanced load occurs, the characteristics that trigger unbalanced load protection should be adapted to the thermal characteristics of the generator. Unbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

When unbalanced load protection is tripped can be calculated using the following formula:

| Operating mode | Formula |
|--|--|
| Short-term operation | $t = \frac{K1}{\left(\frac{I_2}{I_{Nom}}\right)^2 - K2^2}$ |
| Continuous operation | $\frac{I_2}{I_{Nom}} \leq K2 \rightarrow t = \infty$ |
| Key t Calculated tripping time K1 Valid load time constant for the generator [s] K2 Unbalanced load constant I ₂ Calculated inverse current / unbalanced load current [A] I _{Nom} Nominal current for the generator [A] | |

To calculate the tripping time instant, the scan duration of the measurement system (i.e. 20 ms for 50 Hz voltage) is divided by the calculated trigger time, and the results are continually added up. With short-term operation, the value of the summands increases; with continuous operation, it decreases. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

The boundary between continuous operation and short-term operation is defined by the unbalanced load constant K2.

Information:

When the generator is at a standstill, the summand is neither reset nor is its value reduced.

Nominal current on generator mains for unbalanced load protection

Name:

ConfigOutput124

ConfigOutput124Read

The nominal current for unbalanced load protection can be set separately. If the value is set to 0, the normal nominal current is used for calculations.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|------------------|------------|
| UINT | 0 to 65000 | For 0 to 65000 A | 1 A |

Maximum limit of neutral conductor current

Name:

ConfigOutput36

ConfigOutput36Read

Configurable limit for the neutral conductor current. If the value is exceeded, then the error message "Maximum neutral conductor current" is indicated (register "[StatusInputPacked01](#)" on page 2984) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|----------------------------|------------|
| UINT | 0 to 1000 | For 0 to 100% of I_{Nom} | 0.1% |

Response time for neutral conductor current monitor

Name:

ConfigOutput37

ConfigOutput37Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Short circuit current

Name:

ConfigOutput38

ConfigOutput38Read

If the value of the generator current exceeds the percentage based on the converter's nominal current set here, then the error message "Short circuit current" is indicated (register "[StatusInputPacked01](#)" on page 2984) and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|--------------|------------------------------|------------|
| UINT | 1000 to 5000 | For 100 to 500% of I_{Nom} | 0.1% |

Response time for short circuit current

Name:

ConfigOutput39

ConfigOutput39Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 4 to 500 | For 0.04 to 5 s | 0.01 s |

Rating-dependent overcurrent

Name:

ConfigOutput42

ConfigOutput42Read

The response value percentage is based on the nominal current of the generator. If the response value is exceeded, then the error message "Rating-dependent overcurrent" is indicated (register "[StatusInputPacked01](#)" on page 2984) and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|--------------|------------------------------|------------|
| UINT | 1000 to 2000 | For 100 to 200% of I_{Nom} | 0.1% |

Rating-dependent overcurrent monitoring

A generator that is operated at its nominal current I_{Nom} normally reaches about half of its maximum thermal load. Operating it above the rated current I_{Nom} result in additional warming, which is permitted until the maximum temperature is reached. The highest permissible continuous temperature is determined by the class of the insulation material used in the generator.

Based on the settings and the current measurement, the device forms an internal model based on an I^2t characteristic curve of the generator temperature. This allows the heat capacity of the generator to be completely utilized for short overloads while at the same time providing full protection. The configurable parameters for determining the machine model include the nominal current I_{Nom} of the generator and the time multiplier.

Integration coefficient for rating-dependent overcurrent (iths)

Name:

ConfigOutput43

ConfigOutput43Read

To calculate the tripping time instant, the sampling duration of the measurement system is divided by the calculated trigger time (t). The results are continually added up. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|---------|--------------|------------|
| UINT | 1 to 20 | For 0.1 to 2 | 0.1 |

For a constant overcurrent, the trigger characteristic curve can be calculated based on the following formula:

$$t = \frac{0.14}{\left(\frac{I}{I_N}\right)^{0.02} - 1} * iths$$

Key:

| | |
|-------|---|
| t | Tripping time [s] |
| I | The highest value of the 3 phase currents [A] |
| I_N | Rating-dependent overcurrent [A] |
| iths | Integration coefficient |

Trigger characteristic curve in accordance with IEC 255-4 (normal, inverse)

The monitor function can be reset by restarting the module or by falling below the overcurrent value so that the results of the continuous addition decrease according to the formula.

Capacitive reactive power

Name:

ConfigOutput44

ConfigOutput44Read

The capacitive reactive power for the generator is monitored to determine if it falls below the defined response value. In this way, monitoring the capacitive reactive power can be used to detect exciter failure. If the response value is fallen below, then the error message "Capacitive reactive power" is indicated (register "[StatusInputPacked01](#)" on [page 2984](#)) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Depending on how the "Power measurement mode" parameter is set in the "[ConfigOutput21](#)" on [page 2953](#) register, either the total reactive power or the fundamental frequency reactive power (displacement reactive power) is compared with the response value.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------------|--------------------------|------------|
| INT | -32768 to 32767 | For -32768 to 32767 kvar | 1 kvar |

Response time for reactive power monitoring

Name:

ConfigOutput45

ConfigOutput45Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Generator overload

Name:

ConfigOutput89

ConfigOutput89Read

If the value of the active power of the generator exceeds the percentage of the generator's nominal power set here, then the error message "Generator overload" is indicated (register "[StatusInputPacked01](#)" on [page 2984](#)) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Depending on how the "Power measurement mode" parameter is set in the "[ConfigOutput21](#)" on [page 2953](#) register, either the total active power or the fundamental frequency active power is compared with the response value.

The nominal power is calculated as follows:

$$P_{\text{NomGen}} = U_{\text{NomGen}} * I_{\text{NomGen}} * \sqrt{3}$$

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--------------------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of P_{NomGen} | 0.1% |

Response time for generator overload

Name:

ConfigOutput90

ConfigOutput90Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Generator feedback

Name:

ConfigOutput91

ConfigOutput91Read

If the value of the negative active power of the generator falls below the percentage of the generator's nominal power set here, then the error message "Generator feedback" is indicated (register "[StatusInputPacked01](#)" on page 2984) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Depending on how the "Power measurement mode" parameter is set in the "[ConfigOutput21](#)" on page 2953 register, either the total active power or the fundamental frequency active power is compared with the response value.

The nominal power is calculated as follows:

$$P_{\text{NomGen}} = U_{\text{NomGen}} * I_{\text{NomGen}} * \sqrt{3}$$

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|----------------------------------|------------|
| UINT | 0 to 2000 | 0 to 200% of P_{NomGen} | 0.1% |

Response time for generator feedback

Name:

ConfigOutput92

ConfigOutput92Read

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

DO1 function

This digital output can be set after the defined response time has elapsed depending on the assignment of the generator mains' monitoring variables (X3). Assignments are made using the "ConfigOutput57" on page 2963 and "ConfigOutput97" on page 2964 registers.

The monitoring variables can be assigned to this input either individually or with additional monitoring variables using an OR connective. This makes it possible to set the relay when there are multiple monitoring variables.

Assigning monitoring functions - 1

Name:

ConfigOutput57

ConfigOutput57Read

The following monitoring functions can be assigned to the monitoring relay using this register:

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|---|-------|------------------------|
| 0 | Overvoltage (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 1 | Undervoltage (or a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 2 | Overfrequency | 0 | Do not assign function |
| | | 1 | Assign function |

| | | 1 | Assign function |
| 13 - 14 | Reserved | 0 | |
| 15 | Undervoltage 2 (one phase) | 0 | Do not assign function |
| | | 1 | Assign function |

Information:

The minimum pulse duration when addressing a monitoring function on the error bit via X2X as well as on the relay is 500 ms.

Assigning monitoring functions - 2

Name:

ConfigOutput97

The following additional monitoring functions can be assigned to the monitoring relay using this register:

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------------------|-------|------------------------|
| 0 | Overvoltage 2 (one phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 1 | Underfrequency 2 | 0 | Do not assign function |
| | | 1 | Assign function |
| 2 | Overfrequency 2 | 0 | Do not assign function |
| | | 1 | Assign function |
| 3 - 15 | Reserved | 0 | |

Information:

The minimum pulse duration when addressing a monitoring function on the error bit via X2X as well as on the relay is 500 ms.

9.26.4.20.3.4 Synchronization mains

(for mains configuration "Sync mains 1 / Sync mains 2")

Nominal voltage of synchronization mains (U_{NomSyn})

Name:

ConfigOutput01

ConfigOutput01Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------------|------------|
| UINT | 70 to 65000 | For 70 to 65000 V | 1 V |

Multiplier for synchronization mains

Name:

ConfigOutput07 (mains 1)

ConfigOutput08 (mains 2)

ConfigOutput07Read (mains 1)

ConfigOutput08Read (mains 2)

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 means a multiplier factor of 1 (measured value not changed).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|--------------------|------------|
| UINT | 1 to 65535 | For 0.01 to 655.35 | 0.01 |

9.26.4.20.3.5 Mains

Mains (for mains configuration "3-phase mains")

Nominal voltage of mains (U_{NomMains})

Name:

ConfigOutput01

ConfigOutput01Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------------|------------|
| UINT | 70 to 65000 | For 70 to 65000 V | 1 V |

Multiplier for mains

Name:

ConfigOutput07

ConfigOutput07Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 means a multiplier factor of 1 (measured value not changed).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|--------------------|------------|
| UINT | 1 to 65535 | For 0.01 to 655.35 | 0.01 |

Enable/disable mains functions

Name:

ConfigOutput22

ConfigOutput22Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|--|
| 0 | Error acknowledgment mode | 0 | Mains error bits are reset by the module |
| | | 1 | Mains error bits are reset by the user |
| 1 | Phase shift measurement | 0 | Three-phase only |
| | | 1 | Single- or three-phase |
| 2 - 3 | Check all overvoltages and undervoltages ¹⁾ | 00 | 3 phase voltages |
| | | 01 | 3 line-to-line voltages |
| | | 10 | 3 line-to-line and 3 phase voltages |
| | | 11 | Reserved |
| 4 | Configuration of undervoltage monitoring | 0 | 2-point mode |
| | | 1 | 6-point mode |
| 5 - 7 | Reserved | 0 | |

- 1) This parameter is supported starting with upgrade 1.6.0.0 (firmware version 102). For information about configuring limit values, see "Mains voltage monitoring" on page 2966.

9.26.4.20.3.6 Mains monitoring functions

(for "3-phase mains" configuration)

The following mains monitoring functions are available if the network configuration is set to a 3-phase mains (see register "Mains settings" on page 2950).

Mains voltage monitoring**Overvoltage limit of the mains ($U_{\max\text{Mains}}$)**

Name:

ConfigOutput73 (1st value)

ConfigOutput98 (2nd value)

ConfigOutput73Read (1st value)

ConfigOutput98Read (2nd value)

If the value of one of the mains voltages configured in the "ConfigOutput22" on page 2965 register exceeds the value set here, then the "Overvoltage" error message (register "StatusInputPacked02" on page 2985) or "Overvoltage 2" (register "StatusInputPacked04" on page 2986) is indicated after the delay time has expired and, if configured, the DO5 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 2000 | For 0 to 200% of U_{NomMains} | 0.1% |

Response time for mains overvoltage (U_{MaxMains})

Name:

ConfigOutput82 (1st time)

ConfigOutput99 (2nd time)

ConfigOutput82Read (1st time)

ConfigOutput99Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Mains over-frequency ($f_{\max\text{Mains}}$)

Name:

ConfigOutput75 (1st frequency)

ConfigOutput102 (2nd frequency)

ConfigOutput75Read (1st frequency)

ConfigOutput102Read (2nd frequency)

If the value of the mains frequency exceeds the percent value set here in relation to the nominal frequency, then the error message "Overfrequency" (register "StatusInputPacked02" on page 2985) or "Overfrequency 2" (register "StatusInputPacked04" on page 2986) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-----------------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} | 0.1% |

Response time for mains over-frequency ($f_{\max\text{Mains}}$)

Name:

ConfigOutput84 (1st time)
 ConfigOutput103 (2nd time)
 ConfigOutput84Read (1st time)
 ConfigOutput103Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Mains under-frequency ($f_{\min\text{Mains}}$)

Name:

ConfigOutput76 (1st frequency)
 ConfigOutput104 (2nd frequency)
 ConfigOutput76Read (1st frequency)
 ConfigOutput104Read (2nd frequency)

If the value of the mains frequency falls below the percent value set here in relation to the nominal frequency, then the error message "Underfrequency" (register "[StatusInputPacked02](#)" on page 2985) or "Underfrequency 2" (register "[StatusInputPacked04](#)" on page 2986) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-----------------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} | 0.1% |

Response time for mains under-frequency ($f_{\min\text{Mains}}$)

Name:

ConfigOutput85 (1st time)
 ConfigOutput105 (2nd time)
 ConfigOutput85Read (1st time)
 ConfigOutput105Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Mains voltage asymmetry (U_{asMains})

Name:

ConfigOutput77
 ConfigOutput77Read

This trigger value, specified as a percentage, is based on the nominal voltage of the mains. If the difference between the 3 line-to-line voltages of the mains exceeds the configured limit value, then the error message "Voltage asymmetry" is indicated (register "[StatusInputPacked02](#)" on page 2985) after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

For this to happen, only one of these voltages has to exceed the respective limit value (in either the positive or negative direction).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|---------------------------------------|------------|
| UINT | 0 to 300 | For 0 to 30% of U_{NomMains} | 0.1% |

Response time for the mains voltage asymmetry ($U_{asMains}$)

Name:

ConfigOutput86

ConfigOutput86Read

This error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------------|------------|
| UINT | 5 to 100 | For 0.005 to 0.1 s | 0.001 s |

Undervoltage monitoring in 2-point mode

2 independent limit values and response times can be defined for undervoltage monitoring.

Undervoltage limit of the mains ($U_{minMains}$)

Name:

ConfigOutput74

ConfigOutput74Read

If the value of one of the mains voltages configured in the "ConfigOutput22" on page 2965 register falls below the value set here, then the "Undervoltage" error message (register "StatusInputPacked02" on page 2985) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|---------------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of $U_{NomMains}$ | 0.1% |

Undervoltage limit 2 of the mains ($U_{minMains}$)

Name:

ConfigOutput100

ConfigOutput100Read

If the value of one of the linked mains voltages falls below the value set here, then the "Undervoltage" error message (register "StatusInputPacked02" on page 2985) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-----------------------------|------------|
| UINT | 0 to 2000 | 0 to 200% of $U_{NomMains}$ | 0.1% |

Response time for mains undervoltage ($U_{minMains}$)

Name:

ConfigOutput83 (1st time)

ConfigOutput101 (2nd time)

ConfigOutput83Read (1st time)

ConfigOutput101Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Undervoltage monitoring in 6-point mode

Up to 6 limit values and response times can be set for undervoltage monitoring. If not all 6 points are required, then unused limit values and response times should be set to 0.

Note that for each point, the specified limit value and response time must be greater than or equal to the preceding point ($P1 \leq P2 \leq P3$, etc.).

The defined points are used to create a limit value curve. If the voltage drops below the curve and a response time has expired, the error message "Undervoltage" is signaled ("[StatusInputPacked02](#)" on [page 2985](#) register). If configured, the D05 monitoring relay is also switched.

A faulty undervoltage monitoring configuration also triggers the "Undervoltage" error message, and monitor relay DO5 is switched if configured to do so (e.g. $P1 > P2$ and $P2$ not equal to (0% / 0 ms)).

The types of voltages to be monitored are specified in the mains configuration ("[ConfigOutput22](#)" on [page 2965](#) register):

- Line-to-line voltages
- Phase voltages
- Line-to-line and phase voltages

As soon as one of the monitored voltages drops below the limit curve, the corresponding time counter begins counting. The time counter is reset when all voltages are once again equal to or higher than the defined value.

The "Undervoltage" error message is generated when one of the time counters crosses over the limit curve.

Example 1 with 3 points:

In this example, 3 limit values are defined, along with the corresponding response times:

- P1 (70% / 150 ms)
- P2 (70% / 700 ms)
- P3 (90% / 1500 ms)
- P4 (0% / 0 ms)
- P5 (0% / 0 ms)
- P6 (0% / 0 ms)

**Notes regarding limit curve**

- The red line marks the lowest permitted value for monitored voltages.
- If 2 consecutive points have the same limit value, then the response time of the first point is applied. In the example above, this situation is shown with points 1 and 2.
- Between points 2 and 3 the curve has a positive linear slope. If one of the monitored voltages drops in this area, the module calculates the appropriate response time.

Determining the response time

- 1) Find voltage value on Y axis
- 2) Locate intersection on curve
- 3) Read the response time on the X axis

Example 2 with 4 points:

In this example, 4 limit values are defined, along with the corresponding response times:

- P1 (30% / 150 ms)
- P2 (70% / 700 ms)
- P3 (70% / 1500 ms)
- P4 (90% / 1500 ms)
- P5 (0% / 0 ms)
- P6 (0% / 0 ms)

**Notes regarding limit curve**

- The red line marks the lowest permitted value for monitored voltages.
- Between points 1 and 2 the curve has a positive linear slope. If one of the monitored voltages drops in this area, the module calculates the appropriate response time.
- If 2 consecutive points have the same limit value, then the response time of the first point is applied. In the example, this situation is shown with points 2 and 3.
- Points 1 and 2 are connected directly by a line with a positive slope. To avoid a direct connection between points 2 and 4, one would have to define another point between them with the same limit as point 2 and the same response time as point 4. In this case, that is point 3.

Determining the response time

- 1) Find voltage value on Y axis
- 2) Locate intersection on curve
- 3) Read the response time on the X axis

Undervoltage limit of the microgrid (U_{MinMains})

Name:

ConfigOutput74 (1st mains)
 ConfigOutput100 (2nd mains)
 ConfigOutput110 (3rd mains)
 ConfigOutput112 (4th mains)
 ConfigOutput114 (5th mains)
 ConfigOutput116 (6th mains)
 ConfigOutput74Read (1st mains)
 ConfigOutput100Read (2nd mains)
 ConfigOutput110Read (3rd mains)
 ConfigOutput112Read (4th mains)
 ConfigOutput114Read (5th mains)
 ConfigOutput115Read (6th mains)

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|------------------------------------|------------|
| UINT | 0 to 2000 | 0 to 200% of U_{NomMains} | 0.1% |

Response time for mains undervoltage (U_{minMains})

Name:

ConfigOutput83 (1st mains)
 ConfigOutput101 (2nd mains)
 ConfigOutput111 (3rd mains)
 ConfigOutput113 (4th mains)
 ConfigOutput115 (5th mains)
 ConfigOutput117 (6th mains)
 ConfigOutput83Read (1st mains)
 ConfigOutput101Read (2nd mains)
 ConfigOutput111Read (3rd mains)
 ConfigOutput113Read (4th mains)
 ConfigOutput115Read (5th mains)
 ConfigOutput117Read (6th mains)

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Microgrid monitoring

A microgrid is a small mains power grid that only supplies a limited area and generally is not connected to other mains grids, which means it can function autonomously. This is in contrast to a synchronous grid, in which multiple smaller mains grids are connected together and synchronized.

With microgrid monitoring, the mains is monitored for over/undervoltage. After a defined response time elapses, a corresponding error message is generated. Microgrid monitoring always checks the line-to-line voltages independently of the configuration in the "ConfigOutput22" on page 2965 register.

Overvoltage limit of the mains ($U_{\max\text{Mains}}$)

Name:

ConfigOutput106

ConfigOutput106Read

If the value of one of the linked mains voltages exceeds the value set here, then the "Microgrid monitoring" error message (register "StatusInputPacked04" on page 2986) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|------------------------------------|------------|
| UINT | 0 to 2000 | 0 to 200% of U_{NomMains} | 0.1% |

Undervoltage limit of the mains ($U_{\min\text{Mains}}$)

Name:

ConfigOutput107

ConfigOutput107Read

If the value of one of the linked mains voltages falls below the value set here, then the "Microgrid monitoring" error message (register "StatusInputPacked04" on page 2986) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 2000 | For 0 to 200% of U_{NomMains} | 0.1% |

Response time for microgrid limit

Name:

ConfigOutput108

ConfigOutput108Read

An error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------------|------------|
| UINT | 5 to 200 | For 0.005 to 0.2 s | 0.001 s |

Phase shift monitoring

A phase shift is an abrupt change to the voltage curve that can be caused by a significant change to the load.

In this case, the device recognizes a single change to the period duration. This changed period duration is compared with the calculated average value from past measurements. Monitoring takes place for three phases and if desired also for a single phase. The phase shift monitoring function is only active if the mains voltage is higher than the set percentage value based on the nominal voltage for the converter.

If the response value is exceeded, the error message "Phase shift" is indicated (register "StatusInputPacked02" on page 2985) and, if configured, the DO5 monitoring relay is switched.

Phase shift monitoring response time

A phase shift is indicated on output DO5 within 2 ms after detection of the phase shift (i.e. after zero crossing of the extended/shortened period), as long as this is configured accordingly.

Phase shift detection

Phase shift detection is configured in the "ConfigOutput22" on page 2965 register.

| Type of monitoring | Description |
|--|--|
| Only three-phase monitoring | Triggering takes place if the limit value for three-phase monitoring was exceeded on all 3 phases within 2 periods. |
| Single-phase or three-phase monitoring | Triggering takes place: <ul style="list-style-type: none"> • If the limit value for single-phase monitoring is exceeded on at least one of the 3 phases • If the limit value for three-phase monitoring was exceeded on all 3 phases within 2 periods. |

Phase shift monitoring detects an abrupt change to the period duration of the mains voltage.

The period duration of the current period is compared with the average value for the period duration over the past 4 periods. If the difference exceeds the set limit value, then triggering takes place immediately.

Limit value

Setting of the limit value takes place in 0.1° steps. The internal limit value in μs is calculated as follows:

$$t_{\text{hres}}[\mu\text{s}] = t_{\text{hres}}[0.1^\circ] \cdot \text{Period duration} / 3600$$

When do this, the period duration for the set nominal frequency is used.

Example

Calculation of $t_{\text{hres}}[\mu\text{s}]$ at 50 Hz (period duration = 20000 μs) and limit value of 7°:

$$t_{\text{hres}}[\mu\text{s}] = 70 \cdot 20000 \mu\text{s} / 3600 = 388.88 \mu\text{s} \text{ (rounded to } 389 \mu\text{s)}$$

If the period duration thus changes abruptly by more than +389 μs , triggering takes place.

Maximum phase difference for a single phase

Name:

ConfigOutput78

ConfigOutput78Read

Triggering occurs if the electrical angle of the voltage curve shifts by more than the set angle on at least one phase.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------|------------|
| UINT | 0 to 990 | For 0 to 99° | 0.1° |

Maximum phase difference for three phases

Name:

ConfigOutput79

ConfigOutput79Read

Triggering occurs if the electrical angle of the voltage curve shifts by more than the set angle on all 3 phases.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------|------------|
| UINT | 0 to 990 | For 0 to 99° | 0.1° |

Minimum voltage for phase shift monitoring

Name:

ConfigOutput88

ConfigOutput88Read

A minimum voltage can be set. Phase shift monitoring is only active if the voltage on all 3 phases exceeds this value.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|---------------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of $U_{NomMains}$ | 0.1% |

Mains frequency change

Response value for mains frequency change (df/dt)

Name:

ConfigOutput80

ConfigOutput80Read

For df/dt monitoring, the frequency change in each period is compared to the previous period.

If this value exceeds the configured limit value in each of the periods for the specified number of periods and the sign for the frequency change is always the same, the error message "Df/dt (mains frequency change)" is indicated (register "[StatusInputPacked02](#)" on page 2985) and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-------------------|------------|
| UINT | 0 to 1000 | For 0 to 100 Hz/s | 0.1 Hz/s |

Number of periods for mains frequency change (df/dt)

Name:

ConfigOutput87

ConfigOutput87Read

This register is used to define the number of periods for monitoring the mains frequency change. For activation, the response value must be continually exceeded at least for as many periods as specified in this register. The display of the error message on output DO5 takes place max. 2 ms after internal detection.

The value of this register can be read back.

Example

The maximum tripping time at 4 periods and 50 Hz mains frequency is calculated as follows:

Max. tripping time = $4 \times 20 \text{ ms} + 2 \text{ ms} = 82 \text{ ms}$

The change in period duration caused by the frequency gradients must also be accounted for.

| Data type | Value | Information | Resolution |
|-----------|----------|-------------|------------|
| UINT | 1 to 250 | - | - |

DO5 function**DO5 function**

Name:

ConfigOutput81

ConfigOutput81Read

This digital output can be set after the defined response time has elapsed depending on the assignment of the mains' monitoring variables.

The monitoring variables can be assigned to this input either individually or with additional monitoring variables using an OR operator. This makes it possible to set the output when there are multiple monitoring variables.

The following table is an overview of the monitoring functions that can be assigned to the monitoring output.

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Error notification |
|---------|-----------------------------|-------|------------------------|
| 0 | Overvoltage (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 1 | Undervoltage (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 2 | Overfrequency | 0 | Do not assign function |
| | | 1 | Assign function |
| 3 | Underfrequency | 0 | Do not assign function |
| | | 1 | Assign function |
| 4 | Voltage asymmetry | 0 | Do not assign function |
| | | 1 | Assign function |
| 5 | Phase shift - 1-/3-phase | 0 | Do not assign function |
| | | 1 | Assign function |
| 6 | Df/dt exceeded | 0 | Do not assign function |
| | | 1 | Assign function |
| 7 | Undervoltage 2 (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 8 | Overvoltage 2 (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 9 | Underfrequency 2 | 0 | Do not assign function |
| | | 1 | Assign function |
| 10 | Overfrequency 2 | 0 | Do not assign function |
| | | 1 | Assign function |
| 11 | Microgrid monitoring | 0 | Do not assign function |
| | | 1 | Assign function |
| 12 - 15 | Reserved | - | |

Information:

The minimum pulse duration when a monitoring function responds to both the fault bit via X2X as well as on the output is 500 ms.

9.26.4.20.3.7 Busbar

Busbar nominal voltage (U_{NomBus})

Name:

ConfigOutput03

ConfigOutput03Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------------|------------|
| UINT | 70 to 65000 | For 70 to 65000 V | 1 V |

Multiplier for busbar

Name:

ConfigOutput05

ConfigOutput05Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 thus means a multiplier factor of 1 (measured value not changed).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|--------------------|------------|
| UINT | 1 to 65535 | For 0.01 to 655.35 | 0.01 |

Minimum busbar voltage (U_{Bmin})

Name:

ConfigOutput40

ConfigOutput40Read

Configurable threshold for zero voltage monitoring of the busbar based on its nominal voltage. DO3 is set if the value falls below the configured threshold.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--------------------------------------|------------|
| UINT | 0 to 1000 | For 0 to 100% of U_{NomBus} | 0.1% |

9.26.4.20.3.8 Synchronization

Synchronization mode

Name:

ConfigOutputPacked01

ConfigOutput17 to ConfigOutput19

If multiple mode bits are set at the same time, then no mode will be selected (type BOOL).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------|-------|----------------------|
| 0 | ConfigOutput17 | 0 | Sync mode ≠ Slip |
| | | 1 | Sync mode = Slip |
| 1 | ConfigOutput18 | 0 | Sync mode ≠ Check |
| | | 1 | Sync mode = Check |
| 2 | ConfigOutput19 | 0 | Sync mode ≠ Dead bus |
| | | 1 | Sync Mode = Dead bus |
| 3 - 7 | Reserved | - | |

Synchronization configuration

Name:

ConfigOutput56

ConfigOutput56Read

This register contains parameters for configuring which mains or voltages should be synchronized with each other.

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 - 1 | Synchronization configuration (synchronization mains - mains being synchronized) | 00 | X4 - X6: Synchronization mains 1 - Synchronization mains 2 The configuration X4 - X6 is only possible if "Sync mains 1 / Sync mains 2" is configured in the "ConfigOutput68" on page 2950 register. |
| | | 01 | X4 - X5: Synchronization mains 1 - Busbar |
| | | 10 | X4 - X3: Synchronization mains 1 - Generator |
| | | 11 | X5 - X3: Busbar - Generator |
| 2 - 7 | Reserved | 0 | |
| 8 | Synchronization output | 0 | Digital output 4 |
| | | 1 | Digital output 6 - Output must be configured as a synchronization output (see register "ConfigOutput24" on page 2951) |
| 9 - 15 | Reserved | 0 | |

Max. differential frequency (df_{max})

Name:

ConfigOutput11

ConfigOutput11Read

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded. This value specifies the upper frequency (positive value corresponds to positive slip → generator frequency is greater than the busbar frequency when synchronizing).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|---------|---------------------|------------|
| UINT | 2 to 49 | For 0.02 to 0.49 Hz | 0.01 Hz |

Min. differential frequency (df_{min})

Name:

ConfigOutput12

ConfigOutput12Read

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded in the negative direction. This value specifies the lower frequency (negative value corresponds to negative slip → generator frequency is less than the busbar frequency when synchronizing).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-------------------|------------|
| INT | -49 to 0 | For -0.49 to 0 Hz | 0.01 Hz |

Max. differential voltage (dU_{max})

Name:

ConfigOutput13

ConfigOutput13Read

A switch-on command on DO4 is only output if this configured differential voltage percentage based on the synchronization mains' nominal voltage is not exceeded.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------------------------|------------|
| UINT | 1 to 300 | For 0.1 to 30% of U_{NomSyn} | 0.1% |

Max. permitted differential angle (ϕ_{Max})

Name:

ConfigOutput14

ConfigOutput14Read

A switch-on command on DO4 is only output if the configured differential angle between the two synchronization mains is not exceeded.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|----------------|------------|
| UINT | 1 to 600 | For 0.1 to 60° | 0.1° |

Phase rotation of sync mains 1 (α)

Name:

ConfigOutput15

ConfigOutput15Read

This parameter is used for correcting any phase shifting from upstream transformer vector groups before reaching the mains being synchronized.

This parameter specifies how many degrees the synchronization mains lags behind the mains being synchronized.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|---------------|------------|
| UINT | 0 to 3600 | For 0 to 360° | 0.1° |

Pulse duration of the switch-on relay

Name:

ConfigOutput47 (DO4)

ConfigOutput95 (DO6)

ConfigOutput47Read (DO4)

ConfigOutput95Read (DO6)

The duration of the switch-on pulse can be adjusted for the following switching units.

The value of this register can be read back.

| Data type | Values | Information | Resolution |
|-----------|------------|-----------------|------------|
| UINT | 40 to 1000 | For 0.04 to 1 s | 0.001 s |

Switching response time of the power switch

Name:

ConfigOutput48 (DO4)

ConfigOutput96 (DO6)

ConfigOutput48Read (DO4)

ConfigOutput96Read (DO6)

The actuation time of the generator power switch corresponds to the lead time of the switch-on command. The switch-on command is executed before the point of synchronization according to the amount of time defined here.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-------------------|------------|
| UINT | 40 to 300 | For 0.04 to 0.3 s | 0.001 s |

Dead bus voltage ($U_{BminSync}$)

Name:

ConfigOutput58

ConfigOutput58Read

Configurable threshold for dead bus synchronization based on the nominal voltage of the busbar.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-------------------------------|------------|
| UINT | 0 to 1000 | For 0 to 100% of U_{NomBus} | 0.1% |

2-phase synchronization for commissioning tests

Name:

ConfigOutput93

ConfigOutput93Read

2-phase synchronization for commissioning tests.

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|-------|---|
| 0 | Synchronization | 0 | 3-phase synchronization (normal operation) |
| | | 1 | 2-phase synchronization with L1 and L2 (commissioning tests with 2-phase simulation design) |
| 1 - 7 | Reserved | 0 | |

Information:

It is only possible to set 2-phase synchronization for commissioning tests with a 2-phase simulation design.

If only 2 phases are connected, then the respective mains must be configured with neutral conductors since a network with a "virtual neutral point" is not possible with 2 phases (see register "[ConfigOutput68](#)" on page 2950).

9.26.4.20.3.9 Maximum value buffer and power meter

Pulse value of energy meter output

Name:

ConfigOutput46

ConfigOutput46Read

Output DO2 outputs pulses that occur at a frequency proportional to the measured energy. The frequency of the pulses can be specified. The length of the pulse is 400 ms. The frequency at which the pulses occur should be set so that the duration between two pulses does not exceed 400 ms at the highest possible power. The pulse output's internal meter starts at 0 kWh after a restart. This register has no effect on the "ConfigOutput54" on page 2982 and "ConfigOutput55" on page 2982 registers.

When set to 0, meter output is disabled.

Depending on how the "Power measurement mode" parameter is set in the "ConfigOutput21" on page 2953 register, either the total active power or the active power of the fundamental wave is added together. Changing the parameter "Power measurement mode" during runtime does not cause the internal energy meter to restart.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|--------------------------|-------------|
| UINT | 0 to 65535 | For 0 to 65535 kWh/pulse | 1 kWh/pulse |

Count value for active energy meter and reactive energy meter

Name:

ConfigOutput94

ConfigOutput94Read

This parameter is used to configure the resolution of active and reactive energy counters.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 1 kWh |

Maximum value buffer and meter buffer

These registers are used for nonvolatile storage of the maximum value and meter level values. After restarting, the stored maximum values and meter states are loaded back into their registers and the module's internal work meter is reset. It is possible to reset or write to the stored maximum values and meter states using an acyclic register.

The maximum values are recorded by the effective measured values before reaching the configurable filter. The maximum values can be read or written to as acyclic registers.

Maximum phase current

Name:

Reading: ConfigOutput49 (generator I1)

Reading: ConfigOutput50 (generator I2)

Reading: ConfigOutput51 (generator I3)

Writing: ConfigOutput60 (generator I1)

Writing: ConfigOutput61 (generator I2)

Writing: ConfigOutput62 (generator I3)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Maximum total active power (supplied power)

Name:

Reading: ConfigOutput52

Writing: ConfigOutput63

Depending on the status of the "Power measurement mode" parameter in the "ConfigOutput21" on page 2953 register, either the total power or the fundamental power is added together or compared.

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 kW |

Maximum neutral conductor current

Name:

Reading: ConfigOutput53

Writing: ConfigOutput64

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Active energy counter

Name:

Reading: ConfigOutput54 (delivered (producing))

Reading: ConfigOutput71 (drawn (consuming))

Writing: ConfigOutput66 (delivered (producing))

Writing: ConfigOutput69 (drawn (consuming))

Depending on the status of the "Power measurement mode" parameter in the "ConfigOutput21" on page 2953 register, either the total power or the fundamental power is added together or compared.

The resolution can be configured (see register "ConfigOutput94" on page 2981).

| Data type | Value | Information | Resolution |
|-----------|------------------------------------|-------------|------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | - | Default: 100 kWh |

Reactive energy counter

Name:

Reading: ConfigOutput55 (reactive energy meter delivered (producing))

Reading: ConfigOutput72 (reactive energy meter drawn (consuming))

Writing: ConfigOutput67 (reactive energy meter delivered (producing))

Writing: ConfigOutput70 (reactive energy meter drawn (consuming))

Depending on the status of the "Power measurement mode" parameter in the "ConfigOutput21" on page 2953 register, either the total power or the fundamental power is added together or compared.

The resolution can be configured (see register "ConfigOutput94" on page 2981).

| Data type | Value | Information | Resolution |
|-----------|------------------------------------|-------------|--------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | - | Default: 100 kvarh |

9.26.4.20.4 Communication registers

9.26.4.20.4.1 General registers

DigitalOutputPacked01

Name:

DigitalOutputPacked01

DigitalOutput05

DigitalOutput06

ResetGeneratorErrors

ResetMainsErrors

InvertDO5

The module's default configuration is that the generator and mains error bits are reset by the module. If this should be done by the user, then the module needs to be configured accordingly using the following registers.

- Generator error: "[ConfigOutput21](#)" on page 2953
- Network error: "[ConfigOutput22](#)" on page 2965

(data point applied as BOOL)

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------------|-------|--|
| 0 | DigitalOutput05 | 0 | Reset output 5 |
| | | 1 | Set output 5 |
| 1 | DigitalOutput06 | 0 | Reset output 6 |
| | | 1 | Set output 6 |
| 2 | ResetGeneratorErrors | 0 | Does not reset generator error bits |
| | | 1 | Resets generator error bits |
| 3 | ResetMainsErrors | 0 | Do not reset mains error bits |
| | | 1 | Reset mains error bits |
| 4 | InvertDO5 | 0 | Do not invert Output 5 |
| | | 1 | Invert output 5 of the mains monitoring function |
| 5 - 7 | Reserved | 0 | |

StatusDigitalOutputPacked01

Name:

StatusDigitalOutputPacked01

StatusDigitalOutput01 to StatusDigitalOutput06

StatusInput16 to StatusInput17

(data point applied as BOOL)

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------------|-------|--|
| 0 | StatusDigitalOutput01 | 0 | Current state of output 1 = LOW |
| | | 1 | Current state of output 1 = HIGH |
| ... | | ... | |
| 5 | StatusDigitalOutput06 | 0 | Current state of output 6 = LOW |
| | | 1 | Current state of output 6 = HIGH |
| 6 | StatusInput17 | 0 | Status DO OK |
| | | 1 | Status DO overload |
| 7 | StatusInput16 | 0 | Status 24 V output supply OK |
| | | 1 | Status 24 V output supply undervoltage |

StatusInputPacked01

Name:

StatusInputPacked01

StatusInput01 to StatusInput11

StatusInput31 to StatusInput32

StatusInput18

This register is the error register for the generator mains (error bits are of type BOOL). With regard to bits 9, 11 and 12, please also observe the description of the "Power measurement mode" parameter in the register "[ConfigOutput21](#)" on page 2953.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|---------------|-------|--|
| 0 | StatusInput01 | 0 | Overvoltage (one phase), OK |
| | | 1 | Overvoltage (one phase), present |
| 1 | StatusInput02 | 0 | Undervoltage (one phase), OK |
| | | 1 | Undervoltage (one phase), present |
| 2 | StatusInput03 | 0 | Over-frequency, OK |
| | | 1 | Over-frequency, present |
| 3 | StatusInput04 | 0 | Under-frequency, OK |
| | | 1 | Under-frequency, present |
| 4 | StatusInput05 | 0 | Voltage asymmetry, OK |
| | | 1 | Voltage asymmetry, present |
| 5 | StatusInput06 | 0 | Current asymmetry, OK |
| | | 1 | Current asymmetry, present |
| 6 | StatusInput07 | 0 | Maximum neutral conductor current, OK |
| | | 1 | Maximum neutral conductor current exceeded |
| 7 | StatusInput08 | 0 | Short circuit-current, OK |
| | | 1 | Short circuit-current, present |
| 8 | StatusInput09 | 0 | Rating-dependent overcurrent OK |
| | | 1 | Rating-dependent overcurrent occurring |
| 9 | StatusInput10 | 0 | Capacitive reactive power (exciter failure), OK |
| | | 1 | Capacitive reactive power (exciter failure), present |
| 10 | StatusInput11 | 0 | Ready, OK |
| | | 1 | Not ready |
| 11 | StatusInput31 | 0 | No generator overload |
| | | 1 | Generator overload |
| 12 | StatusInput32 | 0 | No generator feedback |
| | | 1 | Generator feedback |
| 13 - 14 | Reserved | - | |
| 15 | StatusInput18 | 0 | Undervoltage 2 (of a phase) OK |
| | | 1 | Undervoltage 2 (of a phase) occurring |

StatusInput11

The error message "Not ready" is triggered if the X20 I/O supply drops below 18 VDC.

StatusInputPacked02

Name:

StatusInputPacked02

StatusInput24 to StatusInput30

StatusInput33

This register is the error register for the mains (error bits are of type BOOL).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|---------------|-------|---------------------------------------|
| 0 | StatusInput24 | 0 | Overvoltage (one phase), OK |
| | | 1 | Overvoltage (one phase), present |
| 1 | StatusInput25 | 0 | Undervoltage (one phase), OK |
| | | 1 | Undervoltage (one phase), present |
| 2 | StatusInput26 | 0 | Over-frequency, OK |
| | | 1 | Over-frequency, present |
| 3 | StatusInput27 | 0 | Under-frequency, OK |
| | | 1 | Under-frequency, present |
| 4 | StatusInput28 | 0 | Voltage asymmetry, OK |
| | | 1 | Voltage asymmetry, present |
| 5 | StatusInput29 | 0 | Phase shift monitoring OK |
| | | 1 | Phase shift error (1/3 of a phase) |
| 6 | StatusInput30 | 0 | Df/dt OK |
| | | 1 | Df/dt error |
| 7 | StatusInput33 | 0 | Undervoltage 2 (of a phase) OK |
| | | 1 | Undervoltage 2 (of a phase) occurring |

StatusInput33

The data point is only valid if 2-point mode is configured (see register "[ConfigOutput22](#)" on page 2965). This bit only appears in the I/O mapping in Automation Studio if the corresponding status information is enabled in the I/O configuration ("Mains configuration / Additional status information" menu option).

StatusInputPacked03

Name:

StatusInputPacked03

StatusInput12 to StatusInput15

StatusInput19 to StatusInput23

This register is the error register for general error messages (error bits are of type BOOL).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------|-------|--|
| 0 | StatusInput12 | 0 | All phases of the generator mains OK |
| | | 1 | Failure of at least one phase of the generator mains |
| 1 | StatusInput13 | 0 | All phases of the busbar OK |
| | | 1 | Failure of at least one phase of the busbar |
| 2 | StatusInput14 | 0 | All phases of Sync Mains 1 OK |
| | | 1 | Failure of at least one phase of Sync Mains 1 |
| 3 | StatusInput15 | 0 | All phases of Sync Mains 2 OK |
| | | 1 | Failure of at least one phase of Sync Mains 2 |
| 4 | StatusInput19 | 0 | Phase sequence of generator voltage OK |
| | | 1 | Phase sequence of generator voltage incorrect |
| 5 | StatusInput20 | 0 | Phase sequence of generator current OK |
| | | 1 | Phase sequence of generator current incorrect |
| 6 | StatusInput21 | 0 | Phase sequence of busbar OK |
| | | 1 | Phase sequence of busbar incorrect |
| 7 | StatusInput22 | 0 | Phase sequence of Sync Mains 1 OK |
| | | 1 | Phase sequence of Sync Mains 1 incorrect |
| 8 | StatusInput23 | 0 | Phase sequence of Sync Mains 2 OK |
| | | 1 | Phase sequence of Sync Mains 2 incorrect |
| 9 - 15 | Reserved | - | |

StatusInput12 to StatusInput15: Phase failure is detected if at least one of the phases of the respective terminal fails.

StatusInput19 to StatusInput23 are status bits for detecting a change of rotation.

StatusInputPacked04

Name:

StatusInputPacked04

StatusInput34 to StatusInput37

This register is the error register for the mains (error bits are of type BOOL). These bits only appear in the I/O mapping in Automation Studio if the corresponding status information is enabled in the I/O configuration ("Mains configuration / Additional status information" menu option).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------|-------|--------------------------------------|
| 0 | StatusInput34 | 0 | Overvoltage 2 (of a phase) OK |
| | | 1 | Overvoltage 2 (of a phase) occurring |
| 1 | StatusInput35 | 0 | Underfrequency 2 OK |
| | | 1 | Underfrequency 2 occurring |
| 2 | StatusInput36 | 0 | Overfrequency 2 OK |
| | | 1 | Overfrequency 2 occurring |
| 3 | StatusInput37 | 0 | Microgrid monitoring OK |
| | | 1 | Microgrid monitoring tripped |
| 4 - 15 | Reserved | - | |

StatusInputPacked05

Name:

StatusInputPacked05

StatusInput38 to StatusInput40

This register is the error register for the generator mains (error bits are of type BOOL). These bits only appear in the I/O mapping in Automation Studio if the corresponding status information is enabled in the I/O configuration ("Generator mains / Additional status information" menu option).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------|-------|--------------------------------------|
| 0 | StatusInput38 | 0 | Overvoltage 2 (of a phase) OK |
| | | 1 | Overvoltage 2 (of a phase) occurring |
| 1 | StatusInput39 | 0 | Underfrequency 2 OK |
| | | 1 | Underfrequency 2 occurring |
| 2 | StatusInput40 | 0 | Overfrequency 2 OK |
| | | 1 | Overfrequency 2 occurring |
| 3 - 15 | Reserved | - | |

9.26.4.20.4.2 Generator mains measured values**Phase currents of the generator**

Name:

AnalogInput01 (I1)

AnalogInput02 (I2)

AnalogInput03 (I3)

Phase currents of the generator

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Neutral conductor current of generator I_n

Name:

AnalogInput05

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Current average of generator I1, I2, I3

Name:

AnalogInput04

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Dynamic current average of generator (I_{m_dyn})

Name:

AnalogInput06

Describes the change to the current average.

The dynamic average is the amount of change (I_{m_diff}) of the current average (sampling time: 10 ms).

This value decays in an e-function.

$$I_{m_diff} > I_{m_dyn} \rightarrow I_{m_dyn} = I_{m_diff}$$

$$I_{m_diff} \leq I_{m_dyn} \rightarrow I_{m_dyn} = I_{m_dyn} * 0.98$$

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 1 A |

Line-to-line voltages of the generator

Name:

AnalogInput07 (UG12)

AnalogInput08 (UG23)

AnalogInput09 (UG31)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Phase voltages of the generator

Name:

AnalogInput10 (UG 1)

AnalogInput11 (UG 2)

AnalogInput12 (UG 3)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Voltage average of the generator

Name:

AnalogInput22

Voltage average of the generator UG12, UG23, UG31 (U~3 average)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Filtered generator power values:

Name:

AnalogInput19

AnalogInput20

AnalogInput21

Filtered generator power values:

- Total output (sum of all harmonic frequencies)
- Fundamental frequency power (_H1)

Configuration is explained in the "[ConfigOutput21](#)" on page 2953 register.

| Data type | Value | Information | Resolution |
|-----------|-----------------|-----------------------------|------------|
| INT | -32768 to 32767 | Total active power P/P_H1 | 1 kW |
| | -32768 to 32767 | Total reactive power Q/Q_H1 | 1 kvar |
| | -32768 to 32767 | Total apparent power S/S_H1 | 1 kVA |

Power factor of generator/cos ϕ

Name:

AnalogInput23

The factor is described in "[Power factor of the generator](#)" on page 2941 and register "[ConfigOutput21](#)" on page 2953.

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 0.001 |

Frequency of the generator mains

Name:

AnalogInput24

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

Timestamp for generator voltages and currents

These timestamps mark the last positive zero crossing of the generator voltages (L1-N, L2-N, L3-N) and generator currents (I1, I2, I3). They can be used to calculate all the necessary phase ratios.

Calculation of the phase ratios and error handling for the calculations are to be implemented by the user (e.g. period duration monitoring or verification that the voltages are high enough, etc.).

These timestamps only appear in the I/O mapping in Automation Studio if they are enabled in the I/O configuration ("Enable timestamps for generator voltage and current" menu option).

Timestamp of pos. zero crossing of phase voltage

Name:

AnalogInput38 (UG1)

AnalogInput39 (UG2)

AnalogInput40 (UG3)

Time stamp of pos. zero crossing of phase voltage of the respective generator

| Data type | Value | Information | Resolution |
|-----------|------------------------------------|-------------|------------|
| DINT | -2,147,483,648 to 2,147,483,647 | - | 1/4096 µs |

Timestamp of pos. zero crossing of phase current

Name:

AnalogInput41 (I1)

AnalogInput42 (I2)

AnalogInput43 (I3)

Time stamp of pos. zero crossing of phase current of the respective generator

| Data type | Value | Information | Resolution |
|-----------|------------------------------------|-------------|------------|
| DINT | -2,147,483,648 to 2,147,483,647 | - | 1/4096 µs |

9.26.4.20.4.3 Busbar measured values**Line-to-line voltages of the busbar**

Name:

AnalogInput13 (UB12)

AnalogInput14 (UB23)

AnalogInput15 (UB31)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|

AnalogInput35

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

9.26.4.20.4.4 Measured value of synchronization mains

(for mains configuration "Sync mains 1 / Sync mains 2")

Line-to-line voltages

Name:

AnalogInput25 (sync mains 1 US1)

AnalogInput26 (sync mains 2 US2)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Frequencies

Name:

AnalogInput27 (sync mains 1)

AnalogInput28 (sync mains 2)

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

9.26.4.20.4.5 Measured value of mains

(for "3-phase mains" configuration)

Line-to-line voltages of mains

Name:

AnalogInput25 (UN12)

AnalogInput31 (UN23)

AnalogInput32 (UN31)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Phase voltages of the generator

Name:

AnalogInput33 (UN1)

AnalogInput34 (UN2)

AnalogInput26 (UN3)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Frequency of power mains

Name:

AnalogInput27

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

9.26.4.20.4.6 Generator monitoring**Read unbalanced load meter**

Name:

AnalogInput36

This register can be used to track the current state of the unbalanced load meter (see "[Dependent delayed unbalanced load monitoring](#)" on page 2957). The unbalanced load meter can be reset with an acyclic trigger bit (see register "[ConfigOutput23](#)" on page 2952).

| Data type | Value | Information | Resolution |
|-----------|------------|---------------|------------|
| UINT | 0 to 65535 | For 0 to 100% | |

Reads the unbalanced load current (I₂)

Name:

AnalogInput37

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

9.26.4.20.4.7 Synchronization**Differential angle between synchronization mains**

Name:

AnalogInput29

Angular difference between the mains being synchronized

Specifies how many degrees the sync mains are ahead of the mains being synchronized.

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 0.1° |

Differential voltage between synchronization mains

Name:

AnalogInput30

Voltage difference between the mains being synchronized

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

9.26.4.20.5 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 250 μ s |

9.26.4.20.6 Minimum I/O update time

The minimum I/O update time for the analog inputs depends on the respective period duration of the measurement signal frequency.

| Minimum I/O update time |
|-------------------------|
| At 50 Hz 10 ms |

9.26.5 X20CM4323

Data sheet version: 1.10

9.26.5.1 General information

The module has digital outputs for connecting electromechanical loads (e.g. valves and relays) and additional functions such as edge generation.

With a resolution down to 125 ns, the module makes it possible to set switching operations at exactly specified moments.

The following operating modes can optionally be supplemented with PWM functionality:

- Direct I/O
- Oversampled I/O
- Edge generator
- Edge generator in toggle operation for output patterns such as digital cam switches (e.g. digital cam switch of function block "ASMcDcsTimedDigitalCamSwitch")

Additional functions:

- PWM modulation of outputs for setting the overexcitation and holding current.
- Configuration of each channel by specifying PWM period duration
- Control value for overexcitation current, holding current and overexcitation time
- Possibility of disabling high-speed cutoff

Features:

- 4 digital outputs
- Control of PWM output signals based exactly on NetTime
- 4x oversampling output functions
- Integrated output protection
- 24 VDC and GND for actuator power supply

9.26.5.2 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | Other functions |  |
| X20CM4323 | X20 PWM module, 4 digital outputs for switching electro-mechanical loads, 24 VDC, oversampling output functions, time-triggered output functions, NetTime function | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |

Table 538: X20CM4323 - Technical data

9.26.5.4 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|--------------------------------|--------------|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered. |
| | e + r | Solid red / Single green flash | | Invalid firmware |
| | 1 - 4 | Orange | On/Off | Status of the digital outputs |
| | | | Blinking | Short circuit / overcurrent cutoff |

Information:

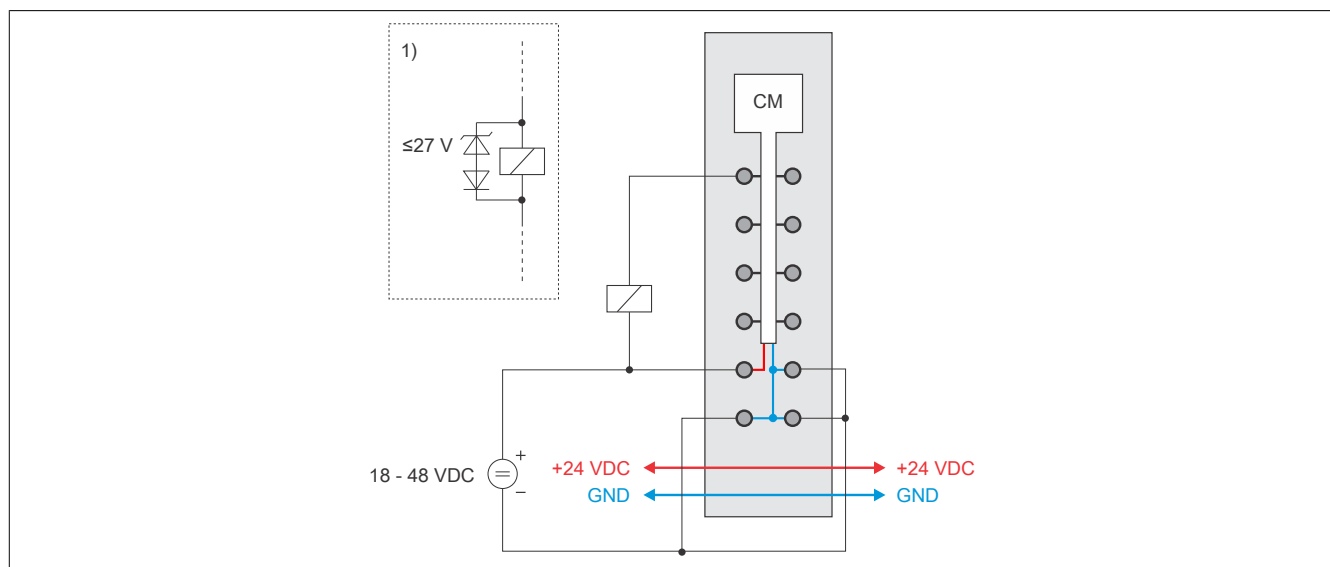

The output is not automatically activated after an overcurrent cutoff. It must be switched on again.

1) Depending on the configuration, a firmware update can take up to several minutes.

9.26.5.5 Pinout

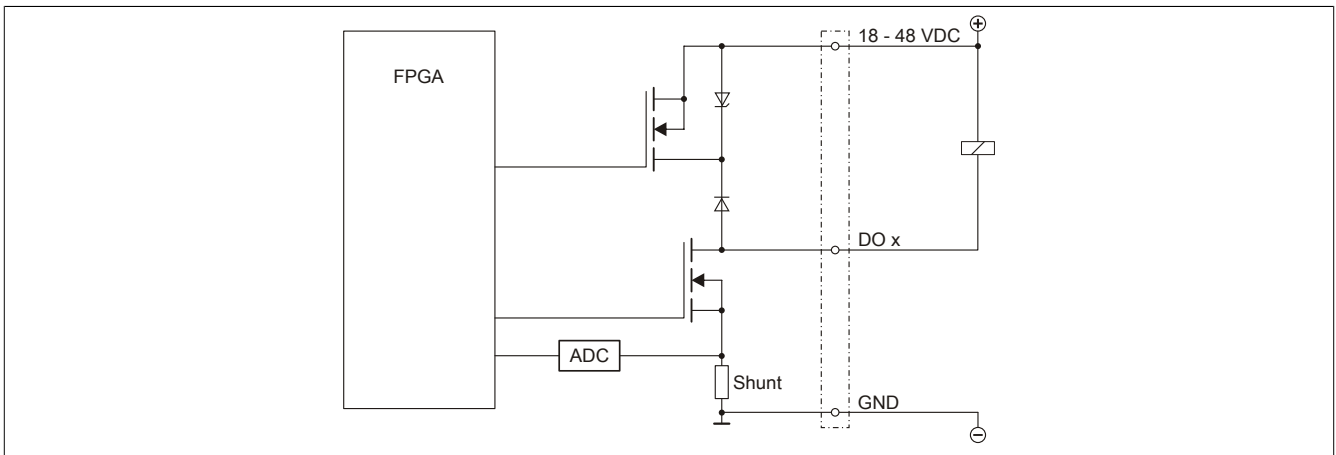

9.26.5.6 Connection example

1) If larger inductances or more current are used; the "transil-diode combination" must be placed externally on the relay/valve.

9.26.5.7 Output circuit diagram

9.26.5.8 Switching inductive loads

In principle, the inductance that is connected is limited by the maximum power dissipation of the module.

If larger inductances or more current are used, the "transil-diode combination" must be placed externally on the relay/valve (see ["Connection example" on page 2994](#)).

Information:

The inductance of a relay/valve depends greatly on the core material being used. Therefore, an inductance must be used that corresponds to the diagram at 1Hz. This information can be found in the data sheet of the connected inductance (relay/valve).

9.26.5.9 Register description

9.26.5.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.26.5.9.3 General

9.26.5.9.3.1 Use with Automation Studio

The module is only supported by SG4 target systems via X2X and POWERLINK!

X2X Link supports the following synchronous cyclic data per module:

- 31 bytes input data consisting of 30 input bytes and X2X status byte
- 30 bytes output data

To optimize use and prevent needless data transfer, data points can be adjusted as needed in Automation Studio. Unnecessary data points can be disabled, and the bit width of the data points can be defined.

9.26.5.9.3.2 Timestamp function

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

Conversely, the CPU can predefine output events, apply a timestamp and transfer them to the module. The module then executes the predefined action at the precise moment defined by the CPU.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

The resolution of the timestamp is up to 1/8 μ s in both directions.

Synchronization jitter

Because the CPU – which specifies the X2X NetTime – and the module have different clocks, the module's internal X2X NetTime must be synchronized with the CPU's NetTime. Due to this synchronization, the module's internal X2X NetTime is corrected by a maximum of 1/8 μ s per system cycle if necessary. This synchronization jitter becomes noticeable when using the NetTime with 1/8 μ s resolution (max. \pm 1/8 μ s).

If a 100% exact 1/8 μ s resolution without jitter is required, then "Local time 1/8 μ s" must be used (see register "[CfO_EdgeGenUnitMode](#)" on page 3016).

9.26.5.9.4 General registers

9.26.5.9.4.1 Defining the moment for generating synchronous input data

Name:

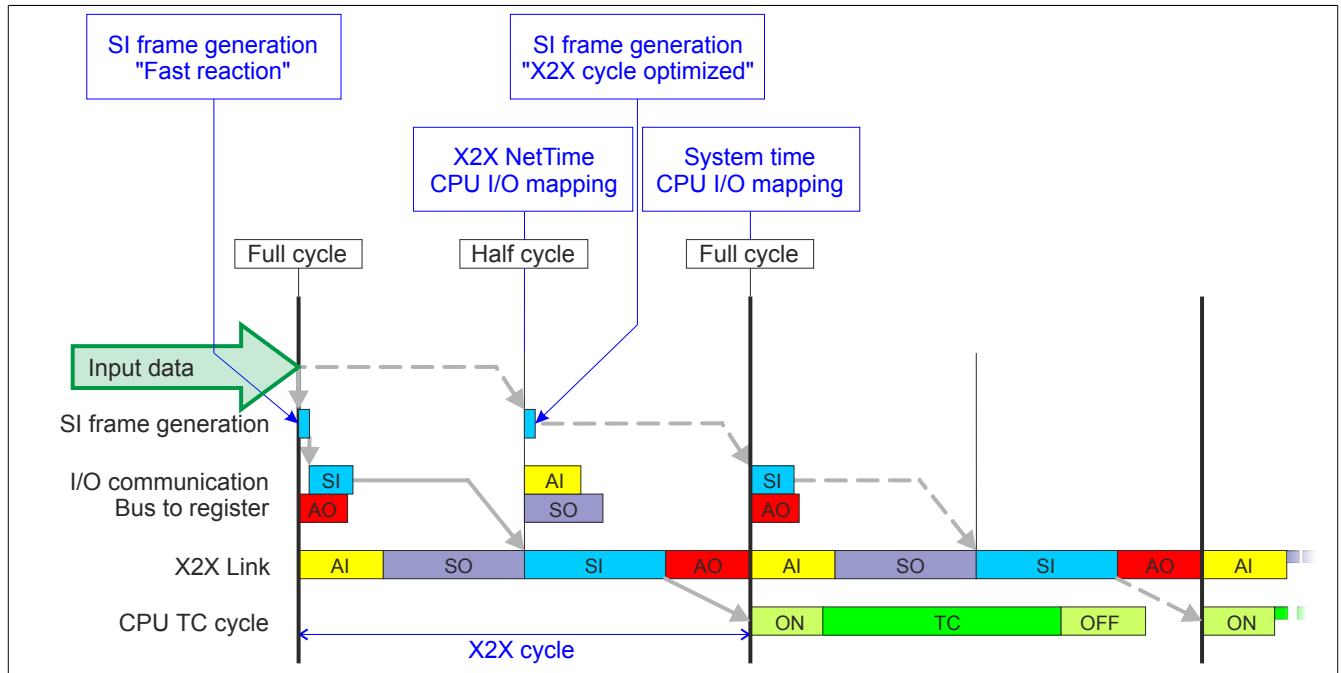

CfO_SlframeGenID

"SI frame generation" in the Automation Studio I/O configuration.

When the synchronous input data is generated for transfer is defined in this register. This has a decisive effect on the timing of the input data.

Setting "Fast reaction" causes the input data to be available one X2X cycle sooner in the CPU. However, this setting also has a negative effect on the minimum X2X cycle time.

| Data type | Values | Information |
|-----------|--------|---------------------|
| USINT | 9 | X2X cycle optimized |
| | 14 | Fast reaction |

9.26.5.9.4.2 Number of X2X protocol errors

Name:

ProtocolError

This register contains an error counter that specifies the number of X2X protocol errors. In the I/O configuration, parameter "Network information" can be used to help configure a data point for this register with a bit width of 8 or 16 bits in the I/O mapping.

| Data type | Values | Information |
|-----------|------------|------------------------|
| USINT | 0 to 255 | Error counter (8-bit) |
| UINT | 0 to 65535 | Error counter (16-bit) |

9.26.5.9.4.3 Number of X2X sequence violations

Name:

ProtocolSequenceViolation

This register contains an error counter that specifies the number of X2X sequence violations. In the I/O configuration, parameter "Network information" can be used to help configure a data point with a bit width of 8 or 16 bits in the I/O mapping.

| Data type | Values | Information |
|-----------|------------|------------------------|
| USINT | 0 to 255 | Error counter (8-bit) |
| UINT | 0 to 65535 | Error counter (16-bit) |

9.26.5.9.4.4 System clock counter for checking the validity of the data frame

Name:

SDCLifeCount

Counter that is incremented with each system timer cycle. "SDC information" in the Automation Studio I/O configuration can be used to enable this register in the I/O mapping as data point "SDCLifeCount".

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

9.26.5.9.5 Error handling

If one of the functions detects an error, then an error bit is set in one of the error state registers. The application is now able to react accordingly and acknowledge the errors by setting a respective bit in the "Acknowledge error message" registers. This causes the bit to be reset in the error state register. If the source of the error persists, then the error bit is set again as soon as the error is detected again (i.e. cannot be reset).

After the error source has been corrected and the error acknowledged, the module must be re-enabled by disabling and re-enabling the enable registers in order to resume processing. The following registers are affected:

- Oversampling configuration: Register "[OversampleEnable](#)" on page 3010
- Edge generation - Enabling units: Register "[EdgeGenEnable](#)" on page 3018
- Enabling the PWM function: Register "[DigitalOutputEnable](#)" on page 3005

If an error occurs (not a warning), this is indicated by the red "e" LED on the module (double flash). This signal is automatically acknowledged as soon as the source of the error has been corrected.

9.26.5.9.5.1 Error status - Output data

Name:

OutputControlError

OutputCopyError

This register indicates data output errors.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------|-------|--|
| 0 - 3 | Reserved | - | |
| 4 | OutputControlError | 0 | No error |
| | | 1 | The module did not receive new data in time while in the mode "Output control mode = single", meaning that a bit that has already been output would have been output again by the output control buffer. |
| 5 | OutputCopyError | 0 | No error |
| | | 1 | Oversampling output data could not be copied to the output control buffer (attempted to write to an address outside the oversampling output window , for example). |
| 6 - 7 | Reserved | - | |

9.26.5.9.5.2 Error messages - Edge generator

Name:

EdgeGen01Error to EdgeGen04Error

EdgeGen01Warning to EdgeGen04Warning

This register indicates edge detection errors.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|------------------|-------|------------------------------|
| 0 | EdgeGen01Error | 0 | No error |
| | | 1 | Unit 1 error ¹⁾ |
| 1 | EdgeGen01Warning | 0 | No error |
| | | 1 | Unit 1 warning ²⁾ |
| 2 | EdgeGen02Error | 0 | No error |
| | | 1 | Unit 2 error ¹⁾ |
| 3 | EdgeGen02Warning | 0 | No error |
| | | 1 | Unit 2 warning ²⁾ |
| 4 | EdgeGen03Error | 0 | No error |
| | | 1 | Unit 3 error ¹⁾ |
| 5 | EdgeGen03Warning | 0 | No error |
| | | 1 | Unit 3 warning ²⁾ |
| 6 | EdgeGen04Error | 0 | No error |
| | | 1 | Unit 4 error ¹⁾ |
| 7 | EdgeGen04Warning | 0 | No error |
| | | 1 | Unit 4 warning ²⁾ |

1) Possible errors

- Due to "EdgeGenPollCycle", one or more timestamps from the edge generator of a unit were not able to be processed in time, and it was not possible to catch back up (see register "CfO_EdgeGenUnitPickupDiff" on page 3017).
- A branched ring-shaped chain of edges in a unit is attempting to set the timestamp for an edge even though the FIFO buffer of the configured physical channel is already full (see register "CfO_EdgeGenUnitConfigEdge" on page 3018 → - Ring-shaped chain of edges).

- 2) Due to "EdgeGenPollCycle", one or more timestamps from the edge generator of a unit were not able to be processed in time, and it was possible to catch back up (see register "CfO_EdgeGenUnitPickupDiff" on page 3017).

9.26.5.9.5.3 Error status - Overcurrent of a PWM output

Name:

DigitalOutput01Err to DigitalOutput04Err

A set bit reports an overcurrent error from the PWM hardware and disables the output until acknowledged by the user.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------|-------|-------------|
| 0 | DigitalOutput01Err | 0 | No change |
| | | 1 | Overcurrent |
| 1 | DigitalOutput02Err | 0 | No change |
| | | 1 | Overcurrent |
| 2 | DigitalOutput03Err | 0 | No change |
| | | 1 | Overcurrent |
| 3 | DigitalOutput04Err | 0 | No change |
| | | 1 | Overcurrent |
| 4 - 7 | Reserved | - | |

9.26.5.9.5.4 Acknowledge error messages - Output data

Name:

QuitOutputControlError

QuitOutputCopyError

Error messages from the "[Error status - Output data](#)" on page 3000 register can be acknowledged by setting the corresponding bits in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|-------|-------------------|
| 0 - 3 | Reserved | - | |
| 4 | QuitOutputControlError | 0 | No change |
| | | 1 | Acknowledge error |
| 5 | QuitOutputCopyError | 0 | No change |
| | | 1 | Acknowledge error |
| 6 - 7 | Reserved | - | |

9.26.5.9.5.5 Acknowledge error messages - Edge generator

Name:

QuitEdgeGen01Error to QuitEdgeGen04Error

QuitEdgeGen01Warning to QuitEdgeGen04Warning

The error message from register "[Error messages - Edge generator](#)" on page 3001 can be acknowledged in this register by setting the respective bit.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|----------------------|-------|---------------------|
| 0 | QuitEdgeGen01Error | 0 | No change |
| | | 1 | Acknowledge error |
| 1 | QuitEdgeGen01Warning | 0 | No change |
| | | 1 | Acknowledge warning |
| 2 | QuitEdgeGen02Error | 0 | No change |
| | | 1 | Acknowledge error |
| 3 | QuitEdgeGen02Warning | 0 | No change |
| | | 1 | Acknowledge warning |
| 4 | QuitEdgeGen03Error | 0 | No change |
| | | 1 | Acknowledge error |
| 5 | QuitEdgeGen03Warning | 0 | No change |
| | | 1 | Acknowledge warning |
| 6 | QuitEdgeGen04Error | 0 | No change |
| | | 1 | Acknowledge error |
| 7 | QuitEdgeGen04Warning | 0 | No change |
| | | 1 | Acknowledge warning |

9.26.5.9.5.6 Acknowledge error messages - Overcurrent of a PWM output

Name:

DigitalOutput01ErrQuit to DigitalOutput04ErrQuit

Error messages from the "[Error status - Overcurrent of a PWM output](#)" on page 3001 register can be acknowledged by setting the corresponding bits in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|-------|----------------------|
| 0 | DigitalOutput01ErrQuit | 0 | No change |
| | | 1 | Acknowledging errors |
| 1 | DigitalOutput02ErrQuit | 0 | No change |
| | | 1 | Acknowledging errors |
| 2 | DigitalOutput03ErrQuit | 0 | No change |
| | | 1 | Acknowledging errors |
| 3 | DigitalOutput04ErrQuit | 0 | No change |
| | | 1 | Acknowledging errors |
| 4 - 7 | Reserved | - | |

9.26.5.9.6 System timer

The module's individual functions all depend on a system timer. This internal "system cycle time" can be defined from 25 to 255 μ s. The functions can also be run with the help of a configurable "prescaled system timer" to minimize the load on the module, thereby making it possible to use the shortest possible X2X cycle time.

The cycle of the "prescaled system timer" (and system timer) is referenced with the X2X Link as soon as the module has been started up and the X2X Link has been initialized. Since the system timer and the module's internal `NetTime` use the same clock, the two run synchronously from that point on. An X2X cycle time that is not a multiple of the system cycle time results in an offset, which can be calculated, however.

The following values apply to the following example:

| | |
|------------------------|-------------|
| X2X cycle | 1 ms |
| System timer | 150 μ s |
| Prescaled system timer | 4 |

9.26.5.9.6.1 Setting the cycle time of the system timer

Name:

`CfO_SystemCycleTime`

"Cycle time" in the Automation Studio I/O configuration.

The cycle time of the system timer can be set in steps of 1/8 μ s in this register. The value entered in the Automation Studio I/O configuration is automatically multiplied by 8.

Information:

A setting <50 μ s has a negative effect on the minimum X2X cycle time!

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 200 to 2047 | System timer cycle time in steps of 1/8 μ s (25 to 255.875 μ s) |

9.26.5.9.6.2 Offsetting the synchronization moment of the system cycle

Name:

`CfO_SystemCycleOffset`

"Cycle offset" in the Automation Studio I/O configuration.

The synchronization moment for the system cycle can be offset in steps of 1/8 μ s in this register. The value entered in the Automation Studio I/O configuration is automatically multiplied by 8.

| Data type | Values | Information |
|-----------|-----------------|--|
| INT | -32768 to 32767 | Cycle offset in steps of 1/8 μ s (-4096 to 4095.875 μ s) |

9.26.5.9.6.3 Configuration of the cycle prescaler

Name:

`CfO_SystemCyclePrescaler`

"Cycle prescaler" in the Automation Studio I/O configuration.

The prescaler for setting the `prescaled system timer` can be configured in this register. The cycle time of the specified system timer is a product of the system timer multiple set in this register.

The "prescaled system timer" can be used as an alternative time source for the individual functions. This is useful if a function requires a very short system cycle. To reduce the load on the module in such a situation, other functions can be processed in a slow cycle.

| Data type | Values | Information |
|-----------|----------|------------------------------|
| UINT | 2 to 128 | Multiple of the system timer |

9.26.5.9.7 Direct I/O

Direct I/O makes it possible to use the physical I/Os like normal I/Os. Additionally, the application can only set or reset I/Os (e.g. an output channel is set by the edge generator and manually reset by the application).

9.26.5.9.7.1 Direct operation of the output channel - Reset

Name:

CfO_DirectIOClearMask0_3

"Direct operation of output channel 01" to "Direct operation of output channel 04" in the Automation Studio I/O configuration.

If the bit for the respective channel is set in this register, then the output is reset as soon as its direct I/O output channel is reset (register "[DigitalOutput0x](#)" on page 3005 in the Automation Studio I/O mapping).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------|-------|---------------|
| 0 | Output channel 1 | 0 | No change |
| | | 1 | Reset channel |
| 1 | Output channel 2 | 0 | No change |
| | | 1 | Reset channel |
| 2 | Output channel 3 | 0 | No change |
| | | 1 | Reset channel |
| 3 | Output channel 4 | 0 | No change |
| | | 1 | Reset channel |
| 4 - 7 | Reserved | - | |

9.26.5.9.7.2 Direct operation of the output channel - Set

Name:

CfO_DirectIOSetMask0_3

"Direct operation of output channel 01" to "Direct operation of output channel 04" in the Automation Studio I/O configuration.

If the bit for the respective channel is set in this register, then the output is set as soon as its direct I/O output channel is set (register "[DigitalOutput0x](#)" on page 3005 in the Automation Studio I/O mapping).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------|-------|-------------|
| 0 | Output channel 1 | 0 | No change |
| | | 1 | Set channel |
| 1 | Output channel 2 | 0 | No change |
| | | 1 | Set channel |
| 2 | Output channel 3 | 0 | No change |
| | | 1 | Set channel |
| 3 | Output channel 4 | 0 | No change |
| | | 1 | Set channel |
| 4 - 7 | Reserved | - | |

9.26.5.9.7.3 Direct operation of the output channel - Moment of data output

Name:

CfO_OutputUpdateCycle

The moment when data is output is set with this register.

| Data type | Values | Information |
|-----------|--------|-----------------------------------|
| USINT | 10 | X2X cycle optimized (jitter-free) |
| | 15 | Fast reaction (with jitter) |

9.26.5.9.7.4 Direct operation of the output channel - Output status

Name:

DigitalOutput01 to DigitalOutput04

This register contains the bits for controlling the direct I/O output channels. Depending on the configuration of registers "CfO_DirectIOClearMask0_3" on page 3004 and "CfO_DirectIOSetMask0_3" on page 3004, the digital outputs are set to the status of the respective bit in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|--------|----------------------------|
| 0 | DigitalOutput01 | 0 or 1 | Output status of channel 1 |
| 1 | DigitalOutput02 | 0 or 1 | Output status of channel 2 |
| 2 | DigitalOutput03 | 0 or 1 | Output status of channel 3 |
| 3 | DigitalOutput04 | 0 or 1 | Output status of channel 4 |
| 4 - 7 | Reserved | - | |

9.26.5.9.7.5 Direct operation of the output channel - Enabling the PWM function

Name:

DigitalOutput01Enable to DigitalOutput04Enable

A set bit enables the PWM function.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------|-------|--------------|
| 0 | Output channel 1 | 0 | PWM disabled |
| | | 1 | PWM enabled |
| 1 | Output channel 2 | 0 | PWM disabled |
| | | 1 | PWM enabled |
| 2 | Output channel 3 | 0 | PWM disabled |
| | | 1 | PWM enabled |
| 3 | Output channel 4 | 0 | PWM disabled |
| | | 1 | PWM enabled |
| 4 - 7 | Reserved | - | |

9.26.5.9.8 Oversampled I/O

"Oversampled I/O" based on output control buffers. Output control occurs in one sample cycle (one sample cycle corresponds to one bit in the buffer).

In "Output control mode = single" every output buffer entry is marked as invalid once it has been executed. This ensures that the outputs are not supplied with invalid data. In this mode, the application needs to ensure that the module is always supplied with valid data.

When using "Output control mode = continuous" the contents of the buffer are output again if the module is not supplied with new oversample output data.

9.26.5.9.8.1 Addressing the output control buffer

The module has one cyclic 256-bit output control buffer for each oversample channel. One bit is output from these buffers to the configured physical output channels in each "sample cycle". When new data is transferred to one of these buffers, the application must define where in the respective buffer the data should be written to. There are 2 possibilities available for this (absolute or relative "Output mode" in the Automation Studio I/O configuration).

9.26.5.9.8.2 Absolute addressing of the output control buffer

With absolute addressing, in each cycle where "OversampleOutputValidate = True", in addition to the oversample output sample data (in the "OversampleOutput0NSample" on page 3011 registers) an address must also be transferred in the "OversampleOutputCycle" on page 3011 register. This address determines where in the output control buffer the new data should be copied to. In order to calculate this address, the contents of register "OversampleInputCycle" on page 3011, which contains the address of the most recently output data, and the transfer time to the module must be taken into consideration. To help avoid incorrect addressing of the output control buffer, the buffer section that is capable of being written to can be limited using register "OversampleOutputWindow" on page 3010. This window will always be shifted relative to the current sample address. An "OutputCopyError" will be triggered if an attempt is made to write to an address that is outside of this window.

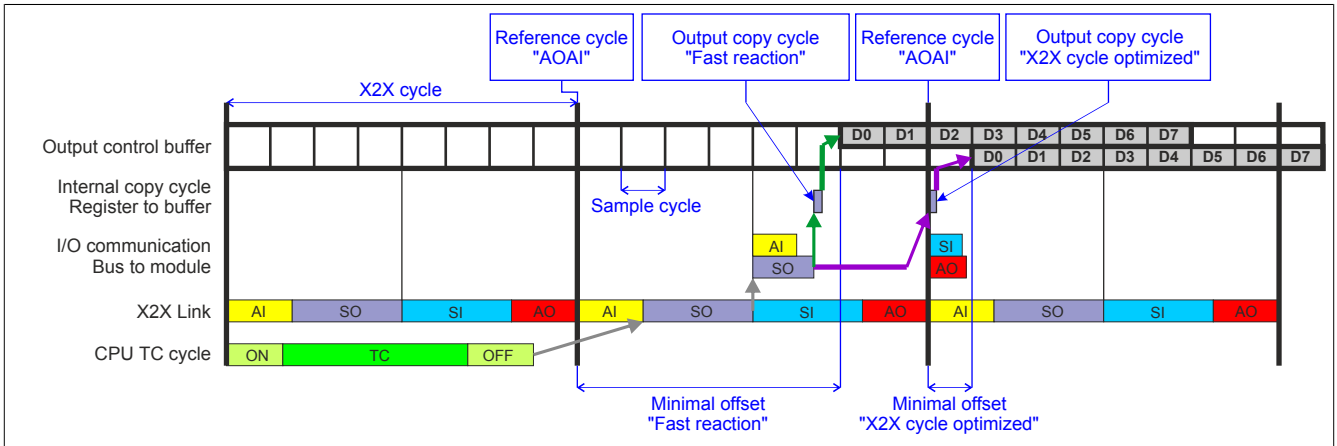

Example

Timing of an oversample output cycle in absolute output mode ("SI frame generation = Fast reaction", "Output copy cycle = Fast reaction", 8 samples per X2X cycle):

9.26.5.9.8.3 Relative addressing of the output control buffer

When "OversampleOutputValidate = True", then the oversample output sample data is automatically copied to an address relative to the last referenced address at the defined **output copy cycle** time. The "OversampleSampleOffset" on page 3011 register serves as the offset. The new data cannot start being output immediately at the **output copy cycle** time because it takes time to copy the data from the registers to the buffer. This means that an offset of 0 is not allowed. The relative output control buffer address + offset must point to an address within the "oversample output window". The **oversample output window** is always offset relative to the current sample address. An **OutputCopyError** is triggered if an attempt is made to write to an address that is outside of this window.

9.26.5.9.8.4 Configuration of the output control buffer

Name:

CfO_OversampleMode

"Output mode" in the Automation Studio I/O configuration

"Output control mode" in the Automation Studio I/O configuration

The output control buffer can be configured globally for all channels in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------------------|-------|---|
| 0 | Addressing the output control buffer | 0 | Absolute addressing of the output control buffer |
| | | 1 | Relative addressing of the output control buffer |
| 1 | Cyclic output control | 0 | Single - Output control buffer entry is marked invalid after execution. |
| | | 1 | Continuous - Output control buffer entry is not changed. |
| 2 - 7 | Reserved | - | |

Cyclic output control

If cyclic output control is enabled, then all data in the output control buffer is marked invalid as soon as it is output ("Output control mode = single"). An [OutputControlError](#) is generated if the module does not receive data in time, thereby causing a situation in which a bit that has already been output would be output in the buffer again. In such a situation, the output assumes the "Output default state" configured in the "[CfO_OversampleConfigOutput](#)" on [page 3010](#) register.

If cyclic output control is disabled, then the data is output again if the output control buffer overflows ("Output control mode = continuous").

Information:

All 256 bits of the output control buffer are always output.

9.26.5.9.8.5 Configuration of the source for the sample cycle

Name:

CfO_OversampleSampleCycleID

"Sample cycle" in the Automation Studio I/O configuration.

The source of the sample cycle can be configured in this register. During each sample cycle, a bit is output from the output control buffers of the oversample I/O channels to the configured physical output.

| Data type | Value | Information |
|-----------|-------|--|
| USINT | 2 | System timer The value configured in the " CfO_SystemCycleTime " on page 3003 register is used as the sample cycle. |
| | 3 | Prescaled system timer The "prescaled system timer" is used as sample cycle. |
| | 10 | AOAI The sample cycle is clocked with the AOAI interrupt of the X2X cycle. |
| | 14 | SOSI The sample cycle is clocked with the SOSI interrupt of the X2X cycle. |

9.26.5.9.8.6 Configuration of the source for the user interface reference cycle

Name:

CfO_OversampleRelativeCycleID

"Reference cycle" in the Automation Studio I/O configuration.

The source of the user interface reference cycle can be configured in this register.

- With relative addressing of the output control buffer, the new sample data is copied to an address relative to the output control buffer address current to the "reference cycle".
- The reference cycle is also used to reference the sample cycle, and with it also the output data production (e.g. to the X2X cycle).

| Data type | Value | Information |
|-----------|-------|---|
| USINT | 2 | System timer The value configured in the "CfO_SystemCycleTime" on page 3003 register is used as the reference cycle. |
| | 3 | Prescaled system timer The prescaled system timer is used as sample cycle. |
| | 10 | AOAI The sample cycle is referenced with the AOAI interrupt of the X2X cycle. |
| | 14 | SOSI The sample cycle is referenced with the SOSI interrupt of the X2X cycle. |

9.26.5.9.8.7 Defining the moment for copying the data to the output control buffer

Name:

CfO_OversampleConsumeCycleID

"Output copy cycle" in the Automation Studio I/O configuration.

At the time of the output copy cycle, data is copied from the "[OversampleOutput0NSample](#)" on page 3011 registers into the output control buffer.

When "Output copy cycle = Fast reaction", it is not possible to determine when the data is copied to the output control buffer in either of the two addressing modes. The copy cycles will experience a certain degree of jitter depending on the module load. However, this only affects the moment of the internal copy procedures and therefore the moment of the earliest possible output sample. This will not affect the quality of the output signal. However, "Output copy cycle = Fast reaction" also has a negative effect on the minimum X2X cycle time.

When using the setting "Output copy cycle = X2X cycle optimized", be aware that the sample data cannot start being output immediately at the "Output copy cycle" time due to the internal copy cycle to the output control buffers.

| Data type | Values | Information |
|-----------|--------|---|
| USINT | 10 | X2X cycle optimized The output data is copied to the output control buffer with the AOAI interrupt of the X2X cycle. |
| | 15 | Fast reaction The output data is copied to the output control buffer immediately after being received. |

9.26.5.9.8.8 Number of output bits to be transferred

Name:

CfO_OversampleOutputBits

"User interface size" in the Automation Studio I/O configuration.

Specifies how many bits are transferred from the "[OversampleOutput0NSample](#)" on page 3011 registers to the output control buffers at the [output copy cycle](#) moment.

| Data type | Values | Information |
|-----------|---------|-------------|
| USINT | 1 to 64 | Output bits |

9.26.5.9.8.9 Write area in the output control buffer

Name:

CfO_OversampleOutputWindow

"Output control mode" in the Automation Studio I/O configuration.

Determines the area in the output control buffer in which data can be written. The window is always offset relative to the current sample position. (a value of 128, for example, means that the 128 bits following the current sample cycle can be written to). An [OutputCopyError](#) is triggered if an attempt is made to write output sample data to a location outside of this window.

In Automation Studio, with the setting "Output control mode = Single", this register is set to 128 bits and with the setting "Output control mode = Continuous" it is set to 255 bits.

| Data type | Value | Information |
|-----------|----------|---------------|
| USINT | 0 to 255 | Output window |

9.26.5.9.8.10 Configuration of the outputs of the oversampling channels

Name:

CfO_OversampleConfigOutput

"Oversample I/O 01 → Output" to "Oversample I/O 04 → Output" in the Automation Studio I/O configuration

"Oversample I/O 01 → Output control" to "Oversample I/O 04 → Output control" in the Automation Studio I/O configuration

"Oversample I/O 01 → Output default state" to "Oversample I/O 04 → Output default state" in the Automation Studio I/O configuration

This register helps configure the outputs of the individual oversample channels.

The "Output default state" bits determine which level the respective output assumes before oversampling is started. Furthermore, the output is set to the defined "Output default state" in the event of an error.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------------------------------|-------|--|
| 0 - 1 | Number of the physical output channel | 0 | Output channel 1 |
| | | 1 | Output channel 2 |
| | | 2 | Output channel 3 |
| | | 3 | Output channel 4 |
| 2 - 3 | Reserved | - | |
| 4 - 5 | Output operation | 1 | Output can be reset by the oversample channel. |
| | | 2 | Output can be set by the oversample channel. |
| | | 3 | Output can be set and cleared by the oversample channel. |
| 6 - 7 | Default value output | 0 | Last value |
| | | 1 | Output cleared by default |
| | | 2 | Output set by default |

9.26.5.9.8.11 Oversampling configuration

Name:

OversampleEnable

OversampleOutputValidate

The oversampling and copy process for the output buffer can be configured in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------|-------|--|
| 0 | OversampleEnable | 0 | Disables oversampling (with the next reference cycle) |
| | | 1 | Enables oversampling (with the next reference cycle) |
| 1 | OversampleOutputValidate | 0 | Disable the copy procedure to the output control buffer. |
| | | 1 | Enables the copy procedure to the output control buffer. <ul style="list-style-type: none"> Used to synchronize the oversampling procedure at startup. This makes it possible to prevent new data from being transferred to the "OversampleOutput0NSample" on page 3011 registers in each X2X cycle. |
| 2 - 7 | Reserved | - | |

9.26.5.9.8.12 Address of the new output sampling data in the output control buffer

Name:

OversampleOutputCycle

When absolute addressing of the output control buffer is being used, this register specifies the address from which the new output sample data should be copied to the output control buffer.

| Data type | Values | Information |
|-----------|----------|--------------------------------------|
| USINT | 0 to 255 | Address of the output control buffer |

9.26.5.9.8.13 Offset of new output sample data

Name:

OversampleSampleOffset

When relative addressing of the output control buffer is being used, this register serves as the offset for the new output sample data. Sample address at the time of the [reference cycle](#) + Offset = address to which the new output sample data is copied in the output control buffer).

| Data type | Value | Information |
|-----------|----------|------------------------------|
| USINT | 0 to 255 | Offset of output sample data |

9.26.5.9.8.14 Oversample output sample data

Name:

OversampleOutput01Sample1_8 to OversampleOutput04Sample1_8
 OversampleOutput01Sample9_16 to OversampleOutput04Sample9_16
 OversampleOutput01Sample17_24 to OversampleOutput04Sample17_24
 OversampleOutput01Sample25_32 to OversampleOutput04Sample25_32
 OversampleOutput01Sample33_40 to OversampleOutput04Sample33_40
 OversampleOutput01Sample41_48 to OversampleOutput04Sample41_48
 OversampleOutput01Sample49_56 to OversampleOutput04Sample49_56
 OversampleOutput01Sample57_64 to OversampleOutput04Sample57_64

Contains the oversample output sample data. Up to 64 samples (8 bytes) for each oversample I/O channel can be synchronously transferred with a X2X cycle. This data is copied to the specified address (absolute or relative) in the output control buffer at the set [output copy cycle](#). 1 bit of this data is then output during each "sample cycle" to the physical output that is assigned to the oversample I/O channel.

Bit 0 of "OversampleOutputSample8_1" is copied to the output control buffer first, meaning that it is the first bit that is output. "OversampleOutputSample64_57" bit 7 is the last bit to be output.

| Data type | Values | Information |
|-----------|----------|--------------------|
| USINT | 0 to 255 | Output sample data |

Example

Assignment of "OversampleOutputSample" register data to output signal

9.26.5.9.8.15 Input status buffer address of the input sample data

Name:

OversampleInputCycle

The value in this register can be used to reference absolute addressing of the output control buffer.

| Data type | Value | Information |
|-----------|----------|-----------------------------|
| USINT | 0 to 255 | Input status buffer address |

9.26.5.9.9 PWM

9.26.5.9.9.1 Period duration

Name:

CfO_PWM01_Periode to CfO_PWM04_Periode

This register can be used to set the period duration between 20 and 1000 μ s.

| Data type | Value | Information |
|-----------|------------|--|
| UINT | 20 to 1000 | The period duration is specified in μ s. |

9.26.5.9.9.2 Excitation current

Name:

CfO_PWM01_Duty1 to CfO_PWM04_Duty1

This value is enabled from the time the output is switched on until the configured excitation time expires.

| Data type | Value | Information |
|-----------|-------|-----------------------|
| UINT | 0 | Output statically off |
| | 1000 | Output statically on |

9.26.5.9.9.3 Holding current

Name:

CfO_PWM01_Duty2 to CfO_PWM04_Duty2

This value is enabled if the output is switched on and the configured excitation time is expired.

| Data type | Value | Information |
|-----------|-------|-----------------------|
| UINT | 0 | Output statically off |
| | 1000 | Output statically on |

9.26.5.9.9.4 Excitation time

Name:

CfO_PWM01_Duty1Time to CfO_PWM04_Duty1Time

The excitation time is configured in steps in this register according to the [Excitation time base](#). The excitation time starts running as soon as the output is switched on. When the output is switched off, the excitation time is reset and the physical output disabled.

| Data type | Value | Information |
|-----------|------------|---|
| UINT | 0 to 65000 | Definition of the excitation time in steps according to the time base |

9.26.5.9.9.5 Excitation time base

Name:

CfO_PWM01_Duty1TimeBase to CfO_PWM04_Duty1TimeBase

The time base for the [Excitation time](#) is set in this register.

| Data type | Value | Information |
|-----------|-----------|--|
| UINT | 0 to 1000 | The time base for the excitation time is specified in μ s. |

9.26.5.9.9.6 High-speed cutoff

Name:

CfO_PWM01_FastSwitchOff to CfO_PWM04_FastSwitchOff

Setting this register enables/disables the high-speed cutoff after switching off the output.

| Data type | Value | Information |
|-----------|-------|----------------------------|
| UINT | 0 | High-speed cutoff disabled |
| | 1 | High-speed cutoff enabled |

Difference between normal and high-speed cutoff

- ①, ③ PWM period duration
- ② PWM excitation current value
- ④ PWM holding current value

9.26.5.9.9.7 PWM update timestamp

Name:

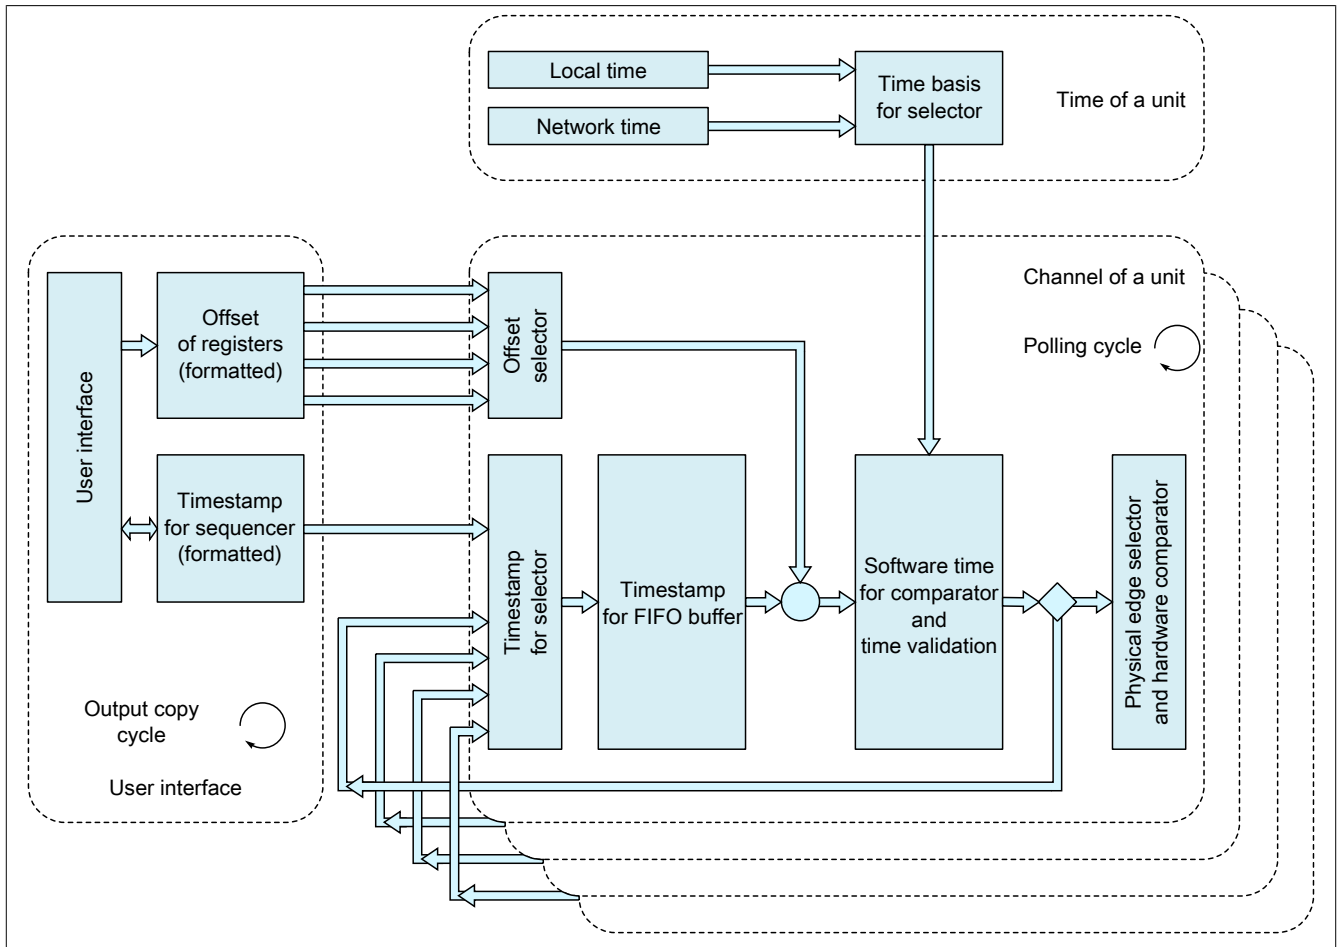

CfO_PWM_UpdateCycle

This register sets the time of data output.

| Data type | Value | Information |
|-----------|-------|---------------------------------|
| USINT | 10 | X2X cycle optimized (no jitter) |
| | 15 | Fast reaction (with jitter) |

9.26.5.9.10 Edge generator

The edge generator is based on 4 units. The units are able to generate edges independently of the X2X cycle. For each unit, up to 4 timestamps can be set per X2X cycle. The individual edges can then be referenced to this timestamp or to other edges using an offset.

9.26.5.9.10.1 Mode "DigitalCamSwitch"

"Unit 0x" in the Automation Studio I/O configuration.

Mode "DigitalCamSwitch" can additionally be selected for each unit when configuring the edge generator in Automation Studio.

In this mode, all configuration and operation takes place exclusively using the function blocks in motion library "ASMCDcs". For more information, see the corresponding ASMCDcs function block descriptions.

9.26.5.9.10.2 Preparing data for edge generation by hardware comparators

Name:

CfO_EdgeGenPollCycleEventID

"Generation cycle" in the Automation Studio I/O configuration.

To ensure edge output with μs precision, edge generation is based on internal hardware components. One such comparator is available for one rising and one falling edge respectively for each physical output channel. The data for the comparators is prepared in "EdgeGenPollCycle". Therefore, a maximum of one rising and one falling edge can be generated for each physical output channel per "EdgeGenPollCycle". If [timestamps](#) are set that cannot be processed in time due to this limitation, then an [EdgeGenWarning](#) is generated. Processing of such timestamps is made up for as quickly as possible, as long as they are within [EdgeGenUnitPickupDiff](#).

A shorter "Generation cycle" means that an enabled edge generator function has a less negative effect on the minimum X2X cycle time.

| Data type | Value | Information |
|-----------|-------|------------------------|
| USINT | 2 | System timer |
| | 3 | Prescaled system timer |

9.26.5.9.10.3 Moment when output data is applied for edge generation

Name:

CfO_EdgeGenConsumeCycleEventID

This register determines when the output data for edge generation is applied within the X2X cycle.

| Data type | Value | Information |
|-----------|-------|--|
| USINT | 10 | "X2X cycle optimized" The data is force-applied between the periods ASYNC IN (AI) and ASYNC OUT (AO). |
| | 15 | "Fast reaction (with jitter)" The data is applied immediately after SYNC OUT (SO) processing. |

Setting "Fast reaction" results in jitter because the copy cycle of the SYNC OUT data can take different amounts of time. However, this only affects the moment at which the internal copy cycle takes place and therefore possibly also the earliest possible timestamp. [Timestamps](#) that are set outside of this jitter range are not affected by this.

9.26.5.9.10.4 Configuration of units

Name:

CfO_EdgeGenUnit01Mode to CfO_EdgeGenUnit04Mode

"Time base" in the Automation Studio I/O configuration

"Timestamp format" in the Automation Studio I/O configuration.

"Offset format" in the Automation Studio I/O configuration.

"Unit 01" to "Unit 04" in the Automation Studio I/O configuration

These registers contain the configuration bits for the respective units.

If "timestamp resolution = 1/8 μ s" is used, be aware that the timestamp data must also have a resolution of 1/8 μ s. Because the CPU system time and the X2X NetTime only have μ s resolution, the system time or the NetTime must be offset by 3 bits to the left or multiplied by 8 in the application. This value can then be used as reference for timestamps with a resolution of 1/8 μ s. It is also possible to use 1/8 μ s timestamps from input edges as a reference.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

When using the NetTime with 1/8 μ s resolution, the synchronization jitter affects the output results (see ["Synchronization jitter" on page 2998](#)).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|-------------|
| 0 | Resolution of the timestamp | 0 | 1 μ s |
| | | 1 | 1/8 μ s |
| 1 | Number of bits in the timestamp register | 0 | 16-bit |
| | | 1 | 32-bit |
| 2 | Offset resolution | 0 | 1 μ s |
| | | 1 | 1/8 μ s |
| 3 | Number of bits in the offset register | 0 | 16-bit |
| | | 1 | 32-bit |
| 4 | Time base | 0 | NetTime |
| 5 - 6 | Reserved | - | |
| 7 | Enable/disable units | 0 | Disabled |
| | | 1 | Enabled |

9.26.5.9.10.5 Number of timestamps for FIFO

Name:

CfO_EdgeGenUnit01TimestampFifoLim to CfO_EdgeGenUnit04TimestampFifoLim

These registers define how many timestamps can be transferred to the FIFO buffer of a unit. The FIFO buffer serves as a memory buffer for timestamps in the future. Timestamps must be entered in the FIFO buffer in the same order in which they should be output. This means it is not possible to set a timestamp in the future followed by an earlier timestamp. The ["EdgeGenSequenceReadback" on page 3019](#) register can be used to indicate if the defined limit has been reached.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Value | Information |
|-----------|---------|-------------|
| USINT | 1 to 12 | FIFO limit |

9.26.5.9.10.6 Number of timestamps per X2X cycle

Name:

CfO_EdgeGenUnit01TimestampRegCount to CfO_EdgeGenUnit04TimestampRegCount

"Timestamp elements" in the Automation Studio I/O configuration.

This register determines how many timestamps can be transferred per X2X cycle.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Value | Information |
|-----------|--------|------------------------------------|
| USINT | 1 to 4 | Number of timestamps per X2X cycle |

9.26.5.9.10.7 Pickup difference to be regained for timestamps

Name:

CfO_EdgeGenUnit01PickupDiff to CfO_EdgeGenUnit04PickupDiff

These registers determine how far in the past timestamps can be so that they can still be picked up. Timestamps in the past are processed as quickly as possible as long as they fall within the pickup difference specified in this register. [EdgeGenWarning](#) is triggered if a timestamp was not able to be processed in time and its difference had to be regained. If a timestamp could not be picked up because it was outside the pickup difference window, then both "EdgeGenWarning" and "EdgeGenError" are reported.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

In Automation Studio, if "Timestamp format = 16-bit" this register is initialized with 65535 (0xFFFF), and if "Timestamp format = 32-bit" it is initialized with 134,217,728 (0x8000000).

| Data type | Value | Information |
|-----------|------------------|--|
| UDINT | 0 to 65535 | Difference to be regained in μ s when "Offset format = 16-bit" |
| | 0 to 134,217,728 | Difference to be regained in μ s when "Offset format = 32-bit" |

9.26.5.9.10.8 Configuration of edge properties for each unit

Name:

CfO_EdgeGenUnit01ConfigEdge0 to CfO_EdgeGenUnit04ConfigEdge0

CfO_EdgeGenUnit01ConfigEdge1 to CfO_EdgeGenUnit04ConfigEdge1

CfO_EdgeGenUnit01ConfigEdge2 to CfO_EdgeGenUnit04ConfigEdge2

CfO_EdgeGenUnit01ConfigEdge3 to CfO_EdgeGenUnit04ConfigEdge3

"Unit 01 → Edge" to "Unit 04 → Edge" in the Automation Studio I/O configuration.

"Unit 01 → Operating mode" to "Unit 04 → Operating mode" in the Automation Studio I/O configuration.

"Unit 01 → Offset" to "Unit 04 → Offset" in the Automation Studio I/O configuration.

"Unit 01 → Unit 01" to "Unit 04 → Unit 01" in the Automation Studio I/O configuration.

The property of each of the 4 edges of a unit can be configured in these registers.

Ring-shaped chain of edges

If the individual edges are chained together in a ring (e.g. edge 2 is relative to edge 1 and edge 1 is relative to edge 2), then a head must be defined for the ring using bit 11 "Ring-shaped chain" so that this type of cycle can start without a timestamp. In Automation Studio, bit 11 "Ring-shaped chain" is set for edge 1 for all units by default. If this type of ring is branched (e.g. a third edge is relative to an edge within the ring), then it is important to make sure that the internal FIFO buffer, which is available to every physical I/O edge, does not overflow. This happens if more than 12 edges are generated by the ring but should not be output until much later. If this situation occurs – a ring generates edges even though the FIFO buffer is full, then [EdgeGenError](#) is triggered.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--------------------------|--------|--|
| 0 - 4 | Physical edge | 0 | Rising edge on channel 1 |
| | | 1 | Rising edge on channel 2 |
| | | 2 | Rising edge on channel 3 |
| | | 3 | Rising edge on channel 4 |
| | | 16 | Falling edge on channel 1 |
| | | 17 | Falling edge on channel 2 |
| | | 18 | Falling edge on channel 3 |
| | | 19 | Falling edge on channel 4 |
| 5 - 7 | Reserved | - | |
| 8 - 10 | Timestamp of FIFO source | 0 | User interface, absolute |
| | | 1 to 3 | Reserved |
| | | 4 | Edge 1, relative |
| | | 5 | Edge 2, relative |
| | | 6 | Edge 3, relative |
| | | 7 | Edge 4, relative |
| | | 11 | Ring-shaped chain Default in Automation Studio for "Edge 01 = 1", "Edge 02 = 0", "Edge 03 = 0", "Edge 04 = 0" |
| | | 1 | Enabled |
| 12 - 13 | Offset register numbers | 0 | Offset register 0 |
| | | 1 | Offset register 1 |
| | | 2 | Offset register 2 |
| | | 3 | Offset register 3 |
| 14 | Reserved | - | |
| 15 | Switching edge on/off | 0 | Disabled |
| | | 1 | Enabled |

9.26.5.9.10.9 Enabling units

Name:

EdgeGen01Enable to EdgeGen04Enable

EdgeGen01EnableReadback to EdgeGen04EnableReadback

"Unit 01" to "Unit 04" in the Automation Studio I/O configuration

The different units of the edge generator can be enabled/disabled using this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------------------|-------|-------------|
| 0 | EdgeGen01Enable | 0 | Disabled |
| | EdgeGen01EnableReadback | 1 | Enabled |
| 1 - 7 | Reserved | - | |

9.26.5.9.10.10 Sequence number for generating switching edges

Name:

EdgeGen01Sequence to EdgeGen04Sequence

If new timestamp data is to be applied to the module, then the sequence number must be increased by the number of timestamp elements that must be applied. If multiple elements are transferred within one X2X cycle, then you must make sure that the individual **timestamps** are placed in the FIFO buffer in the same order in which they occur chronologically. Data from **EdgeGenTimestamp** arrives in the FIFO buffer first; data from "EdgeGenTimestamp1" arrives last.

| Data type | Value | Information |
|-----------|-------------|--|
| SINT | -128 to 127 | Sequence number for generating switching edges |

9.26.5.9.10.11 Last sequence number applied by the module for edge generation.

Name:

EdgeGen01SequenceReadback to EdgeGen04SequenceReadback

The sequence number is read back in this register. Like register "**EdgeGenSequence**" on page 3019, this register is incremented if the specified **timestamps** can also be recorded by the module. If the module is not able to record any new timestamps (e.g. because **EdgeGenUnitTimestampFifoLim** has been reached), then this register indicates the number of the last sequence recorded by the module.

| Data type | Value | Information |
|-----------|-------------|--|
| SINT | -128 to 127 | Last sequence number accepted by the module for edge generation. |

9.26.5.9.10.12 Offset formats

Automation Studio provides 3 different parameters for setting offsets.

- **Offset format:** This parameter allows you to select the file type (16- or 32-bit) for cyclic transfer and only affects "**EdgeGenOffset**" on page 3019 registers.
Acyclic transfer of offset values with register "**CfO_EdgeGenOffset_32bit**" on page 3020 is not affected by this parameter and always remains 32 bits wide.
- **Offset 01 to Offset 04:** This parameter has 2 possible settings:
 - Initial configuration: The offset value is only written once during configuration.
 - Cyclic data: A data point is created in the Automation Studio I/O mapping and the offset value is written cyclically.
- **Offset 01 value to Offset 04 value:** The actual offset value.

Offset per unit - Transferred once during configuration

Name:

EdgeGen01Offset1 to EdgeGen04Offset1

...

EdgeGen01Offset4 to EdgeGen04Offset4

"Offset 01 value" to "Offset 04 value" in the Automation Studio I/O configuration

The 4 offsets of an edge generator unit are written in this register. Depending on the configuration in register "**Edge generator unit mode**" on page 3016, the offset values are handled in μs or $1/8 \mu\text{s}$ steps.

For information regarding how to use the register and set the offset formats in Automation Studio, see "**Offset formats**" on page 3019.

| Data type | Value | Information |
|-----------|--------------------|--|
| UINT | 0 to 65,535 | 16-bit offset |
| UDINT | 0 to 134,217,728 | Offset when "Offset format = 32-bit" and "Time base" = 1 μs |
| | 0 to 1,073,741,824 | Offset when "Offset format = 32-bit" and "Time base" = 1/8 μs |

Offset per unit - Acyclic transfer

Name:

CfO_EdgeGen01Offset_32bit1 to CfO_EdgeGen04Offset_32bit1

...

CfO_EdgeGen01Offset_32bit4 to CfO_EdgeGen04Offset_32bit4

The 4 offsets of an edge generator unit can be written acyclically using these registers. Depending on the configuration in register "Edge generator unit mode" on page 3016, the offset values are handled in μs or $1/8 \mu\text{s}$ steps.

For information regarding how to use the register and set the offset formats in Automation Studio, see "Offset formats" on page 3019.

| Data type | Value | Information |
|-----------|--------------------|--|
| UDINT | 0 to 134,217,728 | Offset when "Offset format = 32-bit" and "Time base" = $1 \mu\text{s}$ |
| | 0 to 1,073,741,824 | Offset when "Offset format = 32-bit" and "Time base" = $1/8 \mu\text{s}$ |

9.26.5.9.10.13 Timestamp registers

Name:

EdgeGen01Timestamp1 to EdgeGen04Timestamp1

...

EdgeGen01Timestamp4 to EdgeGen04Timestamp4

Registers for the timestamps to which edges pending generation are referenced. Up to 4 timestamp elements can be transferred per X2X cycle. Between 1 and 4 of these timestamp elements are placed in the FIFO, depending on how much the sequence number is increased by. If an attempt is made to set timestamps to a time that has already passed, then [EdgeGenWarning](#) is generated (see register "CfO_EdgeGenUnitPickupDiff" on page 3017).

For more information about NetTime and timestamps, see "NetTime Technology" on page 3035.

| Data type | Value |
|-----------|---------------------------------|
| INT | -32768 to 32767 |
| DINT | -2,147,483,648 to 2,147,483,647 |

9.26.5.9.11 NetTime Technology

For a description of NetTime Technology, see "NetTime Technology" on page 3035.

9.26.5.9.12 Minimum X2X cycle time

The minimum X2X cycle time is strongly dependent on the configured functions and the resulting load on the module. Setting "Fast reaction" and a very short system cycle ($<50 \mu\text{s}$) generally have a negative effect on the minimum X2X cycle time. This can result in error behavior with short X2X cycle times.

9.26.6 X20CM4800X

Data sheet version: 1.02

9.26.6.1 Order data

| Model number | Short description | Figure |

Table 539: X20CM4800X - Order data

9.26.6.2 Module description

The module is intended for vibration measurement on machines and systems as well as for further evaluation of the data on the controller. The module has 4 input channels, whereby the selected sampling rate per input can be set between 200 Hz and 50 kHz.

Functions:

- [Configuration of inputs](#)
- [Vibration measurement](#)
- [NetTime timestamp](#)

If a measurement is started, the vibrations are measured with the set sampling and transferred with a configurable data resolution of 16, 24 or 32 bits.

A NetTime timestamp is generated when the measurement is started. This allows each recorded measured value to be assigned to a unique time. If the measurement is stopped, an additional NetTime timestamp is generated.

9.26.6.3 Technical data

| | |
|---|---|
| Model number | X20CM4800X |
| Short description | |
| I/O module | X20 4-channel analog input module for vibration measurement of condition monitoring tasks |
| General information | |
| Isolation voltage between channel and bus | 500 V _{eff} |
| Nominal voltage | 24 VDC ±20% |
| B&R ID code | 0xF1C5 |
| Status indicators | Run, error, vibration inputs 1 to 4 |
| Diagnostics | |
| Module run/error | Yes, using LED status indicator and software |
| Power consumption | |
| Bus | 0.01 W |
| Internal I/O | 1.5 W |
| Certifications | |

9.26.6.10 Function description

9.26.6.10.1 Configuration of inputs

There is only a limited number of bytes available for transferring raw data to the X2X Link network that are distributed among all active channels. In order to make more bytes available on the channels used, unused channels can be switched off.

In addition, the IEPE sensor power supply can be enabled separately for each channel. If a sensor is connected to multiple channels, the power supply must be enabled for one channel only.

Information:

Registers are described in section "[Channel configuration](#)" on page 3032.

9.26.6.10.1.1 Data resolution

The data is scaled by the module according to the set data resolution:

| Mode | Data format | Maximum value +10 V | Minimum value -10 V | Scaling |
|--------|-------------|---------------------------|---------------------------|---|
| 16-bit | INT | 32767 (0x7FFF) | -32767 (0x8000) | Shifted 8 bits to the right |
| 24-bit | DINT | 8388607 (0x7FFFFFF) | -8388608 (0x8000000) | Internal converter resolution of the module ¹⁾ |
| 32-bit | DINT | 2147483392 (0x7FFFFFFF00) | -2147483648 (0x800000000) | Shifted 8 bits to the left. Bits 0 to 7 are always 0. |

1) The 3 bytes must be transferred from the application in a DINT. For negative values, bits 25 to 31 must be set to 1.

9.26.6.10.2 Vibration measurement

Up to 4 vibration sensors can be connected to the module. The raw data of the sensors is recorded with the set sampling rate and resolution.

However, processing and evaluation of the transferred data must be carried out in the application. For a description of how to convert raw data into a vibration value, see "[Converting raw data to \[mg\]](#)" on page 3029.

Information:

There is no preprocessing of the data within the module.

9.26.6.10.2.1 Converting raw data to [mg]

The following formulas can be used to convert the raw value into a vibration value [mg]:

$$\text{Sensor resolution} = 0.0001 \cdot \frac{\text{V}}{\text{mg}}$$

$$\text{Vibration value [mg]} = \text{Raw value} \cdot \left(\frac{\text{MaximumResolution}_{10\text{V_AnalogIn}}}{\text{MaximumValue}_{10\text{V_DigitalIn}}} \right) \cdot \frac{1}{\text{Sensor resolution}}$$

Information:

The maximum resolution always depends on the sensor used. The module operates in the range of ± 10 V. For a 100 mV/g sensor, this corresponds to a maximum value of ± 100 g. With a 50 mV/g sensor, the maximum value is ± 200 g.

Example

A 100 mV/g sensor is used; the module provides the value 4608 as a raw value and the data resolution is configured to 24 bits. This results in the following values for the calculation:

- Raw value = 4608
- MaximumValue_10V_AnalogIn = 10 V (module value, cannot be changed)
- MaximumValue_10V_DigitalIn with 24 bits = 8388607 (see "Data resolution" on page 3028)
- Sensor resolution = 100 mV/g = 0.1 V/g = 0.0001 V/mg

$$\text{Vibration value [mg]} = 4608 \cdot \left(\frac{10 \text{ V}}{8388607} \right) \cdot \frac{1}{0.0001 \text{ V/mg}} = 54.93 \text{ mg}$$

9.26.6.10.2.2 Flatstream

The data interface for the raw data is based on Flatstream communication. Operation takes place using library "AsFitGen".

Information:

Each channel has its own Flatstream.

For information about library "AsFitGen", see Automation Help.

The required bytes for transmitting the raw data at the Flatstream depend on the set sampling rate, the set data resolution and the bus cycle time used.

Information:

If the raw data is not transferred to the controller fast enough, it is buffered in the module per channel. As soon as the buffer is full, error message **BufferOverflow** occurs.

Calculation example for required number of bytes

The following settings are made for a measurement evaluation:

- Bus cycle time: 2 ms
- Sampling rate: 2 kHz (one value every 500 μ s)
- Data resolution: 16 bits (2 bytes)

In the bus cycle time of 2 ms, this results in 4 values of 2 bytes each – a total of 8 bytes. The Flatstream data interface must be configured in accordance with this calculation.

If the bus cycle time is reduced from 2 ms to 1 ms, the number of bytes required for the raw data is reduced by half, i.e. 4 bytes. This means that other channels have more bytes available.

Setting the MTU size

The MTU size to be set for the Flatstream is equal to the calculated data bytes + 1 control byte. Therefore, the input MTU size must be configured to at least $8 + 1 = 9$ bytes, or in the second case, to $4 + 1 = 5$ bytes.

Since this is only the ideal value, reserve bytes must still be planned to compensate for any timing tolerances or communication errors. Otherwise, it could happen that not all data can be transferred in time, causing a buffer overflow at some point.

9.26.6.10.3 NetTime

If a measurement is started for a channel, a timestamp is automatically determined for the first raw value. The configured sampling rate can then be used to establish a unique time reference for each raw value.

In addition, a timestamp is automatically determined again even after the measurement has been completed.

Information:

The timestamps for the other raw values must be determined by the application. The module only provides the start or end timestamp.

Information:

Registers are described in section ["NetTime" on page 3034](#).

9.26.6.11.2 Configuration

9.26.6.11.2.1 Channel configuration

Name:

CfO_ChannelConfig01 to CfO_ChannelConfig04

CfO_ChannelConfig01_rb CfO_ChannelConfig04_rb

These registers can be used to configure the respective channels.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|-------------------------------|-------|------------------------------|
| 0 | Enables/Disables channel | 0 | Channel disabled |
| | | 1 | Channel enabled |
| 1 | Sensor power supply | 0 | Sensor power supply disabled |
| | | 1 | Sensor power supply enabled |
| 2 - 3 | Data resolution ¹⁾ | 0 | 32-bit |
| | | 1 | 24-bit |
| | | 2 | 16-bit |
| 4 - 7 | Sampling rate ²⁾ | 0 | 50000 Hz |
| | | 1 | 25000 Hz |
| | | 2 | 10000 Hz |
| | | 3 | 5000 Hz |
| | | 4 | 2500 Hz |
| | | 5 | 2000 Hz |
| | | 6 | 1000 Hz |
| | | 7 | 500 Hz |
| 8 - 15 | Reserved | 8 | 200 Hz |
| | | 0 | |

1) The maximum or minimum value of the respective resolution corresponds to ± 10 VAC.

2) The sampling rate of an analog signal with respect to 1 second. Specified in [Hz].

Examples:

- Sampling an analog signal once per second corresponds to a sampling rate of 1 Hz.
- Sampling an analog signal once per millisecond corresponds to a sampling rate of 1 kHz.

9.26.6.11.3 Communication

9.26.6.11.3.1 Starting/stopping measurements and buffer overflow

Name:

Measurement01 to Measurement04

BufferOverflowAck01 to BufferOverflowAck04

In this register, the measurements can be started or stopped. In addition, a potential buffer overflow can be acknowledged.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|---------------------|-------|--|
| 0 | Measurement01 | 0 | Stop measurement of channel 1 |
| | | 1 | Start measurement of channel 1 |
| ... | | ... | |
| 3 | Measurement04 | 0 | Stop measurement of channel 4 |
| | | 1 | Start measurement of channel 4 |
| 4 | BufferOverflowAck01 | 0 | Do not acknowledge channel 1 buffer overflow |
| | | 1 | Acknowledge channel 1 buffer overflow |
| ... | | ... | |
| 7 | BufferOverflowAck04 | 0 | Do not acknowledge channel 4 buffer overflow |
| | | 1 | Acknowledge channel 4 buffer overflow |

9.26.6.11.3.2 Status of the module

Name:

MeasurementState01 to MeasurementState04

BufferOverflow01 to BufferOverflow04

BrokenWire01 to BrokenWire04

This register specifies the module status.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--------------------|-------|----------------------------------|
| 0 | MeasurementState01 | 0 | Measurement of channel 1 stopped |
| | | 1 | Measurement of channel 1 running |
| ... | | ... | |
| 3 | MeasurementState04 | 0 | Measurement of channel 4 stopped |
| | | 1 | Measurement of channel 4 running |
| 4 | BufferOverflow01 | 0 | No buffer overflow on channel 1 |
| | | 1 | Buffer overflow on channel 1 |
| ... | | ... | |
| 7 | BufferOverflow04 | 0 | No buffer overflow on channel 4 |
| | | 1 | Buffer overflow on channel 4 |
| 8 | BrokenWire01 | 0 | No error on channel 1 |
| | | 1 | Open circuit - Channel 1 |
| ... | | ... | |
| 11 | BrokenWire04 | 0 | No error on channel 4 |
| | | 1 | Open circuit - Channel 4 |
| 12 - 15 | Reserved | - | |

BufferOverflow

Each channel is equipped with an internal buffer of 50 kB. Depending on the set sampling rate, data resolution and MTU size, a buffer overflow occurs at the earliest after approx. 250 ms if the data is not transferred via Flatstream. The overflow must be acknowledged by the application using register [BufferOverflowAck0x](#).

9.26.6.11.4 NetTime**9.26.6.11.4.1 Time of first valid scan**

Name:

Nettime_StartMeasCh01 to Nettime_StartMeasCh04

The register writes the timestamp of the first valid sample after the measurements are started.

| Data type | Values | Information |
|-----------|------------------------------------|----------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Timestamp in μ s |

9.26.6.11.4.2 Time of last valid scan

Name:

Nettime_StopMeasCh01 to Nettime_StopMeasCh04

The register writes the timestamp of the last valid sample. The timestamp of the last valid sample of a measurement is available after measurement has ended.

| Data type | Values | Information |
|-----------|------------------------------------|----------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Timestamp in μ s |

9.26.6.11.4.3 NetTime Technology

NetTime refers to the ability to precisely synchronize and transfer system times between individual components of the controller or network (CPU, I/O modules, X2X Link, POWERLINK, etc.).

This allows the moment that events occur to be determined system-wide with microsecond precision. Upcoming events can also be executed precisely at a specified moment.

Time information

Various time information is available in the controller or on the network:

- System time (on the PLC, Automation PC, etc.)
- X2X Link time (for each X2X Link network)
- POWERLINK time (for each POWERLINK network)
- Time data points of I/O modules

The NetTime is based on 32-bit counters, which are increased with microsecond resolution. The sign of the time information changes after 35 min, 47 s, 483 ms and 648 μ s; an overflow occurs after 71 min, 34 s, 967 ms and 296 μ s.

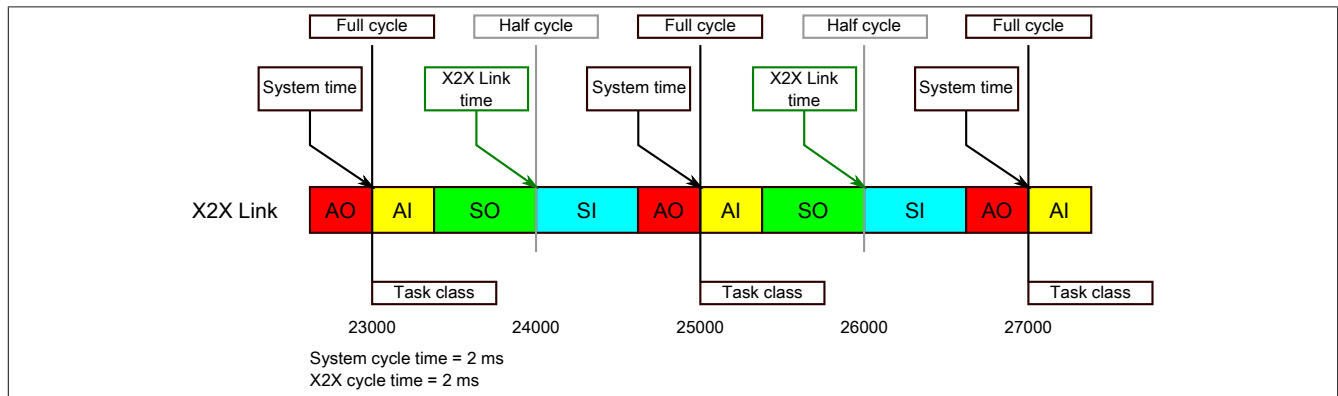

The initialization of the times is based on the system time during the startup of the X2X Link, the I/O modules or the POWERLINK interface.

Current time information in the application can also be determined via library AsIOTime.

PLC/Controller data points

The NetTime I/O data points of the PLC or the controller are latched to each system clock and made available.

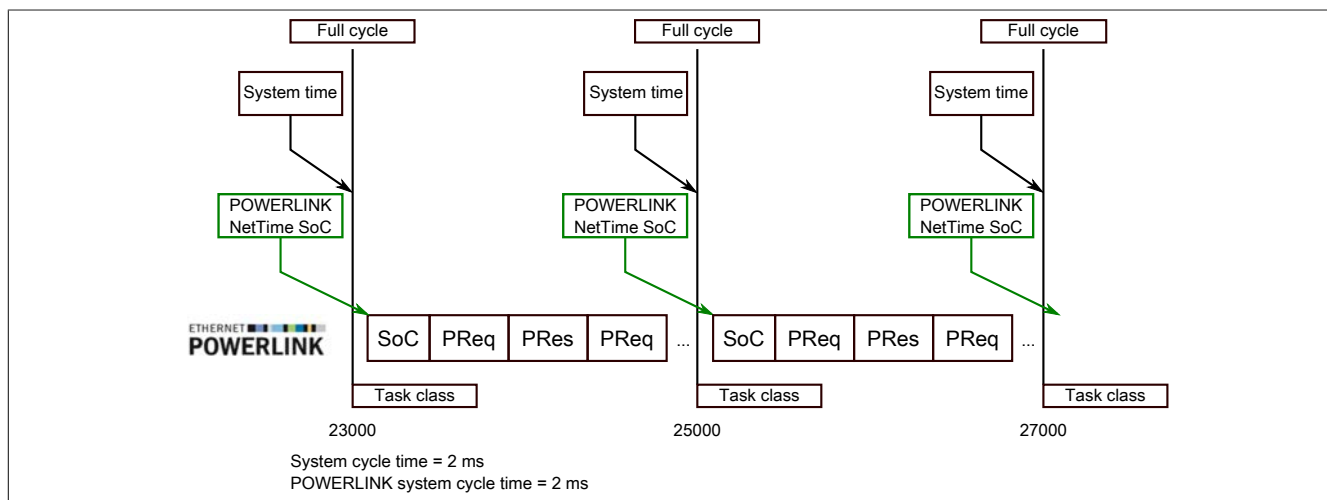

X2X Link reference moment

The reference moment on the X2X Link network is always calculated at the half cycle of the X2X Link cycle. This results in a difference between the system time and the X2X Link reference moment when the reference time is read out.

In the example above, this results in a difference of 1 ms, i.e. if the system time and X2X Link reference moment are compared at time 25000 in the task, then the system time returns the value 25000 and the X2X Link reference moment returns the value 24000.

POWERLINK reference moment

The reference moment on the POWERLINK network is always calculated at the start of cycle (SoC) of the POWERLINK network. The SoC starts 20 μ s after the system tick. This results in the following difference between the system time and the POWERLINK reference time:

POWERLINK reference time = System time - POWERLINK cycle time + 20 μ s.

In the example above, this means a difference of 1980 μ s, i.e. if the system time and POWERLINK reference moment are compared at time 25000 in the task, then the system time returns the value 25000 and the POWERLINK reference moment returns the value 23020.

Synchronization of system time/POWERLINK time and I/O module

At startup, the internal counters for the PLC/POWERLINK (1) and the I/O module (2) start at different times and increase the values with microsecond resolution.

At the beginning of each X2X Link cycle, the PLC or the POWERLINK network sends time information to the I/O module. The I/O module compares this time information with the module's internal time and forms a difference (green line) between the two times and stores it.

When a NetTime event (E) occurs, the internal module time is read out and corrected with the stored difference value (brown line). This means that the exact system moment (S) of an event can always be determined, even if the counters are not absolutely synchronous.

Note

The deviation from the clock signal is strongly exaggerated in the picture as a red line.

Timestamp functions

NetTime-capable modules provide various timestamp functions depending on the scope of functions. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

For details, see the respective module documentation.

Time-based inputs

NetTime Technology can be used to determine the exact moment of a rising edge at an input. The rising and falling edges can also be detected and the duration between 2 events can be determined.

Information:

The determined moment always lies in the past.

Time-based outputs

NetTime Technology can be used to specify the exact moment of a rising edge on an output. The rising and falling edges can also be specified and a pulse pattern generated from them.

Information:

The specified time must always be in the future, and the set X2X Link cycle time must be taken into account for the definition of the moment.

Time-based measurements

NetTime Technology can be used to determine the exact moment of a measurement that has taken place. Both the starting and end moment of the measurement can be transmitted.

9.26.6.11.5 Flatstream communication

For a description of Flatstream communication, see ["Flatstream communication" on page 3802](#)

9.26.6.11.6 Required cycle time

The cycle time depends on the sampling rate, data resolution and MTU size. It must be selected such that no buffer overflow occurs when the measured values are transmitted via the Flatstream.

9.26.7 X20(c)CM4810

Data sheet version: 2.20

9.26.7.1 General information

This compact module provides a system for measuring and analyzing vibrations for use in applications such as condition monitoring for machinery and equipment.

The measurement unit consists of 4 vibration inputs with 24-bit converter resolution and a sampling frequency of 51.562 kHz. Each of the inputs has a separately activated constant current source to supply IEPE sensors.

Signal conditioning algorithms integrated in the module include configurable high and low-pass filters, an envelope curve generator and a Fourier transform, among many others.

Various parameters and configurable frequency bands are available to ensure seamless signal evaluation. The module performs calculations internally to minimize the load on the bus and CPU.

Whether used for traditional condition monitoring or as a means of process optimization, the maximum evaluable frequency of 10 kHz and maximum frequency resolution of under 63 mHz make it suitable for almost any application. If desired, it can also be used as a standard input module.

The ability to upload all values in the time and frequency domain also allow measurements to be evaluated externally or archived.

Information:

The X20CM4810 module is supported starting with Automation Studio 3.0.90.x and Automation Runtime versions ≥ J3.09, J4.01 and O4.02.

- 4-channel vibration measurement and analysis module
- 24-bit resolution at 51.562 kHz
- IEPE supply
- Internal calculation of an extensive range of condition parameters
- Data buffer upload

9.26.7.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.26.7.5 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-------|-------------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Warning, error or reset status |
| | e + r | | Red on and green single flash | Invalid firmware |
| | 1 - 4 | Green | On | Status of the respective acceleration sensor (no open circuit) |

- 1) Depending on the configuration, a [firmware update](#) can take up to several minutes.

9.26.7.6 Firmware update time

Due to the large size of the firmware, the firmware update takes some time.

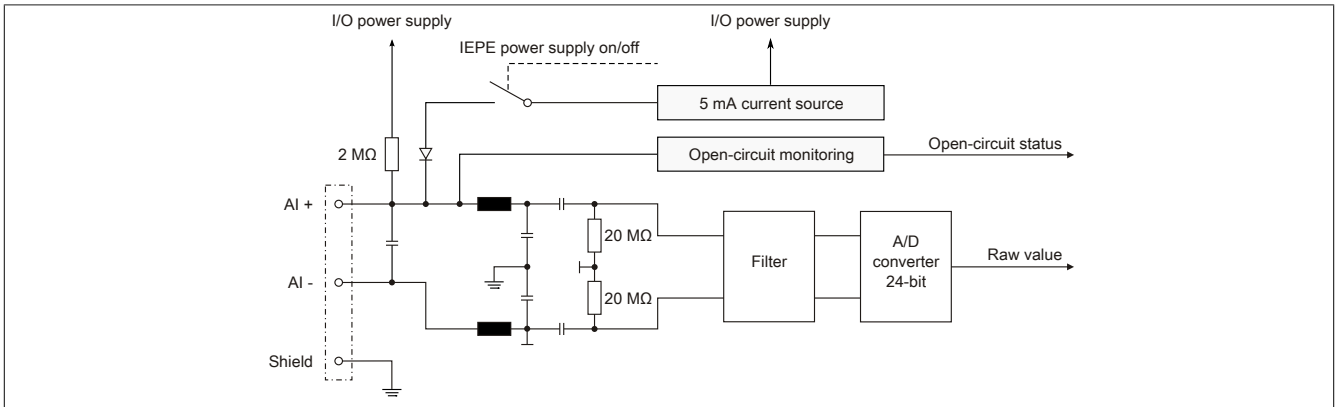

The following firmware update times can be expected depending on the configured bus cycle time:

| Bus cycle time | Update time |
|----------------|----------------|
| 400 µs | Approx. 3 min |
| 2 ms | Approx. 15 min |

9.26.7.7 Pinout

9.26.7.8 Input circuit diagram

9.26.7.9 Shielding

There are 2 ways to shield the cable for the acceleration sensors:

- Shielding possibilities on the terminal block. (Contact "Acc. sensor 1 - 4 shield")
- X20 shielding on the bus module. (See the "Shielding" section in the X20 system user's manual)

Shielding via the terminal block is perfectly sufficient for environments with no special EMC requirements.

However, if the module is used in an environment with special EMC requirements and high frequency disturbances, both options should be used together.

9.26.7.10 Derating

Horizontal installation

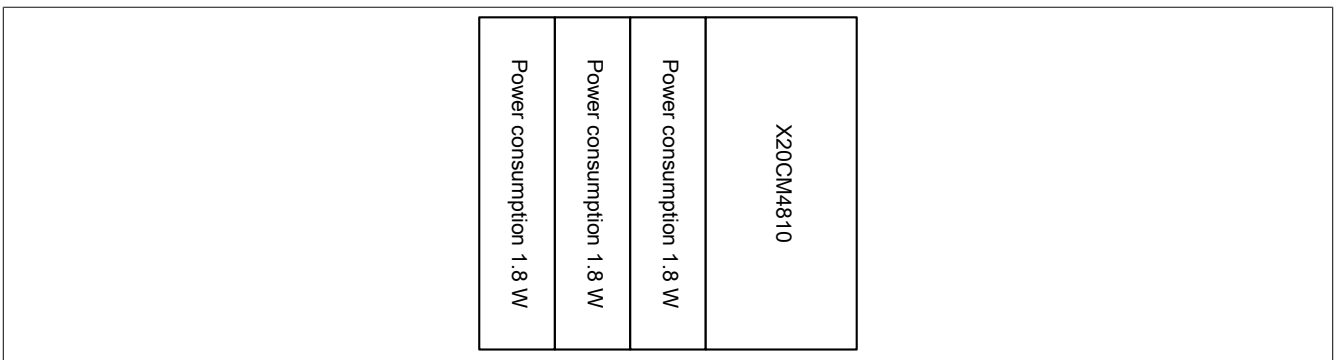

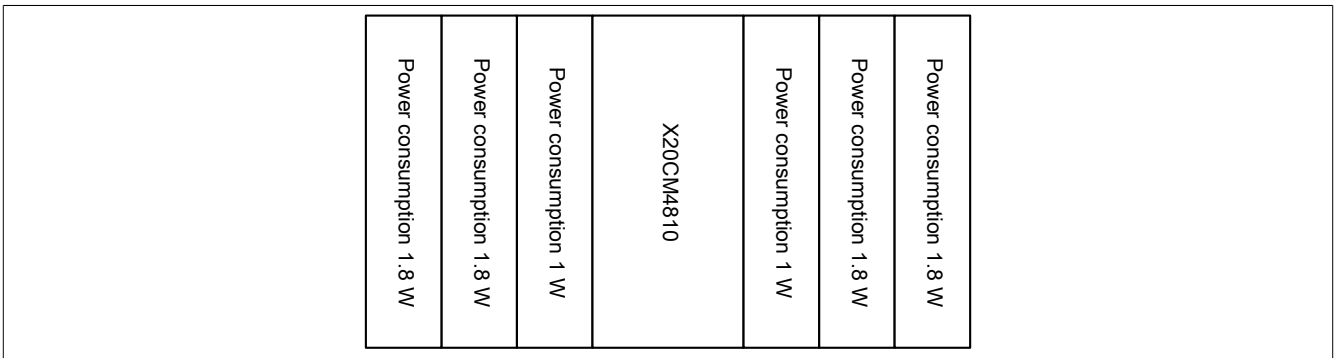

At ambient temperatures higher than 45°C, the X20CM4810 requires power derating:

If the X20CM4810 is to be operated with ambient temperatures up to 50°C, then the neighboring modules must not consume more than 1 W.

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

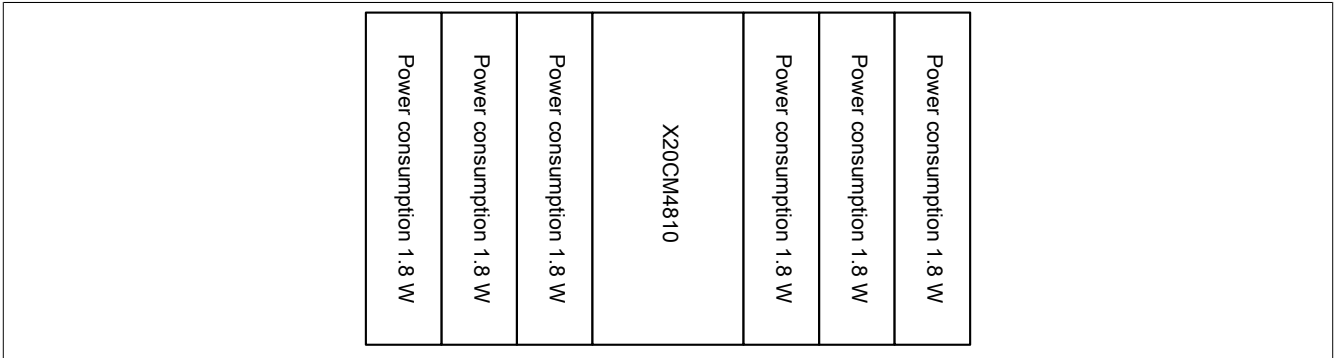

Example: ambient temperature up to 50°C

X20 double-width modules are an exception. It is also possible, for example, to place multiple X20CM4810 modules next to one another.

Example: ambient temperature up to 45°C

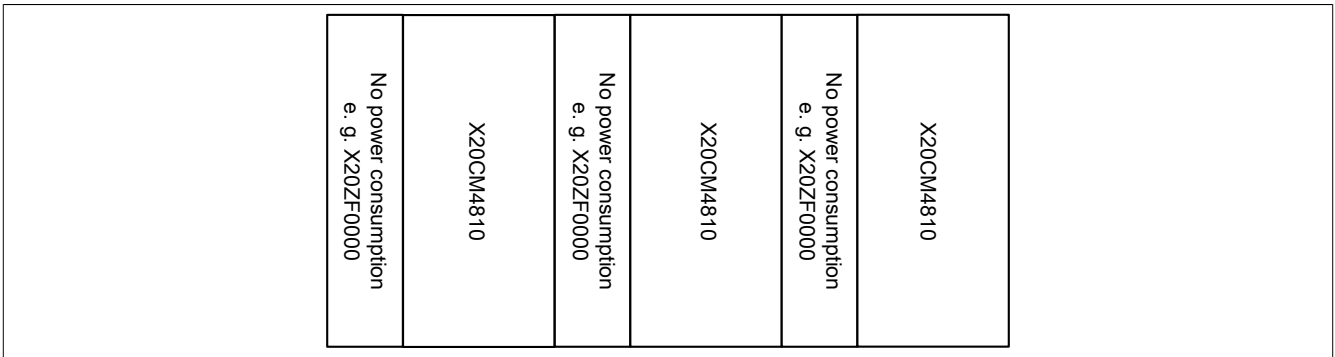

Vertical installation

At ambient temperatures higher than 35 °C, the X20CM4810 requires power derating:

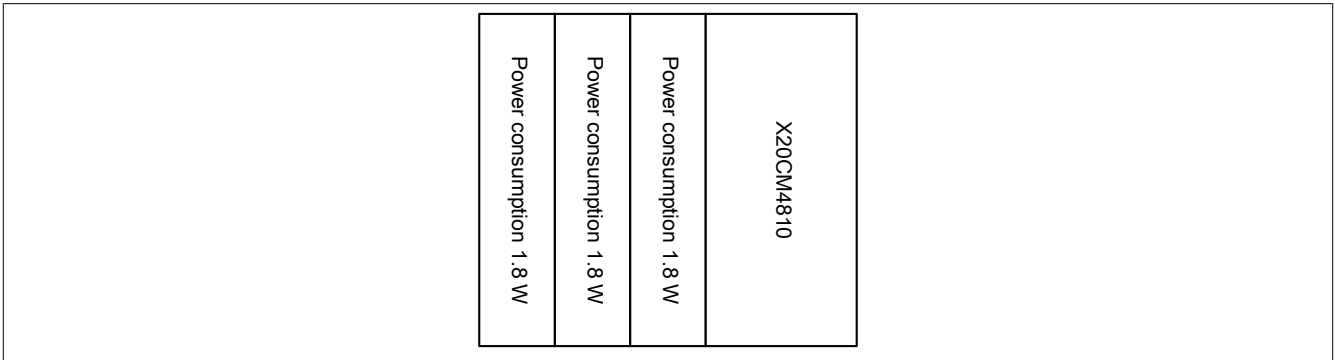

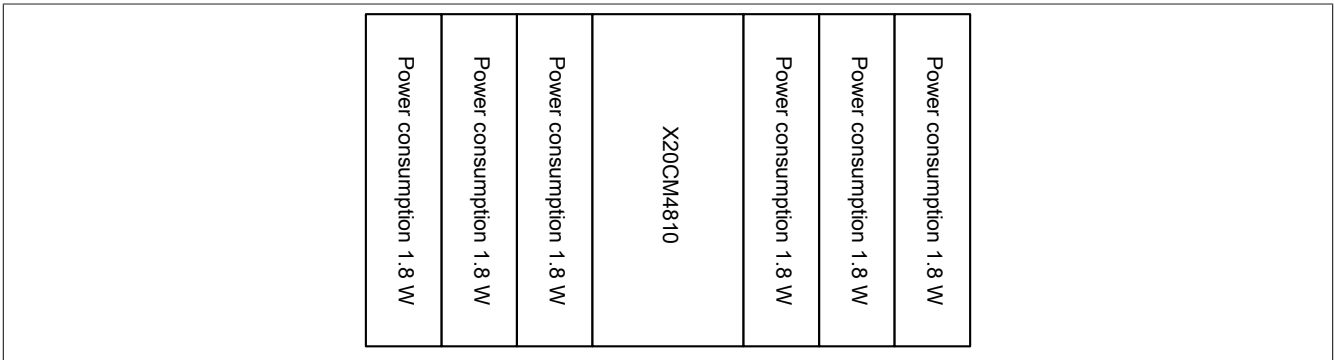

If the X20CM4810 is to be operated with ambient temperatures up to 45°C, then the neighboring modules must not consume power.

Example: ambient temperature up to 45°C

Example: ambient temperature up to 35°C

X20 double-width modules are an exception. For example, multiple neighboring X20CM4810 modules can be operated up to an ambient temperature of 30°C.

9.26.7.11 Gain curve

The following diagram shows a typical gain curve for the module.

9.26.7.12 Settling time

The input high-pass cutoff frequency of the AC voltage input (limit frequency of 34 MHz) means that a certain amount of settling time is required after changing the DC offset of the pending signal.

- Settling time of approximately 30 seconds at 100 mV/g sensor sensitivity and a 24 V supply voltage with an accuracy of 0.4 g
- Settling time of approximately 60 seconds at 100 mV/g sensor sensitivity and a 24 V supply voltage with an accuracy of 0.001 g
- The respective settling time must be allowed to pass in order to achieve accurate measurement results when an open line occurs. Because of this, all characteristic values and analog input values are set to 0 by the module during the first 30 seconds after a restart or wire breakage.

9.26.7.13 Sensor sensitivity

The module always assumes a 100 mV/g acceleration sensor on the input. When using [Function model 0 - Standard](#), it is possible to configure a different sensor sensitivity using the "[SensitivitySensor](#)" on [page 3069](#) register.

If a different function model is used, for example an SGC controller or bus controller, any conversion to a different sensitivity must be performed manually.

Example

Factor = 100 / (sensor sensitivity in mV/g)

All values must be multiplied by the calculated factor. This also applies to the analog characteristic values if the characteristic value calculation is enabled as well as for uploaded time signals and amplitude spectra. Exempt from this are all characteristic values without any units, such as "[KurtosisRaw](#)" on [page 3077](#), "[CrestFactorRaw](#)" on [page 3075](#) and "[SkewnessRaw](#)" on [page 3078](#).

9.26.7.14 Using a B&R Compact CPU or fieldbus CPU

Due to the size of the firmware for the module, only CPUs with sufficient ROM (> 1MB) are supported. (X20CP0292 or X20XC0292)

9.26.7.15 Register description

9.26.7.15.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.26.7.15.2 Function model 0 - Standard

This is the default function model for the module. The calculated module characteristic values are streamed from the module via Flatstream every 300 ms and prepared for the user by Automation Runtime. If the streamed data is not collected by the next transfer, the characteristic values of the next measurement are lost. For this reason, the maximum cycle time must be observed for an error-free evaluation.

Analog inputs are provided as cyclic data points.

To help the user, all of the module's characteristic values – such as Flatstream handling for characteristic values, unit scaling and so on – are prepared in this function model using Automation Runtime and then made available to the user. See ["Automation Runtime support" on page 3066](#).

With this function model, it is also possible to upload data from the module via another Flatstream data buffer. Library **AsIOVib** is available for uploading the buffers from the module. For a description of the library, see ["Automation Help - Programming - Libraries - Direct I/O access - AsIOVib"](#).

In this function model, the module can only be configured using the I/O configuration. No registers are permitted to be reconfigured acyclically.

| Register | Name | Data type | Read | | Write | |

9.26.7.15.3 Function model 1 - Fast master

The characteristic values calculated by the module are streamed to the master every 300 ms via Flatstream. If the streamed data is not collected by the next transfer, the characteristic values of the next measurement are lost. For this reason, the maximum cycle time must be observed for an error-free evaluation.

With this function model, it is also possible to use an additional Flatstream to read data buffers from the module.

Analog inputs are provided as cyclic data points.

This function model can only be used on Ethernet-based masters and SGC or fieldbus CPUs. However, it must be ensured that Flatstream handling is implemented on the master and that the module changes the data in the Flatstream in every X2X cycle.

| Register | Name | Data type | Read | | Write | |

9.26.7.15.4 Function model 2 - Slow master

This function model was developed specifically for operating the module with "slow masters" and for conserving resources on the PLC.

With this function model, it is not possible to upload data buffers from the module.

Analog inputs are provided as cyclic data points. Scaling of the characteristic values must be performed manually.

Characteristic values are calculated by the module every 300 ms and can only be read via acyclic access. In order to keep all characteristic values consistent with one another, they can be locked as they are read. This function model does not allow for seamless measurements. The Min/Max functionality can be used for seamless measurements, however. See ["Characteristic values \(minimum and maximum\)" on page 3079](#)

This function model is recommended for all slow buses and masters. It is important to note that acyclic register access must be implemented on the master if a B&R master is not being used.

| Register | Name | Data type | Read | | Write | |
|--|---|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |

9.26.7.15.5 Function model 254 - Bus controller

This function model can only be used with a CANIO bus controller. It includes the same functionality as [Function model 2 - Slow master](#).

Differences:

- The order of cyclic registers is somewhat different on the bus.
- Since the AnalogInputToggleBit01-04 data points cannot be consistently transferred to the "AnalogInput" on page 3061 data points, they are not available in this function model. The user must watch for changes in the value of the data points "AnalogInput" in order to determine whether a new value is available.

1) The offset specifies the position of the register within the CAN object.

9.26.7.15.5.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.7.15.5.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.26.7.15.6 General information

9.26.7.15.6.1 Signal generation

The following signals and characteristic values are calculated from the acceleration sensor's input signal:

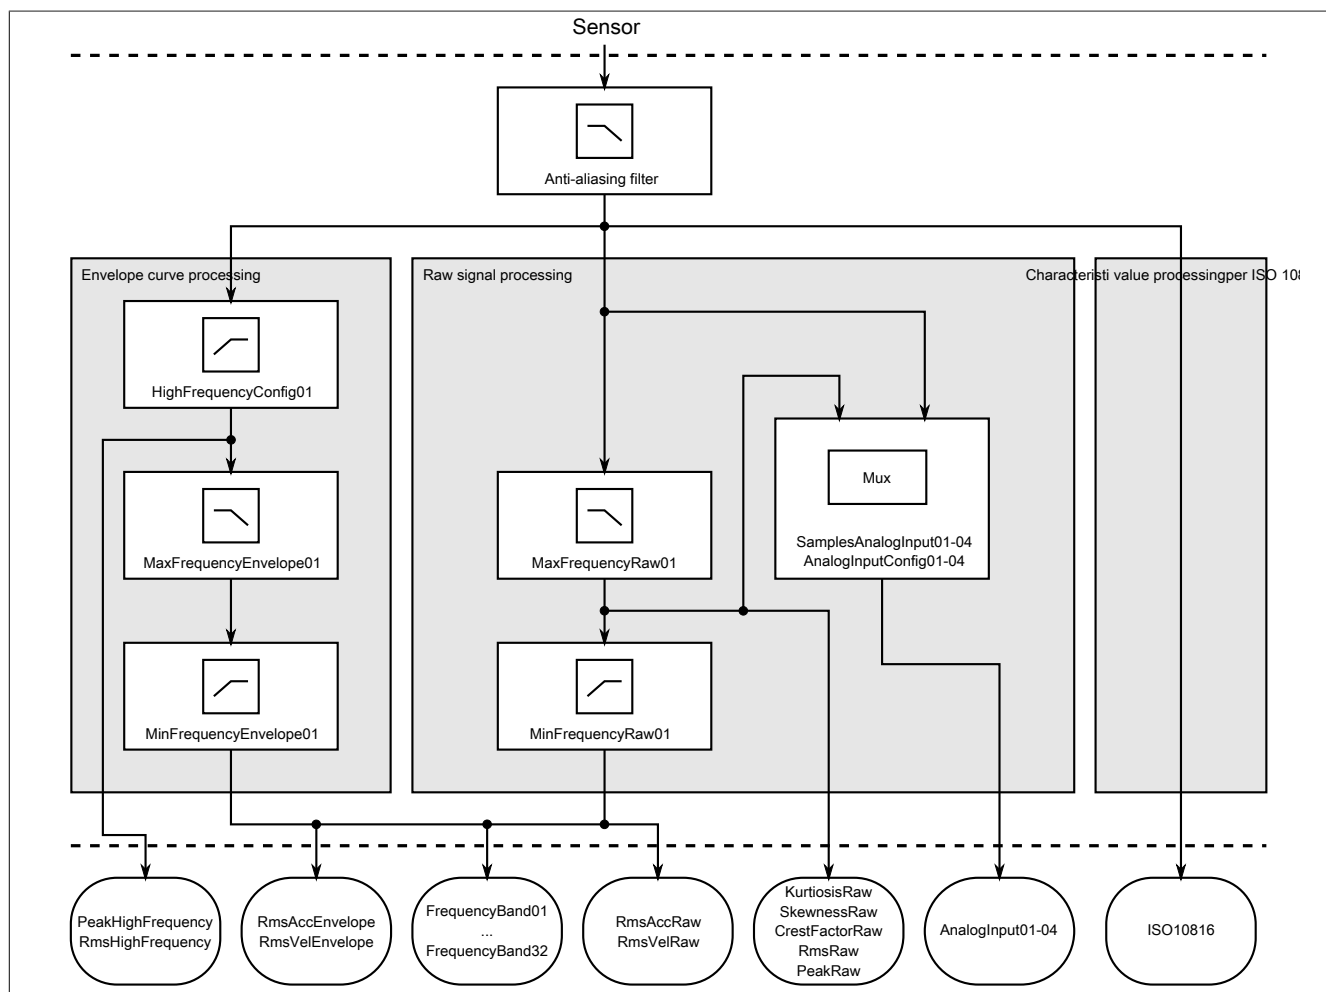

Figure 198: Signal generation in the module

9.26.7.15.6.2 Filter configuration

The module has a number of configurable filters.

There is a configurable high-pass filter for the whole module that can be configured using register "[HighFrequencyConfig](#)" on page 3085. Possible settings are 500 Hz, 1 kHz and 2 kHz. This high-pass affects all high-frequency and envelope characteristic values of all module channels.

In addition, there are 2 adjustable low pass filters per channel.

- Filtering of the raw signal. This filter is configured using register "[MaxFrequencyRaw](#)" on page 3086. Possible settings are 200 Hz, 500 Hz, 1 kHz, 2 kHz, 5 kHz and 10 kHz.
- Filtering of the envelope signal. This filter is configured using register "[MaxFrequencyEnvelope](#)" on page 3085. Possible settings are 200 Hz, 500 Hz, 1 kHz and 2 kHz.

These low-pass filters affect all calculated characteristic values of the respective signal, i.e. the raw or envelope signal. They can be used to increase the frequency resolution of the FFT. For the characteristic value calculation in the analog input, however, it can be selected whether the characteristic values are to be calculated from the direct input signal or the low-pass filtered raw signal.

9.26.7.15.6.3 Frequency bands

It is possible to individually configure up to 32 frequency bands where the RMS value (RMS) or the noise of a quadrant is calculated.

| Parameter | Settings | | |
|-------------------------------------|---|---|------------|
| Enable | Off RMS Noise | | |
| Channel | 1 2 3 4 | | |
| Source | Raw acceleration signal Raw velocity signal Enveloped acceleration signal Enveloped velocity signal | | |
| Calculation of harmonics (RMS only) | Yes No | | |
| Rotation-dependent (RMS only) | On | Selects the data point for velocity (" ActSpeed " on page 3056) | [1/100 Hz] |
| | | Standardized damage frequency at 60 rpm | [1/100] |
| | Off | ± Width of the frequency band (tolerance band) | [1/100 Hz] |
| | | Lower frequency | [1/4 Hz] |
| | Upper frequency | [1/4 Hz] | |
| Quadrant (noise only) | 1st quadrant 2nd quadrant 3rd quadrant 4th quadrant | | |

9.26.7.15.6.4 Calculating the velocity signal automatically

The module can calculate the velocity signal from the signal provided by the acceleration sensor. This calculation is disabled by default since it can reduce the accuracy of the acceleration signal.

Reason

When converting from acceleration to velocity, low frequency portions become very large. As a result, the [autogain](#) is decreased by a few levels, which then further degrades accuracy.

If this calculation is not enabled, 0 is output for all characteristic values calculated from the velocity spectrum. Characteristic value "[Iso10816](#)" on page 3072 is not affected by this.

9.26.7.15.6.5 Autogain, AutogainDelay and overflow

The module automatically adjusts the measurement signal dynamically (autogain) to ensure that it is measured with the highest possible accuracy. This adjustment is made in multiple steps. Each step amplifies the input signal more than the last. If the signal was very small for a long time and an impact suddenly occurs, an overflow may occur with some calculated characteristic values. This is indicated by the overflow bit for the respective channel (Overflow01-04 in the "[Status](#)" on page 3059 register) being set and the affected module characteristic values being set to their maximum.

With [Function model 0 - Standard](#), there are also the "[OverflowCharacteristicValues](#)" on page 3067 and "[OverflowFrequencyBands](#)" on page 3068 registers. These are automatically generated by Automation Runtime and directly indicate the overflow status of the individual characteristic values and frequency bands.

If an overflow occurs or if an internal threshold is exceeded, the autogain for the next measurement is reduced by one level. If no overflow occurs for a certain number of measurements (adjustable using the "[AutogainDelay](#)" on page 3056 register), or the signal stays below the internal threshold, the autogain is increased by one level again.

If overflows are occurring frequently, increasing AutogainDelay may help.

9.26.7.15.6.6 Term definition: Sampling rate and sampling frequency

The terms sampling rate and sampling frequency are used in this document. The following is a definition of these terms:

| Term | Definition |
|--------------------|---|
| Sampling rate | Number of times an analog signal is sampled per unit of time. The unit of time is generally 1 second. Example: 100 samples per second |
| Sampling frequency | Sampling of an analog signal with respect to 1 second. Specified in Hertz [Hz]. Examples: <ul style="list-style-type: none"> • Sampling an analog signal once per second corresponds to a sampling frequency of 1 Hz. • Sampling an analog signal once per millisecond corresponds to a sampling frequency of 1 kHz. |

9.26.7.15.7 General registers

9.26.7.15.7.1 ActSpeed

Name:

ActSpeed01 to ActSpeed04

Registers for the current speed for calculating frequency bands 01 to 32 if they have been configured as speed-dependent.

The current speed must be specified in 1/100 Hz. In [Function model 0 - Standard](#), Automation Runtime handles this.

If the 4 different speed data points are not sufficient, e.g. for several different gear ratios, the speed ratio can also be included when calculating the standardized damage frequency for the frequency band ("[FrequencyBandDmgFreq60rpm](#)" on page 3095 register).

Characteristic value in [Function model 0 - Standard](#)

| Format | Values | Unit |
|--------|---------------------------|---------|
| REAL | 0 to 655.35 ¹⁾ | in 1 Hz |

1) The driver reduces larger values to 655.35.

Characteristic value in all other function models

| Format | Values | Unit |
|--------|-------------|-------------|
| UINT | 0 to 65,535 | in 1/100 Hz |

9.26.7.15.7.2 AutogainDelay

Name:

AutogainDelay01

This register can be used to configure the autogain delay for all 4 channels.

To ensure that even smaller signals can be calculated precisely, the autogain can be increased in steps. This happens if there has been no overflow in the number of measurement cycles configured in this register and all conditions for the next step were always met. If an overflow does occur, then autogain is reduced immediately by one step.

The unit for delaying autogain is specified in measurement cycles (300 ms).

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 1 to 65,535 | Number of measurement cycles. Bus controller default setting: 50 |

9.26.7.15.7.3 AutogainDelayRead

Name:

AutogainDelay01Read

Register for reading the current "[AutogainDelay](#)" on page 3056 configuration.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.7.4 Control

Name:

Control01

General control register for the module.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 | RequestBufferLock01 or RequestDataLock01 | 0 | Data should not be locked. |
| | | 1 | Data should be locked. |
| 1 | MinMaxUpdate01 | x | The acyclic minimum and maximum values are refreshed at each edge |
| 2 - 15 | Reserved | 0 | |

RequestBufferLock01 or RequestDataLock01

"Function model 0 - Standard" and "1 - Fast master"

RequestBufferLock01 can be used to lock all buffers and parameters on the module. When the bit is set to 1, all buffers (raw data and FFT) are locked starting at the beginning of the next measurement. Before a buffer can be uploaded, all the data it contains must be locked.

The characteristic values associated with the locked buffers are transferred in the Flatstream characteristic values as soon as BufferLockValid01 = 1.

Information:

Since the measurement is universal, the parameters associated with the buffers are only transferred once.

"Function model 2 - Slow master" and "254 - Bus controller"

RequestDataLock01 can be used to lock all parameters on the module. When the bit is set to 1, then a consistent version of all measured values is retained until the next measurement. Once all data on the module has been locked, all the calculated characteristic values can be read acyclically from the module.

Data on the module is only locked once bit BufferLockValid01 or DataLockValid01 in register "Status01" on page 3059 is set.

Once the data has been uploaded, the RequestBufferLock01 or RequestDataLock01 bit can be reset to 0. Once BufferLockValid01 or DataLockValid01 in register "Status01" on page 3059 are back to 0, the data on the module is no longer locked.

A new freezing is only permitted by the module if the buffers of the channel with the largest buffer length are filled again. The buffer length depends on the settings of registers "MaxFrequencyRaw" on page 3086 and "MaxFrequencyEnvelope" on page 3085.

MinMaxUpdate01

An edge on MinMaxUpdate01 updates all acyclic minimum and maximum values. A new cycle then starts internally to generate the minimum and maximum values that are again copied to the acyclic registers on the next edge. Once an edge has been reached, the current minimum and maximum values can be read acyclically in the next X2X cycle. Register "MinMaxCounter" on page 3081 specifies how many measurement cycles were analyzed with minimum and maximum mapping. The minimum/maximum values themselves are only valid if the counter has a value other than 0.

9.26.7.15.7.5 SensorConfig

Name:

SensorConfig01

This register can be used to enable or disable the IEPE sensor supply for individual channels.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|--------------------------------------|-------|---|
| 0 | Channel 1: IEPE supply | 0 | Off (bus controller default setting) |
| | | 1 | On |
| ... | | ... | |
| 3 | Channel 4: IEPE supply | 0 | Off (bus controller default setting) |
| | | 1 | On |
| 4 - 7 | Reserved | 0 | |
| 8 | Channel 1: EnableVelocityCalculation | 0 | No calculation (bus controller default setting) |
| | | 1 | Calculation enabled |
| ... | | ... | |
| 11 | Channel 4: EnableVelocityCalculation | 0 | No calculation (bus controller default setting) |
| | | 1 | Calculation enabled |
| 12 - 13 | Reserved | 0 | |
| 14 | Buffer length | 0 | 8192 measured values (bus controller default setting) |
| | | 1 | 65535 measured values |
| 15 | Selects the function model | 0 | Function model 2 - Slow master and Function model 254 - Bus controller (bus controller default setting) |
| | | 1 | Function model 1 - Fast master |

EnableVelocityCalculation

This bit can be used to enable the calculation of all characteristic values calculated on the velocity spectrum.

If this calculation is not enabled, 0 is output for all characteristic values calculated on the velocity spectrum.

To maximize the precision of the characteristic values based on the acceleration spectrum, it is recommended to only enable this bit if the velocity signals are absolutely required.

9.26.7.15.7.6 SensorConfigRead

Name:

SensorConfig01Read

Register for reading the current "[SensorConfig](#)" on [page 3058](#) configuration.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.7.7 Status

Name:

Status01

General status register for the module.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|-------|---|
| 0 | Channel 1: BrokenWire01 | 0 | No error |
| | | 1 | Open circuit |
| ... | | ... | |
| 3 | Channel 4: BrokenWire04 | 0 | No error |
| | | 1 | Open circuit |
| 4 | BufferLockValid01 or DataLockValid01 ¹⁾ | 0 | Data not locked |
| | | 1 | Data locked, consistent and valid |
| 5 | Channel 1: Overflow01 | 0 | No error |
| | | 1 | Overflow of one or more characteristic values |
| ... | | ... | |
| 8 | Channel 4: Overflow04 | 0 | No error |
| | | 1 | Overflow of one or more characteristic values |
| 9 | Channel 1: AnalogInputToggleBit01 ²⁾ | 0 | Does not toggle |
| | | 1 | Toggles |
| ... | | ... | |
| 12 | Channel 4: AnalogInputToggleBit04 ²⁾ | 0 | Does not toggle |
| | | 1 | Toggles |
| 13 - 15 | Reserved | - | |

1) Confirmation of RequestBufferLock01 or RequestDataLock01 in register "Control" on page 3057

2) Toggles with each new calculation and each new input value in register "AnalogInput0x" on page 3061

9.26.7.15.8 Analog input functions

Each of the module's 4 accelerometer inputs can also be used directly as an analog input with various special functions (see register ["AnalogInput" on page 3061](#)).

The resolution of the analog inputs can be set using the configuration (["AnalogInputScale" on page 3064](#)). The lower the maximum value, the higher the resolution of the register and vice versa. When the maximum value is exceeded, the register is limited to the respective maximum (positive or negative).

A toggle bit ([AnalogInputToggleBit01-04](#)) signals when a new value has been transferred.

The following functions are available:

- Normal analog input function
- Characteristic value calculation in continuous mode with enable (continuous mode)
- Characteristic value calculation in trigger mode (single shot)

9.26.7.15.8.1 Measured values

The last 8 measured values before the X2X cycle are always averaged and transferred on the bus. Here, the direct input signal (raw signal max. 10 kHz) with a sampling frequency of 25.781 kHz is always used and is not mean-adjusted. The value is scaled according to the configuration. (see ["AnalogInputScale" on page 3064](#) register)

9.26.7.15.8.2 Characteristic value calculation in AnalogInput

The following characteristic values can be indicated directly in register ["AnalogInput" on page 3061](#). In this case, it is necessary to check the configured scale.

- Mean
- Peak value (absolute)
- RMS value
- Crest factor

There are 2 signals available to calculate the configured characteristic values:

- Input signal filtered to 10 kHz with a sampling frequency of 25.781 kHz and not mean-adjusted.
- Raw signal filtered to the maximum frequency with a sampling frequency that is dependent on the ["MaxFrequencyRaw" on page 3086](#) configuration and with mean adjustment using the last 8192 samples.

Register ["SamplesAnalogInput" on page 3065](#) can be used to set how many sampled values should be used to calculate the respective parameter. The time between 2 samples depends on the maximum frequency.

2 modes are available:

- ["Continuous mode with enable \(continuous mode\)" on page 3060](#)
- ["Trigger mode \(single shot\)" on page 3061](#)

Continuous mode with enable (continuous mode)

This mode offers the following advantages:

- When the parameters are configured correctly, nothing can be overlooked.
- Using "enable", measurement in the module can be started after an event or events can be hidden.
- The toggle bit toggles with every new value.

The following must be taken into consideration for the configuration:

- In order to guarantee seamless measurement, the sample time (number of samples * sample rate) must be longer than the X2X Link cycle (see register ["SamplesAnalogInput" on page 3065](#)).
- If a shorter sample time than the X2X Link cycle is configured, the last complete measurement is always transferred.

Information:

Values are lost in this mode. The measured values cannot be transferred to the bus because multiple values are calculated in each X2X Link cycle.

Trigger mode (single shot)

This mode offers the following advantages:

- Only one measurement is taken at a time.
- The trigger is edge-sensitive, so it can be retriggered in each X2X Link cycle.
- The toggle bit toggles with every new value.

The following must be taken into consideration for the configuration:

- A new trigger will be ignored during an ongoing measurement. The runtime on the bus can cause retriggering before the toggle bit has changed.
- If a shorter sample time than the X2X Link cycle time is configured, the last complete measurement is always transferred.
- In trigger mode, values are lost because the measured values are recorded acyclically to the X2X Link and cannot be synchronized continually.
- The trigger results in temporary synchronization with X2X Link.

9.26.7.15.8.3 AnalogInput

Name:

AnalogInput01 to AnalogInput04

Depending on the configuration, these registers contain

- The actual input value of the associated input averaged over the last 8 samples
- Or the characteristic value to be calculated using the configured number of samples

The value in the register is scaled according to the configuration of register "[AnalogInputScale](#)" on page 3064.

If scaling the value takes it outside of the permissible range of values for INT, then it will be limited to the minimum or maximum INT value. The overflow bit for the corresponding channel is not set in this case.

Information:

In Function model 0 - Standard, Automation Runtime automatically scales the analog input to mg or non-dimensional values (crest factor) while taking SensitivitySensor and AnalogInputScale into account. If the value of AnalogInput without sensor scaling exceeds the value range of AnalogInputScale related to 100 mV/g, the corresponding AnalogInputOverflow bit is set.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.26.7.15.8.4 AnalogInputConfig

Name:

AnalogInputConfig01

Register for configuring the characteristic value calculation in "AnalogInput" on page 3061. This is only needed if "SamplesAnalogInput" on page 3065 of the respective channel is greater than 0.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Description |
|-------|---|-------|---|
| 0 - 1 | Value to be calculated in AnalogInput01 | 0 | Mean value (bus controller default setting) |
| | | 1 | Peak value |
| | | 2 | RMS value |
| | | 3 | Crest factor |
| 2 - 3 | Value to be calculated in AnalogInput02 | x | For possible values, see bits 0-1. |
| 4 - 5 | Value to be calculated in AnalogInput03 | x | For possible values, see bits 0-1. |
| 6 - 7 | Value to be calculated in AnalogInput04 | x | For possible values, see bits 0-1. |
| 8 | Trigger mode of AnalogInput01 | 0 | Continuous with enable (bus controller default setting) |
| | | 1 | Once with trigger |
| ... | | ... | |
| 11 | Trigger mode of AnalogInput04 | 0 | Continuous with enable (bus controller default setting) |
| | | 1 | Once with trigger |
| 12 | Signal source for characteristic value calculation AnalogInput01 | 0 | Raw signal filtered to the configured maximum frequency (see "MaxFrequencyRaw" on page 3086) with mean value adjustment. ¹⁾ (Bus controller default setting) |
| | | 1 | Raw signal filtered to 10 kHz without mean adjustment |
| ... | | ... | |
| 15 | Signal source for characteristic value calculation of AnalogInput04 | 0 | Raw signal filtered to the configured maximum frequency (see "MaxFrequencyRaw" on page 3086) with mean value adjustment. ¹⁾ (Bus controller default setting) |
| | | 1 | Raw signal filtered to 10 kHz without mean adjustment |

1) The average of the last 8192 samples is used for mean adjustment.

9.26.7.15.8.5 AnalogInputConfigRead

Name:

AnalogInputConfig01Read

Register for reading the current AnalogInput01 configuration.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.8.6 AnalogInputControlByte

Name:

AnalogInputControlByte01

The control register for "AnalogInput" on page 3061 is only functional if the respective "SamplesAnalogInput" on page 3065 configuration register is greater than 0.

The configuration in "AnalogInputConfig" on page 3062 for the respective channel determines whether the respective bit is an enable or trigger bit.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|----------------------|-------|---|
| 0 | AnalogInputControl01 | x | See Function of the bit |
| ... | | ... | |
| 3 | AnalogInputControl04 | x | See Function of the bit |
| 4 - 15 | Reserved | 0 | |

Function of the bit

Function in continuous mode:

Bit to start the continuous characteristic value calculation of "AnalogInput".

0 = Calculation disabled

1 = Continuous calculation of characteristic values

Function in single-shot mode:

Bit to start a new characteristic value calculation of "AnalogInput".

0, 1 Every edge starts a new characteristic value calculation provided the previous one is already completed.

Characteristic value calculation

The characteristic value configured in "AnalogInputConfig" on page 3062 for the respective channel is calculated. The number of samples configured in "SamplesAnalogInput" on page 3065 is used. The calculated value is displayed in "AnalogInput" on page 3061 with the scaling of the respective channel configured in "AnalogInputScale" on page 3064. The value of AnalogInputToggleBit01-04 changes each time a new calculation takes place.

9.26.7.15.8.7 AnalogInputSamples

Name:

AnalogInputSamples01 to AnalogInputSamples04

If bit 15 of the respective "SamplesAnalogInput" on page 3065 register is 1, then this register cyclically defines the number of samples used to calculate characteristic values.

Information:

If the register is changed while a measurement is running, then the current measurement is discarded (AnalogInputToggleBit0X does not change). This is especially important to remember when using continuous mode with enable.

| Data type | Values | Information |
|-----------|-----------|--|
| UINT | 0 | Invalid |
| | 1 to 8191 | Characteristic value calculation active for the respective channel in the corresponding analog input |
| | >8191 | Invalid |

The time between 2 samples depends on register "MaxFrequencyRaw" on page 3086:

| Maximum frequency | Sampling time (time between 2 samples) |
|-------------------|--|
| 10000 Hz | 38.79 μ s |
| 5000 Hz | 77.58 μ s |
| 2000 Hz | 193.94 μ s |
| 1000 Hz | 387.88 μ s |
| 500 Hz | 775.76 μ s |
| 200 Hz | 1939.39 μ s |

9.26.7.15.8.8 AnalogInputScale

Name:

AnalogInputScale01

This register can be used to specify the scale of the 4 analog inputs ("[AnalogInput](#)" on page 3061). If the actual value is greater than the value configured in this register, the respective register for the analog input ("[AnalogInput](#)" on page 3061) is limited to the positive maximum (32767).

For example, if ± 128 is configured for AnalogInput04, then the 16 bits represent a value range of ± 128 g or without units if the crest factor has been calculated.

Information:

The configured scaling value is always based on a 100 mV/g sensor. Any sensor that has a different sensor sensitivity must be reflected in the configuration.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| UINT | See bit structure. | 0x8888 |

Bit structure:

| Bit | Description | Value | Information |
|---------|---------------------------|-------|--|
| 0 - 3 | Scaling for AnalogInput01 | 0 | Invalid |
| | | 1 | ± 1 |
| | | 2 | ± 2 |
| | | 3 | ± 4 |
| | | 4 | ± 8 |
| | | 5 | ± 16 |
| | | 6 | ± 32 |
| | | 7 | ± 64 |
| | | 8 | ± 128 (bus controller default setting) |
| 9 to 15 | Invalid | | |
| 4 - 7 | Scaling for AnalogInput02 | x | For possible values, see AnalogInput01. |
| 8 - 11 | Scaling for AnalogInput03 | x | For possible values, see AnalogInput01. |
| 12 - 15 | Scaling for AnalogInput04 | x | For possible values, see AnalogInput01. |

9.26.7.15.8.9 AnalogInputScaleRead

Name:

AnalogInputScale01Read

This register can be used to read the scale of the analog inputs ("[AnalogInput](#)" on page 3061).

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.8.10 SamplesAnalogInput

Name:

SamplesAnalogInput01 to SamplesAnalogInput04

If the corresponding SamplesAnalogInput register is equal to 0, then the "AnalogInput" on page 3061 registers will provide the current input value for the analog input.

If the SamplesAnalogInput register is greater than 0, the characteristic value configured in register "AnalogInput-Config" on page 3062 for the respective channel is calculated. For this, the number of samples configured in this register will be used and displayed in the corresponding AnalogInput with the configured scaling.

If bit 15 of this register equals 1, then the characteristic value configured in "AnalogInputConfig01" for the respective channel is calculated. However, the number of samples specified cyclically in register "AnalogInputSamples" on page 3063 is used and displayed in the associated analog input with the configured scaling.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure

| Bit | Explanation | Values | Information |
|--------|-------------|-----------|---|
| 0 - 14 | | 0 | No characteristic value calculation of the respective channel in the associated analog input (bus controller default setting) |
| | | 1 to 8191 | Characteristic value calculation active for the respective channel in the corresponding analog input |
| | | >8191 | Invalid |
| 15 | | 0 | Cyclic specification of samplings via register "AnalogInputSamples" on page 3063 (bus controller default setting) |
| | | 1 | Sampling defined cyclically according to configuration of this register |

The time between 2 samples depends on register "MaxFrequencyRaw" on page 3086:

| Maximum frequency | Sampling time (time between 2 samples) |
|-------------------|--|
| 10000 Hz | 38.79 μ s |
| 5000 Hz | 77.58 μ s |
| 2000 Hz | 193.94 μ s |
| 1000 Hz | 387.88 μ s |
| 500 Hz | 775.76 μ s |
| 200 Hz | 1939.39 μ s |

9.26.7.15.8.11 SamplesAnalogInputRead

Name:

SamplesAnalogInput01Read to SamplesAnalogInput04Read

Register for reading the current "SamplesAnalogInput" on page 3065 configuration.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.9 Automation Runtime support

In [Function model 0 - Standard](#), Automation Runtime also prepares some of the characteristic values calculated by the module for the user.

Information:

To ensure error-free evaluation, it is important to observe the maximum cycle time. The module streams the characteristic values it calculates every 300 ms via Flatstream. If the streamed data is not collected by the next transfer, the measured characteristic values are lost.

Other features provided by Automation Runtime support:

- **"ActSpeed"**: The module always expects a value in 0.01 Hz resolution on these data points. Automation Runtime support allows the user to specify can state the current speed directly in Hz in the "standard" function model.
- **"AnalogInput"**: The analog input is automatically scaled to the sensor resolution and with the defined AnalogInputScale. It is then made available to the user in mg. This scaling does not apply to the **"Crest factor"** on page 3075 since it is a non-dimensional value.
- **Characteristic values and frequency bands**: All characteristic values and frequency bands calculated by the module are flat and can be connected directly in the I/O mapping. They are already scaled to the correct sensor resolution and will be displayed in mg or mm/s or as non-dimensional values (kurtosis, crest factor, skewness and Vdi3832) depending on the characteristic value.
- **Additional characteristic values**: In addition to the characteristic values calculated by the module, the following characteristic values are also provided automatically via Automation Runtime:
 - **Vdi3832KtRaw01-04** Requires PeakRawRef and RmsRawRef as reference values and outputs the reference values used in the calculation to PeakRawRefCalculated and RmsRawRefCalculated.
 - **CrestFactorHighFrequency01-04** Ratio of the absolute maximum to the RMS value (**"Crest factor"** on page 3075) of the high-pass filtered input signal. (**"PeakHighFrequency"** on page 3071 and **"RmsHighFrequency"** on page 3073)
 - **Vdi3832KtHighFrequency01-04** Requires PeakHighFrequencyRef and RmsHighFrequencyRef as reference values and outputs the reference values used in the calculated to PeakHighFrequencyRefCalculated and RmsHighFrequencyRefCalculated.

9.26.7.15.9.1 DataConsistentWithLockedBuffers

Name:

DataConsistentWithLockedBuffers01

If the data buffers on the module are locked to prevent uploading, this bit is used to indicate the time at which all characteristic values and frequency bands are consistent with the locked buffers on the module.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Values |
|-----------|--------|
| BOOL | 0 or 1 |

9.26.7.15.9.2 DataToggleBit

Name:

DataToggleBit01

This bit changes its value whenever new characteristic values are loaded from the module and updated (approximately every 300 ms).

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Values |
|-----------|--------|
| BOOL | 0 or 1 |

9.26.7.15.9.3 OverflowAnalogInput

Name:

OverflowAnalogInput01 to OverflowAnalogInput04

Indicates whether a signal is pending on the input that is greater than the configured "AnalogInputScale" on page 3064.

Information:

This is always based on a 100 mV/g sensor.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Values |
|-----------|--------|
| BOOL | 0 or 1 |

9.26.7.15.9.4 OverflowCharacteristicValues

Name:

OverflowCharacteristicValues01 to OverflowCharacteristicValues04

This register contains an overflow indicator bit for each characteristic value of the respective channel.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|--------------------------|-------|-------------|
| 0 | PeakHighFrequency | 0 | No error |
| | | 1 | Overflow |
| 1 | RmsHighFrequency | 0 | No error |
| | | 1 | Overflow |
| 2 | CrestFactorHighFrequency | 0 | No error |
| | | 1 | Overflow |
| 3 | Vdi3832KtHighFrequency | 0 | No error |
| | | 1 | Overflow |
| 4 | RmsAccEnvelope | 0 | No error |
| | | 1 | Overflow |
| 5 | RmsVelEnvelope | 0 | No error |
| | | 1 | Overflow |
| 6 | RmsAccRaw | 0 | No error |
| | | 1 | Overflow |
| 7 | RmsVelRaw | 0 | No error |
| | | 1 | Overflow |
| 8 | PeakRaw | 0 | No error |
| | | 1 | Overflow |
| 9 | CrestFactorRaw | 0 | No error |
| | | 1 | Overflow |
| 10 | SkewnessRaw | 0 | No error |
| | | 1 | Overflow |
| 11 | KurtosisRaw | 0 | No error |
| | | 1 | Overflow |
| 12 | Vdi3832KtRaw | 0 | No error |
| | | 1 | Overflow |
| 13 | Iso10816 | 0 | No error |
| | | 1 | Overflow |
| 14 | RmsRaw | 0 | No error |
| | | 1 | Overflow |
| 15 | Reserved | 0 | |

9.26.7.15.9.5 OverflowFrequencyBands

Name:

OverflowFrequencyBands01

This register contains an overflow indicator bit for each frequency band.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------|-------|-------------|
| 0 | FrequencyBand01 | 0 | No error |
| | | 1 | Overflow |
| ... | ... | ... | ... |
| 31 | FrequencyBand32 | 0 | No error |
| | | 1 | Overflow |

9.26.7.15.9.6 PeakHighFrequencyRef

Name:

PeakHighFrequencyRef01 to PeakHighFrequencyRef04

Reference value (correct state) specified from the application for the peak value of the high-pass filtered input signal used to calculate the Vdi3832 K(t) of the high-pass filtered input signal.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Information |
|-----------|---|
| REAL | Range of values depends on sensor sensitivity |

9.26.7.15.9.7 PeakHighFrequencyRefCalculated

Name:

PeakHighFrequencyRefCalculated01 to PeakHighFrequencyRefCalculated04

Reference value (correct state) used by the module for the absolute maximum of the high-pass filtered input signal used to last calculate the Vdi3832 K(t) of the peak value.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Information |
|-----------|---|
| REAL | Range of values depends on sensor sensitivity |

9.26.7.15.9.8 PeakRawRef

Name:

PeakRawRef01 to PeakRawRef04

Reference value (correct state) specified by the application for the absolute maximum of the raw signal used to calculate Vdi3832 K(t) of the raw signal.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Information |
|-----------|---|
| REAL | Range of values depends on sensor sensitivity |

9.26.7.15.9.9 PeakRawRefCalculated

Name:

PeakRawRefCalculated01 to PeakRawRefCalculated04

Reference value (correct state) used by the module for the absolute maximum of the raw signal used to last calculate the Vdi3832 K(t) of the raw signal.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Information |
|-----------|---|
| REAL | Range of values depends on sensor sensitivity |

9.26.7.15.9.10 RmsHighFrequencyRef

Name:

RmsHighFrequencyRef01 to RmsHighFrequencyRef04

Reference value (correct state) specified from the application for the RMS value of the high-pass filtered input signal used to calculate the Vdi3832 K(t) of the high-pass filtered input signal.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Information |
|-----------|---|
| REAL | Range of values depends on sensor sensitivity |

9.26.7.15.9.11 RmsHighFrequencyRefCalculated

Name:

RmsHighFrequencyRefCalculated01 to RmsHighFrequencyRefCalculated04

Reference value (correct state) used by the module for the RMS value of the high-pass filtered input signal used to last calculate the Vdi3832 K(t) of the high-pass filtered input signal.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Information |
|-----------|---|
| REAL | Range of values depends on sensor sensitivity |

9.26.7.15.9.12 RmsRawRef

Name:

RmsRawRef01 to RmsRawRef04

Reference value (correct state) specified by the application for the RMS value of the raw signal used to calculate Vdi3832 K(t) of the raw signal.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Information |
|-----------|---|
| REAL | Range of values depends on sensor sensitivity |

9.26.7.15.9.13 RmsRawRefCalculated

Name:

RmsRawRefCalculated01 to RmsRawRefCalculated04

Reference value (correct state) used by the module for the RMS value of the raw signal used to last calculate the Vdi3832 K(t) of the raw signal.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Information |
|-----------|---|
| REAL | Range of values depends on sensor sensitivity |

9.26.7.15.9.14 SensitivitySensor

Name:

SensitivitySensor01 to SensitivitySensor04

The module always calculates the characteristic values based on a 100 mV/g sensor on the input. If using a different sensor, the sensor sensitivity can be specified in mV/g for each channel on these registers. All cyclic characteristic values are then automatically scaled to the correct sensor resolution by Automation Runtime. If this parameter is changed, then the next measurement indicated by "[DataToggleBit](#)" on [page 3066](#) is invalid.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Data type | Information |
|-----------|---|
| REAL | Range of values depends on sensor sensitivity |

9.26.7.15.10 Characteristic values

The following applies to all characteristic value module registers:

- These registers are only available in [Function model 2 - Slow master](#) and [Function model 254 - Bus controller](#).
- All calculated characteristic values can be locked using RequestDataLock01, which allows all registers to be read in a consistent manner.

The following characteristic values can be read from the X20CM4810 module for each channel:

| Characteristic values | Description |
|---|---|
| PeakHighFrequency | Absolute maximum of the high-pass filtered input signal. |
| CrestFactorHighFrequency¹⁾ | Ratio of the absolute maximum to the RMS value of the high-pass filtered input signal |
| Vdi3832KtHighFrequency¹⁾ | Ratio between the reference values and the currently measured values of the high-pass filtered input signal in accordance with the VDI 3832 guideline |
| PeakRaw | Peak value (absolute) of the input signal up to the configured maximum frequency |
| CrestFactorRaw | Ratio of the absolute maximum to the RMS value of the input signal up to the configured maximum frequency |
| SkewnessRaw | Skewness (third statistical moment) of the input signal up to the configured maximum frequency |
| KurtosisRaw | Kurtosis (fourth statistical moment) of the input signal up to the configured maximum frequency |
| Vdi3832KtRaw¹⁾ | Ratio between the reference values and the currently measured values of the input signal in accordance with the VDI 3832 guideline |
| RmsHighFrequency | RMS value of the high-pass filtered input signal |
| RmsRaw | RMS value of the input signal up to the configured maximum frequency |
| RmsAccRaw | RMS value of the input signal's acceleration from the configured minimum frequency up to the configured maximum frequency |
| RmsVelRaw | RMS value of the input signal's speed from the configured minimum frequency up to the configured maximum frequency ²⁾ |
| Iso10816 | RMS value of the velocity in the frequency domain 10 Hz to 1 kHz in accordance with ISO 10816 |
| RmsAccEnvelope | RMS value of the acceleration of the input signal's envelope from the configured minimum frequency up to the configured maximum frequency |
| RmsVelEnvelope | RMS value of the speed of the input signal's envelope from the configured minimum frequency up to the configured maximum frequency ²⁾ |

1) Only in [Function model 0 - Standard](#)

2) Only calculated if the EnableVelocityCalculation bit (configured in the "[SensorConfig](#)" on [page 3058](#) register) of the respective channel is set; otherwise, 0 is output.

9.26.7.15.10.1 Sum of maximum value

The maximum value is often also referred to as the peak value.

The peak value of a mechanical oscillation signal indicate the maximum sum of individual impacts that come from the ambient noise. Different types of damage give rise to strong impacts, which show up in the peak value.

PeakHighFrequency

Name:

PeakHighFrequency01 to PeakHighFrequency04

Registers for reading the absolute maximum of the high-pass filtered input signal of the respective channel.

PeakHighFrequency is formed from the high-pass filtered input signal of the oscillation acceleration in the frequency domain between the value set in register "[HighFrequencyConfig](#)" on page 3085 and 10 kHz.

Characteristic value in [Function model 0 - Standard](#)

| Format | Unit | Value on overflow |
|--------|------|-------------------|
| REAL | mg | 256000.0 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 1/65536 g | 16777215 |

PeakRaw

Name:

PeakRaw01 to PeakRaw04

Registers for reading the absolute maximum of the raw signal of the respective channel.

PeakRaw is formed from the raw signal of the oscillation acceleration up to the maximum frequency configured in register "[MaxFrequencyRaw](#)" on page 3086.

Characteristic value in [Function model 0 - Standard](#)

| Format | Unit | Value on overflow |
|--------|------|-------------------|
| REAL | mg | 256000.0 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 1/65536 g | 16777215 |

9.26.7.15.10.2 RMS value

The RMS value is also known as the quadratic mean, or the root-mean-square. Along with the amplitude, it also takes the energy content of the oscillation into consideration and is the mathematical background for many characteristic values of assessment.

If the RMS is calculated to be above the oscillation velocity, this can be referred to as oscillation speed. In the RMS value, everything contributing to the oscillation is added up. The high oscillation amplitudes of an imbalance are the same as the low oscillation level of bearing damage that is just beginning to occur.

If the RMS value is measured broadly, changes in individual elements contributing to the oscillation can be masked by the averaging. The ability to detect damage early, e.g. due to defects in roller bearings, is limited.

Iso10816

Name:

Iso10816_01 to Iso10816_04

Registers for reading the RMS value (per ISO 10816) of the respective channel.

Iso10816 is formed from the raw signal of the oscillation velocity in a frequency range from 10 Hz to 1 kHz.

This broad characteristic value is often used in the assessment of the machine condition since assessment limits are specified for this characteristic value in the standard. These depend on the type of machine and type of installation (rigid or elastic). The characteristic value limits for a pre-warning or a warning are given according to their defined classification.

Figure 199: ISO assessment scheme

If the machine condition is in order, this characteristic value is low. If damage occurs, then this value increases severely. If the RMS is assessed in the range of the oscillation velocity, lower frequency portions such as drive speed (and associated imbalance and/or misalignment) that are emphasized more and reflected more heavily in the characteristic value.

Characteristic value in [Function model 0 - Standard](#)

| Format | Unit | Value on overflow |
|--------|------|-------------------|
| REAL | mm/s | 16777.21 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 0.001 mm/s | 16777215 |

RmsAccEnvelope

Name:

RmsAccEnvelope01 to RmsAccEnvelope04

Registers for reading the RMS value of the envelope signal of the respective channel.

RmsAccEnvelope is formed from the envelope signal of the oscillation acceleration from the configured minimum frequency ("[MinFrequencyEnvelope](#)" on page 3087) to the configured maximum frequency ("[MaxFrequencyEnvelope](#)" on page 3085).

Characteristic value in [Function model 0 - Standard](#)

| Format | Unit | Value on overflow |
|--------|------|-------------------|
| REAL | mg | 1.677722E+7 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 0.001 g | 16777215 |

RmsAccRaw

Name:

RmsAccRaw01 to RmsAccRaw04

Registers for reading the acceleration RMS value of the respective channel.

RmsAccRaw is formed from the raw signal of the oscillation acceleration from the configured minimum frequency ("[MinFrequencyRaw](#)" on page 3088) to the configured maximum frequency ("[MaxFrequencyRaw](#)" on page 3086).

Characteristic value in [Function model 0 - Standard](#)

| Format | Unit | Value on overflow |
|--------|------|-------------------|
| REAL | mg | 1.677722E+7 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 0.001 g | 16777215 |

RmsHighFrequency

Name:

RmsHighFrequency01 to RmsHighFrequency04

Registers for reading the high-pass RMS value of the respective channel.

RmsHighFrequency is formed from the high-pass filtered input signal of the oscillation acceleration in the frequency domain between the value set in register "[HighFrequencyConfig](#)" on page 3085 and 10 kHz.

Characteristic value in [Function model 0 - Standard](#)

| Format | Unit | Unit on overflow |

| REAL | mg | 256000.0 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 1/65536 g | 16777215 |

RmsRaw

Name:

RmsRaw01 to RmsRaw04

Registers for reading the raw signal RMS value of the respective channel.

RmsRaw is formed from the raw signal of the oscillation acceleration up to the maximum frequency configured in register "[MaxFrequencyRaw](#)" on page 3086.Characteristic value in [Function model 0 - Standard](#)

| Format | Unit | Value on overflow |
|--------|------|-------------------|
| REAL | mg | 256000.0 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 1/65536 g | 16777215 |

RmsVelEnvelope

Name:

RmsVelEnvelope01 to RmsVelEnvelope04

Registers for reading the RMS value of the envelope velocity of the respective channel.

RmsVelEnvelope is formed from the envelope signal of the oscillation acceleration from the configured minimum frequency ("[MinFrequencyEnvelope](#)" on page 3087) to the configured maximum frequency ("[MaxFrequencyEnvelope](#)" on page 3085).This characteristic value is only calculated if the EnableVelocityCalculation bit (configuration in register "[Sensor-Config](#)" on page 3058) is set for the respective channel; otherwise, 0 is output.Characteristic value in [Function model 0 - Standard](#)

| Format | Unit | Value on overflow |
|--------|------|-------------------|
| REAL | mm/s | 16777.21 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 0.001 mm/s | 16777215 |

RmsVelRaw

Name:

RmsVelRaw01 to RmsVelRaw04

Registers for reading the velocity RMS value of the respective channel.

RmsVelRaw is formed from the raw signal of the oscillation velocity from the configured minimum frequency ("[MinFrequencyRaw](#)" on page 3088) to the configured maximum frequency ("[MaxFrequencyRaw](#)" on page 3086).This characteristic value is only calculated if the EnableVelocityCalculation bit (configuration in register "[Sensor-Config](#)" on page 3058) is set for the respective channel; otherwise, 0 is output.Characteristic value in [Function model 0 - Standard](#)

| Format | Unit | Value on overflow |
|--------|------|-------------------|
| REAL | mm/s | 16777.21 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 0.001 mm/s | 16777215 |

9.26.7.15.10.3 Crest factor

The crest factor is defined as the quotient derived from the peak value and the RMS value. In a sinusoidal oscillation, this factor amounts to $\sqrt{2}$. This value is also known in electrical engineering as the crest factor.

In a bearing that is operating normally, the crest factor is also approximately the value $\sqrt{2}$. If the condition of the bearing deteriorates, individual impacts affect the peak value and consequently raise the crest factor. If pronounced defects are then compounded by overall wear, the RMS value is increased further. In the worst case, the crest factor can remain unchanged or even sink again, even despite increasing damage.

Figure 200: Relationship between the RMS value and peak value

Information:

When a recording of the crest factor is made, the peak and RMS values should also be recorded.

CrestFactorHighFrequency

Name:

CrestFactorHighFrequency01 to CrestFactorHighFrequency04

Registers for reading the raw value ratio of the absolute maximum ("[PeakHighFrequency](#)" on page 3071) to the RMS value ("[RmsHighFrequency](#)" on page 3073) of the respective channel.

CrestFactorHighFrequency is formed from the high-pass filtered input signal of the oscillation acceleration in the frequency domain between the value set in register "[HighFrequencyConfig](#)" on page 3085 and 10 kHz.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Format | Unit |
|--------|------|
| REAL | 1 |

CrestFactorRaw

Name:

CrestFactorRaw01 to CrestFactorRaw04

Registers for reading the raw value ratio of the absolute maximum to the RMS value of the respective channel.

CrestFactorRaw is formed from the raw signal of the oscillation acceleration up to the maximum frequency configured in register "[MaxFrequencyRaw](#)" on page 3086.

Since this register value is divided by the RMS value in the module ("[RmsRaw](#)" on page 3074), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

Characteristic value in [Function model 0 - Standard](#)

| Format | Unit |
|--------|------|
| REAL | 1 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| UDINT | 0.001 | 16777215 |

9.26.7.15.10.4 K(t) value

The K(t) is described in the VDI 3832 guideline and is calculated from the RMS value and the absolute maximum of a broadband time signal of the oscillation acceleration. For the time signal, the entire available frequency spectrum is used for calculation.

This ratio correlates to the reference values. The reference values should be measured by the operator shortly after the running-in time. These values can be classified as "Plant in order" and are therefore the initial values.

The K(t) value decreases with progressive wear. This allows it to be classified into 3 groups:

- Undamaged
- Early damage
- Pronounced damage

The advantage of the K(t) value is that does not change much, even when damage is severe.

$$K(t) = \frac{a_{\text{RMS}}(0) \cdot a_p(0)}{a_{\text{RMS}}(t) \cdot a_p(t)}$$

The following applies:

| Formula symbols | Explanation | Characteristic value in the module |
|---------------------|--------------------------------------|------------------------------------|
| $a_{\text{rms}}(0)$ | RMS value of the reference value | RmsHighFrequencyRef RmsRawRef |
| $a_p(0)$ | Maximum value of the reference value | PeakHighFrequencyRef PeakRawRef |
| $a_{\text{rms}}(t)$ | Current RMS value | RmsHighFrequency RmsRaw |
| $a_p(t)$ | Current absolute maximum | PeakHighFrequency ReakRaw |

Example

Possible progression of the (K/t) characteristic value

Figure 201: K(t) value progression

Vdi3832KtHighFrequency

Name:

Vdi3832KtHighFrequency01 to Vdi3832KtHighFrequency04

Registers for reading the high-pass K(t) value (per VDI 3832 guideline) of the respective channel.

Vdi3832KtHighFrequency is formed from the peak value ("[PeakHighFrequency](#)" on page 3071) and RMS value ("[RmsHighFrequency](#)" on page 3073) of the high-pass filtered input signal and the vibration acceleration in the frequency range between the value set in register "[HighFrequencyConfig](#)" on page 3085 and 10 kHz.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Format | Unit |
|--------|------|
| REAL | 1 |

Vdi3832KtRaw

Name:

Vdi3832KtRaw01 to Vdi3832KtRaw04

Registers for reading the raw K(t) value (per VDI 3832 guideline) of the respective channel.

Vdi3832KtRaw is formed from the raw signal of the oscillation acceleration up to the maximum frequency configured in register "[MaxFrequencyRaw](#)" on page 3086.

This register is only available in [Function model 0 - Standard](#) in the Automation Studio I/O mapping.

| Format | Unit |
|--------|------|
| REAL | 1 |

9.26.7.15.10.5 Kurtosis

Kurtosis is an effective characteristic value for assessing the number of peaks in a signal. Kurtosis (peakedness, fourth statistical moment) is defined as the ratio of two statistical characteristic values/processes.

Kurtosis is a type of weighted [Crest factor](#). The signal peaks are valued higher than the "signal noise" (also called the carpet value) due to the fourth power of the integral. Not only is the RMS value also used, but the entire signal progression as well. This increases the informational value of this characteristic value.

Information:

The kurtosis factor is standardized at 0 in the module.

A kurtosis factor of less than 2 is typical of a machine in good condition.

KurtosisRaw

Name:

KurtosisRaw01 to KurtosisRaw04

Registers to read the kurtosis factor of the respective channel.

KurtosisRaw is formed from the raw signal of the oscillation acceleration up to the maximum frequency configured in register "[MaxFrequencyRaw](#)" on page 3086.

Since this register value is divided by the RMS value in the module ("[RmsRaw](#)" on page 3074), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

Characteristic value in [Function model 0 - Standard](#)

| Format | Unit |
|--------|------|
| REAL | 1 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| DINT | 0.001 | 8388607 |

9.26.7.15.10.6 Skewness factor

The skewness factor (skewness, third statistical moment) specifies the degree of a signal's asymmetry in reference to its standard distribution. The lower the skewness, the more evenly distributed the signal. A signal with a high skewness factor has many large amplitudes in the assessment range.

A symmetrically distributed signal has a skewness factor of 0. Depending on the direction of the slant, the skewness can be positive or negative. A considerable slant means approximately a skewness factor of ± 1 .

A large kurtosis factor combined with a large skewness factor indicates electrostatic discharge.

SkewnessRaw

Name:

SkewnessRaw01 to SkewnessRaw04

Registers to read the skewness factor of the respective channel.

SkewnessRaw is formed from the raw signal of the oscillation acceleration up to the maximum frequency configured in register "[MaxFrequencyRaw](#)" on page 3086.

Since this register value is divided by the RMS value in the module ("[RmsRaw](#)" on page 3074), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

Characteristic value in [Function model 0 - Standard](#)

| Format | Unit |
|--------|------|
| REAL | 1 |

Characteristic value in all other function models

| Format | Resolution and unit | Value on overflow |
|--------|---------------------|-------------------|
| DINT | 0.001 | 8388607 |

9.26.7.15.10.7 FrequencyBand

Name:

FrequencyBand01 to FrequencyBand32

Registers for reading the respective frequency band.

If the frequency band is configured to a velocity signal, this value is only calculated if bit EnableVelocityCalculation (configuration in register "[SensorConfig](#)" on page 3058) of the corresponding channel is set; otherwise, 0 is output.

For more information, see "[Frequency bands](#)" on page 3055.

| Format | Resolution and unit | Value on overflow |
|-----------------|---|-------------------|
| 24-bit unsigned | 0.001 g or 0.001 mm/s Depends on the configuration | 16777215 |
| 24-bit unsigned | 1/65536 g or 1/65536 mm/s Depends on the configuration | 16777215 |

Parameter after preparation by Automation Runtime in [Function model 0 - Standard](#)

| Format | Unit |
|--------|---|
| REAL | mg or mm/s depending on the configuration |

9.26.7.15.11 Characteristic values (minimum and maximum)

The module's characteristic values are recalculated every 300 ms. To prevent values from being lost, it is necessary to collect this data quickly enough. If this is not possible, the characteristic values on the module can be locked using data point RequestDataLock01 and then read acyclically in [Function model 2 - Slow master](#) and [Function model 254 - Bus controller](#). However, measurements are lost.

To prevent measurements from being lost, a special function has been implemented in the module that records the minimum and maximum values of all characteristic values calculated in the module. With each edge of bit MinMayUpdate01 in register "Control" on [page 3057](#), a new measurement can be started whereby the minimum and maximum values are reinitialized. Simultaneously, the current data is copied to the acyclic registers.

The number of collected measurements can then be read using acyclic register "MinMaxCounter" on [page 3081](#). The respective values are read using the acyclic minimum and maximum registers.

Example

For Iso10816, these are the Iso10816Min01-04 and Iso10816Max01-04 registers.

Information:

- If data is locked with RequestDataLock01, no further measured values are collected. This only affects [Function model 2 - Slow master](#) and [Function model 254 - Bus controller](#) since the characteristic values are not locked in the standard function model.
- If a characteristic value overflow or open circuit occurs, no new values are collected.
- The minimum and maximum registers are each initialized using the maximum and minimum of the respective data type. If there is no valid value on the characteristic value for the overall measurement, then the initial value is retained (e.g. on overflow, open circuit or locked data).
- If the data on the module is frozen (DataLockValid01 = 1), no new values are included in the minimum formation, but the measurement cycles are still counted.

The registers are only updated on an edge of "MinMaxUpdate01" on [page 3057](#) and only valid if "MinMaxCounter" on [page 3081](#) is not equal to 0. Register "MinMaxCounter" on [page 3081](#) specifies the number of collected measurement cycles for the minimum and maximum.

9.26.7.15.11.1 CrestFactorRawMax

Name:

CrestFactorRawMax01 to CrestFactorRawMax04

Maximum value of the "CrestFactorRaw" on page 3075 characteristic value of the respective channel in 1/1000.

Since this register value is divided by the RMS value in the module ("RmsRaw" on page 3074), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.2 CrestFactorRawMin

Name:

CrestFactorRawMin01 to CrestFactorRawMin04

Minimum value of the "CrestFactorRaw" on page 3075 characteristic value of the respective channel in 1/1000.

Since this register value is divided by the RMS value in the module ("RmsRaw" on page 3074), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.3 Iso10816Max

Name:

Iso10816Max01 to Iso10816Max04

Maximum value of the "Iso10816" on page 3072 characteristic value of the respective channel in 1/1000 mm/s.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.4 Iso10816Min

Name:

Iso10816Min01 to Iso10816Min04

Minimum value of the "Iso10816" on page 3072 characteristic value of the respective channel in 1/1000 mm/s.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.5 KurtosisRawMax

Name:

KurtosisRawMax01 to KurtosisRawMax04

Maximum value of the "KurtosisRaw" on page 3077 characteristic value of the respective channel in 1/1000.

Since this register value is divided by the RMS value in the module ("RmsRaw" on page 3074), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

9.26.7.15.11.6 KurtosisRawMin

Name:

KurtosisRawMin01 to KurtosisRawMin04

Minimum value of the "[KurtosisRaw](#)" on page 3077 characteristic value of the respective channel in 1/1000.

Since this register value is divided by the RMS value in the module ("[RmsRaw](#)" on page 3074), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also "[Characteristic values \(minimum and maximum\)](#)" on page 3079 for additional information.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

9.26.7.15.11.7 MinMaxCounter

Name:

MinMaxCounter01

This register specifies how many measurements were collected the last time the minimum and maximum were determined. It is only updated when an edge occurs for MinMaxUpdate01. If the MinMaxUpdate01 bit is not toggled after 65535 measurements, then the counter is limited to 65535. However, the minimum and maximum formation continues. All acyclic minimum and maximum values are only valid if "[MinMaxCounter](#)" on page 3081 is not equal to 0.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.11.8 PeakHighFrequencyMax

Name:

PeakHighFrequencyMax01 to PeakHighFrequencyMax04

Maximum value of the "[PeakHighFrequency](#)" on page 3071 characteristic value of the respective channel in 1/65536 g.

See also "[Characteristic values \(minimum and maximum\)](#)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.9 PeakHighFrequencyMin

Name:

PeakHighFrequencyMin01 to PeakHighFrequencyMin04

Minimum value of the "[PeakHighFrequency](#)" on page 3071 characteristic value of the respective channel in 1/65536 g.

See also "[Characteristic values \(minimum and maximum\)](#)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.10 PeakRawMax

Name:

PeakRawMax01 to PeakRawMax04

Maximum value of the "[PeakRaw](#)" on page 3071 characteristic value of the respective channel in 1/65536 g.

See also "[Characteristic values \(minimum and maximum\)](#)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.11 PeakRawMin

Name:

PeakRawMin01 to PeakRawMin04

Minimum value of the "PeakRaw" on page 3071 characteristic value of the respective channel in 1/65536 g.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.12 RmsAccEnvelopeMax

Name:

RmsAccEnvelopeMax01 to RmsAccEnvelopeMax04

Maximum value of the "RmsAccEnvelope" on page 3073 characteristic value of the respective channel in 1/1000 g.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.13 RmsAccEnvelopeMin

Name:

RmsAccEnvelopeMin01 to RmsAccEnvelopeMin04

Minimum value of the "RmsAccEnvelope" on page 3073 characteristic value of the respective channel in 1/1000 g.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.14 RmsAccRawMax

Name:

RmsAccRawMax01 to RmsAccRawMax04

Maximum value of the "RmsAccRaw" on page 3073 characteristic value of the respective channel in 1/1000 g.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.15 RmsAccRawMin

Name:

RmsAccRawMin01 to RmsAccRawMin04

Minimum value of the "RmsAccRaw" on page 3073 characteristic value of the respective channel in 1/1000 g.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.16 RmsHighFrequencyMax

Name:

RmsHighFrequencyMax01 to RmsHighFrequencyMax04

Maximum value of the "RmsHighFrequency" on page 3073 characteristic value of the respective channel in 1/65536 g.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.17 RmsHighFrequencyMin

Name:

RmsHighFrequencyMin01 to RmsHighFrequencyMin04

Minimum value of the "PeakHighFrequency" on page 3071 characteristic value of the respective channel in 1/65536 g.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.18 RmsRawMax

Name:

RmsRawMax01 to RmsRawMax04

Maximum value of the "RmsRaw" on page 3074 characteristic value of the respective channel in 1/65536 g.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.19 RmsRawMin

Name:

RmsRawMin01 to RmsRawMin04

Minimum value of the "RmsRaw" on page 3074 characteristic value of the respective channel in 1/65536 g.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.20 RmsVelEnvelopeMax

Name:

RmsVelEnvelopeMax01 to RmsVelEnvelopeMax04

Maximum value of the "RmsVelEnvelope" on page 3074 characteristic value of the respective channel in 1/1000 mm/s.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

This value is only calculated if the EnableVelocityCalculation bit (configuration in register "SensorConfig" on page 3058) is set for the respective channel; otherwise, 0 is output.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.21 RmsVelEnvelopeMin

Name:

RmsVelEnvelopeMin01 to RmsVelEnvelopeMin04

Minimum value of the "RmsVelEnvelope" on page 3074 characteristic value of the respective channel in 1/1000 mm/s.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

This value is only calculated if the EnableVelocityCalculation bit (configuration in register "SensorConfig" on page 3058) is set for the respective channel; otherwise, 0 is output.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.22 RmsVelRawMin

Name:

RmsVelRawMin01 to RmsVelRawMin04

Minimum value of the "RmsVelRaw" on page 3074 characteristic value of the respective channel in 1/1000 mm/s.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

This value is only calculated if the EnableVelocityCalculation bit (configuration in register "SensorConfig" on page 3058) is set for the respective channel; otherwise, 0 is output.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.23 RmsVelRawMax

Name:

RmsVelRawMax01 to RmsVelRawMax04

Maximum value of the "RmsVelRaw" on page 3074 characteristic value of the respective channel in 1/1000 mm/s.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

This value is only calculated if the EnableVelocityCalculation bit (configuration in register "SensorConfig" on page 3058) is set for the respective channel; otherwise, 0 is output.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.11.24 SkewnessRawMax

Name:

SkewnessRawMax01 to SkewnessRawMax04

Maximum value of the "SkewnessRaw" on page 3078 characteristic value of the respective channel in 1/1000.

Since this register value is divided by the RMS value in the module ("RmsRaw" on page 3074), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

9.26.7.15.11.25 SkewnessRawMin

Name:

SkewnessRawMin01 to SkewnessRawMin04

Minimum value of the "SkewnessRaw" on page 3078 characteristic value of the respective channel in 1/1000.

Since this register value is divided by the RMS value in the module ("RmsRaw" on page 3074), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also "Characteristic values (minimum and maximum)" on page 3079 for additional information.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

9.26.7.15.12 Frequency band configuration registers

9.26.7.15.12.1 HighFrequencyConfig

Name:

HighFrequencyConfig01

Register for defining the envelope signal high-pass and characteristic values "[PeakHighFrequency](#)" on page 3071 and "[RmsHighFrequency](#)" on page 3073. This setting applies to the entire module.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| UINT | See bit structure. | 1 |

Bit structure:

| Bit | Description | Values | Information |
|--------|---|---------|--|
| 0 - 3 | High-pass configuration for the entire module | 0 | 2000 Hz |
| | | 1 | 1000 Hz (bus controller default setting) |
| | | 2 | 500 Hz |
| | | 3 to 15 | Invalid |
| 4 - 15 | Reserved | - | |

9.26.7.15.12.2 HighFrequencyConfigRead

Name:

HighFrequencyConfig01Read

Register for reading the envelope signal high-pass and characteristic values "[PeakHighFrequency](#)" on page 3071 and "[RmsHighFrequency](#)" on page 3073.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.12.3 MaxFrequencyEnvelope

Name:

MaxFrequencyEnvelope01

Registers for setting the maximum frequency of the channel. Reducing the maximum frequency allows the frequency resolution in the spectrum to be increased.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|---------------------------------|---------|--|
| 0 - 3 | Maximum frequency for channel 1 | 0 | 2000 Hz (bus controller default setting) |
| | | 1 | 1000 Hz |
| | | 2 | 500 Hz |
| | | 3 | 200 Hz |
| | | 4 to 15 | Invalid |
| 4 - 7 | Maximum frequency for channel 2 | x | For possible values, see channel 1. |
| 8 - 11 | Maximum frequency for channel 3 | x | For possible values, see channel 1. |
| 12 - 15 | Maximum frequency for channel 4 | x | For possible values, see channel 1. |

Overview of the maximum frequency of the envelope signal

| Maximum frequency | Sampling frequency | Duration of measurement | Frequency resolution in the frequency spectrum |
|-------------------|--------------------|-------------------------|--|
| 2000 Hz | 5156 Hz | 1.5888 s | 0.6294 Hz |
| 1000 Hz | 2578 Hz | 3.1775 s | 0.3147 Hz |
| 500 Hz | 1289 Hz | 6.3550 s | 0.1574 Hz |
| 200 Hz | 516 Hz | 15.8875 s | 0.0629 Hz |

Important information for configuring the maximum frequency

- The frequency range must be larger than the damage frequency but should otherwise be kept as small as possible in order to achieve a good resolution.
- When using broadband values (e.g. [PeakRaw](#)), only the largest peak value is returned during a measurement. Using a longer measurement time at a lower frequency can lead to the measured value being overlooked in some applications.
- The maximum frequency influences the size of the sampling rate and can be configured using register "[AnalogInput](#)" on page 3065.

9.26.7.15.12.4 MaxFrequencyEnvelopeRead

Name:

MaxFrequencyEnvelope01Read

This register is used to read the configured maximum frequency for the individual channels' envelope signal.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.12.5 MaxFrequencyRaw

Name:

MaxFrequencyRaw01

Registers for setting the maximum frequency of the channel. Reducing the maximum frequency allows the frequency resolution in the spectrum to be increased.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| UINT | See bit structure. | 8738 |

Bit structure:

| Bit | Description | Value | Information |
|---------|---------------------------------|---------|--|
| 0 - 3 | Maximum frequency for channel 1 | 0 | 10000 Hz |
| | | 1 | 5000 Hz |
| | | 2 | 2000 Hz (bus controller default setting) |
| | | 3 | 1000 Hz |
| | | 4 | 500 Hz |
| | | 5 | 200 Hz |
| 6 to 15 | | Invalid | |
| 4 - 7 | Maximum frequency for channel 2 | x | For possible values, see channel 1. |
| 8 - 11 | Maximum frequency for channel 3 | x | For possible values, see channel 1. |
| 12 - 15 | Maximum frequency for channel 4 | x | For possible values, see channel 1. |

Overview of the maximum frequency of the raw signal

| Maximum frequency | Sampling frequency | Duration of measurement | Frequency resolution in the frequency spectrum |
|-------------------|--------------------|-------------------------|--|
| 10000 Hz | 25781 Hz | 0.3178 s | 3.1471 Hz |
| 5000 Hz | 12891 Hz | 0.6355 s | 1.5736 Hz |
| 2000 Hz | 5156 Hz | 1.5888 s | 0.6294 Hz |
| 1000 Hz | 2578 Hz | 3.1775 s | 0.3147 Hz |
| 500 Hz | 1289 Hz | 6.3550 s | 0.1574 Hz |
| 200 Hz | 516 Hz | 15.8875 s | 0.0629 Hz |

Important information for configuring the maximum frequency

- The frequency range must be larger than the damage frequency but should otherwise be kept as small as possible in order to achieve a good resolution.
- When using broadband values (e.g. PeakRaw), only the largest peak value is returned during a measurement. Using a longer measurement time at a lower frequency can lead to the measured value being overlooked in some applications.
- The maximum frequency influences the size of the sampling rate and can be configured using register "[AnalogInput](#)" on page 3065.

9.26.7.15.12.6 MaxFrequencyRawRead

Name:

MaxFrequencyRaw01Read

This register is used to read the configured maximum frequency for the raw signal of individual channels.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.12.7 MinFrequencyEnvelope

Name:

MinFrequencyEnvelope01

This register is used to configure the lowest frequency of the envelope signal to be evaluated for the individual channels.

This configuration only needs to be set for channels whose EnableVelocityCalculation bit has been set (configured in the "SensorConfig" on page 3058 register).

Bit EnableVelocityCalculation = 0

The following minimum values based on the maximum frequency ("MaxFrequencyEnvelope" on page 3085) are used: This table shows the minimum MinFrequencyEnvelope based on MaxFrequencyEnvelope:

| Maximum frequency | Frequency resolution in the frequency spectrum | Minimum frequency |
|-------------------|--|-------------------|
| 2000 Hz | 0.6294 Hz | 1.888 Hz |
| 1000 Hz | 0.3147 Hz | 0.944 Hz |
| 500 Hz | 0.1574 Hz | 0.472 Hz |
| 200 Hz | 0.0629 Hz | 0.188 Hz |

Bit EnableVelocityCalculation = 1

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|--------------------------------|---------|--|
| 0 - 3 | Lowest frequency for channel 1 | 0 | 10 Hz (bus controller default setting) |
| | | 1 | 5 Hz |
| | | 2 | 2 Hz |
| | | 3 | 1 Hz |
| | | 4 | 0.5 Hz |
| | | 5 to 15 | Invalid |
| 4 - 7 | Lowest frequency for channel 2 | x | For possible values, see channel 1. |
| 8 - 11 | Lowest frequency for channel 3 | x | For possible values, see channel 1. |
| 12 - 15 | Lowest frequency for channel 4 | x | For possible values, see channel 1. |

Information:

If a channel's frequency is set lower than the minimum frequency, then the channel will be limited to this lower frequency.

9.26.7.15.12.8 MinFrequencyEnvelopeRead

Name:

MinFrequencyEnvelope01Read

This register is used to read the lowest frequency of the envelope signal to be evaluated for the individual channels.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--------------------------------|---------|-------------------------------------|
| 0 - 3 | Lowest frequency for channel 1 | 0 | 10 Hz |
| | | 1 | 5 Hz |
| | | 2 | 2 Hz |
| | | 3 | 1 Hz |
| | | 4 | 0.5 Hz |
| | | 5 to 14 | Invalid |
| | | 15 | Limited to lowest frequency |
| 4 - 7 | Lowest frequency for channel 2 | x | For possible values, see channel 1. |
| 8 - 11 | Lowest frequency for channel 3 | x | For possible values, see channel 1. |
| 12 - 15 | Lowest frequency for channel 4 | x | For possible values, see channel 1. |

9.26.7.15.12.9 MinFrequencyRaw

Name:

MinFrequencyRaw01

This register is used to configure the lowest frequency of the raw signal to be evaluated for the individual channels.

This configuration only needs to be set for channels whose EnableVelocityCalculation bit has been set (configured in the "SensorConfig" on page 3058 register).

Bit EnableVelocityCalculation = 0

The following minimum values based on the maximum frequency ("MaxFrequencyRaw" on page 3086) are used: This table shows the minimum MinFrequencyRaw based on MaxFrequencyRaw:

| Maximum frequency | Frequency resolution in the frequency spectrum | Minimum frequency |
|-------------------|--|-------------------|
| 10000 Hz | 3.1471 Hz | 9.441 Hz |
| 5000 Hz | 1.5736 Hz | 4.720 Hz |
| 2000 Hz | 0.6294 Hz | 1.888 Hz |
| 1000 Hz | 0.3147 Hz | 0.944 Hz |
| 500 Hz | 0.1574 Hz | 0.472 Hz |
| 200 Hz | 0.0629 Hz | 0.188 Hz |

Bit EnableVelocityCalculation = 1

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|--------------------------------|---------|--|
| 0 - 3 | Lowest frequency for channel 1 | 0 | 10 Hz (bus controller default setting) |
| | | 1 | 5 Hz |
| | | 2 | 2 Hz |
| | | 3 | 1 Hz |
| | | 4 | 0.5 Hz |
| | | 5 to 15 | Invalid |
| 4 - 7 | Lowest frequency for channel 2 | x | For possible values, see channel 1. |
| 8 - 11 | Lowest frequency for channel 3 | x | For possible values, see channel 1. |
| 12 - 15 | Lowest frequency for channel 4 | x | For possible values, see channel 1. |

Information:

If a channel's frequency is set lower than the minimum frequency, then the channel will be limited to this lower frequency.

9.26.7.15.12.10 MinFrequencyRawRead

Name: MinFrequencyRaw01Read

This register is used to configure the lowest frequency of the raw signal to be evaluated for the individual channels.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--------------------------------|---------|-------------------------------------|
| 0 - 3 | Lowest frequency for channel 1 | 0 | 10 Hz |
| | | 1 | 5 Hz |
| | | 2 | 2 Hz |
| | | 3 | 1 Hz |
| | | 4 | 0.5 Hz |
| | | 5 to 14 | Invalid |
| | | 15 | Limited to lowest frequency |
| 4 - 7 | Lowest frequency for channel 2 | x | For possible values, see channel 1. |
| 8 - 11 | Lowest frequency for channel 3 | x | For possible values, see channel 1. |
| 12 - 15 | Lowest frequency for channel 4 | x | For possible values, see channel 1. |

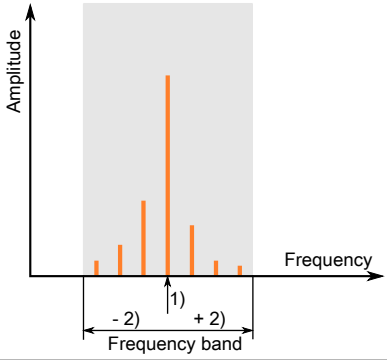

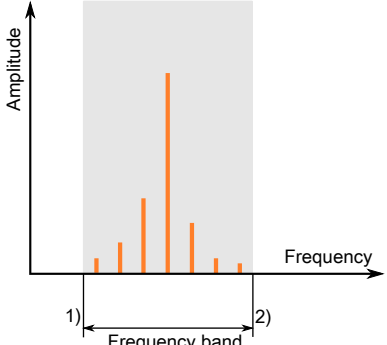

9.26.7.15.13 Frequency bands

For the early detection of damage and problems, it is often useful to monitor individual frequency bands. A selective RMS value can be used as the characteristic value for these frequency bands.

Possibilities:

- "Broadband RMS value" on page 3091
- "Speed-dependent RMS value" on page 3092
- "Noise" on page 3092

Up to 32 different frequency bands can be defined. It is important to note that the format varies slightly depending on the configuration.

| Speed-dependent RMS value | |
|--|--|
|  | <p>Frequency broadband is formed from the speed frequency \pm the frequency interval.</p> <ol style="list-style-type: none"> 1) Speed frequency: $\text{FrequencyBand} \times \text{DmgFreq60Rpm} * \text{ActSpeed}$ 2) Frequency interval: $\text{FrequencyBandTolerance}$ |
| Speed-independent RMS value | |
|  | <p>Frequency bandwidth is formed of the lower and upper frequency band limits.</p> <ol style="list-style-type: none"> 1) Lower frequency band limit: $\text{FrequencyBandLowerFrequency}$ 2) Upper frequency band limit: $\text{FrequencyBandUpperFrequency}$ |

Restricting the frequency range allows certain errors to be identified easily.

One example of this is imbalance. This is clearly shown by an increase in the frequency line for speed. Forming a selective characteristic value for the speed frequency can thus improve classification.

Selective characteristic values can also be formed for RMS values formed from the envelope.

Damage to the outer ring is shown more clearly in the increase of the frequency known as the bearing damage frequency. Damage to the outer ring is shown in the increase of the component of the outer ring damage frequency. This bearing damage frequency is generally available from the bearing manufacturer.

Figure 202: Selective characteristic value for outer ring damage

By configuring a characteristic value with a frequency range around the damage frequency, rolling bearing damage to the outer ring can be detected at an early stage.

If frequencies are entered that are outside the minimum and maximum signal frequency for the selected channel, then only the domains between the minimum and maximum frequency will be analyzed.

Figure 203: Restricting the frequency band evaluation

The two neighboring lines (samples) in the spectrum that are already outside the set window (one above and one below the window) will be partially included in the calculation depending on their distance from the window.

Figure 204: Partial inclusion of marginal lines in the calculation

9.26.7.15.13.1 Broadband RMS value

In this configuration, the RMS value of the configured signal and channel in the frequency band is calculated. The value is calculated from the configured minimum frequency ("[FrequencyBandXXLowerFrequency](#)" on page 3095) to the configured maximum frequency ("[FrequencyBandXXUpperFrequency](#)" on page 3096). The minimum and maximum frequency can be entered here in increments of 0.25 Hz.

Any channel for any frequency band can be selected. The following signals can be selected for each channel:

- Raw acceleration signal
- Raw velocity signal. Equal to 0 if the speed calculation is disabled.
- Enveloped acceleration signal
- Enveloped velocity signal. Equal to 0 if the speed calculation is disabled.

The harmonic frequencies (integer multiples) of the window can also be included in the calculation. Here, the width of the window is simply retained and the mean frequency of the window is multiplied (by 1, 2, 3, etc.) until the maximum frequency of the configured signal and channel is reached.

9.26.7.15.13.2 Speed-dependent RMS value

In this configuration, the RMS value is calculated in a movable window. There are 4 speed inputs available for this (see "ActSpeed" on page 3056 register). One of the 4 speeds can be selected for each of the 32 frequency bands. In addition, the standardized damage frequency at 60 rpm ("FrequencyBandXXDmgFreq60rpm" on page 3095) and a tolerance ("FrequencyBandXXTolerance" on page 3095) must be configured. These can be configured separately for each frequency band.

The window in which the RMS value is calculated is determined as follows:

Minimum frequency = (speed * standardized damage frequency at 60 rpm) - tolerance

Maximum frequency = (speed * standardized damage frequency at 60 rpm) + tolerance

The standardized damage frequency and tolerance can be entered here in increments of 0.01 Hz.

The following signals can be selected for each channel:

- Raw acceleration signal
- Raw velocity signal. Equal to 0 if the speed calculation is disabled.
- Enveloped acceleration signal
- Enveloped velocity signal. Equal to 0 if the speed calculation is disabled.

The harmonic frequencies (integer multiples) of the window can also be included in the calculation. Here, the width of the window is simply retained and the mean frequency of the window is multiplied (by *1, *2, *3, etc.) until the maximum frequency of the set signal and channel is reached.

Information:

If a fixed frequency band is needed in which the minimum frequency ("FrequencyBandXXLowerFrequency" on page 3095) and maximum frequency ("FrequencyBandXXUpperFrequency" on page 3096) must be set with a higher precision than 0.25 Hz, then a speed-dependent frequency band with a fixed speed can be used.

9.26.7.15.13.3 Noise

In this configuration, the noise from a quadrant of the respective signal on the selected channel that is within the frequency band is calculated.

To do this, the configured maximum frequency (registers "MaxFrequencyEnvelope" on page 3085 and "MaxFrequencyRaw" on page 3086) of the signal on the selected channel is divided by 4. This results in 4 quadrants. The configuration can then be used to select one of the 4 quadrants in which the noise should be determined.

The following signals can be selected for each channel:

- Raw acceleration signal
- Raw velocity signal. Equal to 0 if the speed calculation is disabled.
- Enveloped acceleration signal
- Enveloped velocity signal. Equal to 0 if the speed calculation is disabled.

This configuration allows slippage to be effectively measured, for example. The higher the friction, the more noise that is created.

9.26.7.15.13.4 Configuration

Each of the 32 frequency bands can be configured to one of the following characteristic values.

| Characteristic value | Description |
|-------------------------------|--|
| FrequencyBandRmsAccEnvelope | The RMS value formed from the envelope signal of the oscillation acceleration in a freely selectable frequency range. |
| FrequencyBandRmsVelEnvelope | The RMS value formed from the envelope signal of the oscillation acceleration in a freely selectable frequency range. This frequency band is only calculated if the EnableVelocityCalculation bit (configuration in register "SensorConfig" on page 3058) is set for the respective channel; otherwise, 0 is output. |
| FrequencyBandRmsAccRaw | The RMS value formed from the raw signal of the oscillation acceleration in a freely selectable frequency range. |
| FrequencyBandRmsVelRaw | The RMS value formed from the raw signal of the oscillation velocity in a freely selectable frequency range. |
| FrequencyBandNoiseAccEnvelope | The noise value formed from the raw signal of the oscillation acceleration in a freely selectable frequency range. |
| FrequencyBandNoiseVelEnvelope | The noise value formed from the raw signal of the oscillation acceleration in a freely selectable frequency range. This frequency band is only calculated if the EnableVelocityCalculation bit (configuration in register "SensorConfig" on page 3058) is set for the respective channel; otherwise, 0 is output. |
| FrequencyBandNoiseAccRaw | The noise value formed from the raw signal of the oscillation acceleration in a freely selectable frequency range. |
| FrequencyBandNoiseVelRaw | The noise value formed from the raw signal of the oscillation acceleration in a freely selectable frequency range. This frequency band is only calculated if the EnableVelocityCalculation bit (configuration in register "SensorConfig" on page 3058) is set for the respective channel; otherwise, 0 is output. |

Calculating the total width of the frequency band

The measured damage frequency may vary slightly from the expected frequency. It must therefore be ensured that the frequency band is wide enough to monitor the harmful frequency to compensate for this deviation.

The maximum permissible deviation has been defined as 1/2% of the maximum drive frequency. Since the deviation could occur in either the positive or negative direction, it must be counted twice. This results in the following formula:

$$\text{Total range of frequency band} = 2 * 1/2\% * \text{max. drive frequency [Hz]}$$

Depending on the MaxFrequency selected, a least 3 lines should be configured within each frequency band.

The first lines to the left and right of the configured frequency band are included proportionally based on their distance from the frequency band (see figure in "Frequency bands" on page 3089).

Example

At a maximum drive frequency of 50 Hz, a frequency band should be set at 10 Hz.

10 Hz \pm (0.005 * 50 Hz) = At least 9.75 Hz lower and 10.25 Hz upper frequency band limits

9.26.7.15.13.5 FrequencyBandMax

Name:

FrequencyBandMax01 to FrequencyBandMax32

Maximum value of the respective frequency band in 1/1000 mm/s or g depending on the configuration. See also "Characteristic values (minimum and maximum)" on page 3079 and "Frequency bands" on page 3055 for additional information.

If the frequency band is configured to a velocity signal, this value is only calculated if bit EnableVelocityCalculation (configuration in register "SensorConfig" on page 3058) of the corresponding channel is set; otherwise, 0 is output.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.13.6 FrequencyBandMin

Name:

FrequencyBandMin01 to FrequencyBandMin32

Minimum value of the respective frequency band in 1/1000 mm/s or g depending on the configuration. See also "Characteristic values (minimum and maximum)" on page 3079 and "Frequency bands" on page 3055 for additional information.

If the frequency band is configured to a velocity signal, this value is only calculated if bit EnableVelocityCalculation (configuration in register "SensorConfig" on page 3058) of the corresponding channel is set; otherwise, 0 is output.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.7.15.13.7 FrequencyBandConfig

Name:

FrequencyBand01Config to FrequencyBand32Config

General configuration of individual frequency bands.

Each frequency band can be calculated on any channel with any of the 4 speed data points ("ActSpeed" on page 3056).

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|---|---------|---|
| 0 - 3 | Input channel for calculating the frequency band | 0 | Channel 1 (bus controller default setting) |
| | | 1 | Channel 2 |
| | | 2 | Channel 3 |
| | | 3 | Channel 4 |
| | | 4 to 15 | Invalid |
| 4 - 5 | Signal for calculating the frequency band | 0 | Raw signal speed ¹⁾ (bus controller default setting) |
| | | 1 | Enveloped velocity signal ¹⁾ |
| | | 2 | Raw acceleration signal |
| | | 3 | Enveloped acceleration signal |

1) This is only calculated if the EnableVelocityCalculation bit (configuration in register "SensorConfig" on page 3058) is set for the respective channel; otherwise, 0 is output.

2) Refers to the respective signal (raw signal or envelope signal) on the channel

9.26.7.15.13.8 FrequencyBandConfigRead

Name:

FrequencyBand01ConfigRead to FrequencyBand32ConfigRead

Registers for reading the configuration of individual frequency bands.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.7.15.13.9 FrequencyBandDmgFreq60rpm

Name:

FrequencyBand01DmgFreq60rpm to FrequencyBand32DmgFreq60rpm

Standardized damage frequency at 60 rpm if the frequency band is configured as speed-dependent.

This is multiplied with the configured velocity data point in the module to calculate the frequency band.

The standardized damage frequency must be specified in 1/100.

| Data type | Values | Information |
|-----------|-------------|-----------------------------------|
| UINT | 1 to 65,535 | Bus controller default setting: 0 |

9.26.7.15.13.10 FrequencyBandDmgFreq60rpmRead

Name:

FrequencyBand01DmgFreq60rpmRead to FrequencyBand32DmgFreq60rpmRead

Register to read the standardized damage frequency at 60 rpm for the individual frequency bands.

The standardized damage frequency is specified in 1/100.

| Data type | Values |
|-----------|-------------|
| UINT | 1 to 65,535 |

9.26.7.15.13.11 FrequencyBandTolerance

Name:

FrequencyBand01Tolerance to FrequencyBand32Tolerance

If the frequency band is configured as speed-dependent, then this data point can be used to specify the frequency band's width.

The [FrequencyBandTolerance](#) is subtracted once from the damage frequency calculated from [ActSpeed](#) and [FrequencyBandDmgFreq60rpm](#) to get the frequency band's lower frequency and added once to get its higher frequency.

The tolerance must be specified in 1/100 Hz.

| Data type | Values | Information |
|-----------|-------------|-----------------------------------|
| UINT | 1 to 65,535 | Bus controller default setting: 0 |

9.26.7.15.13.12 FrequencyBandToleranceRead

Name:

FrequencyBand01ToleranceRead to FrequencyBand32ToleranceRead

Registers for reading the tolerance of individual frequency bands.

The tolerance is specified in 1/100 Hz.

| Data type | Values |
|-----------|-------------|
| UINT | 1 to 65,535 |

9.26.7.15.13.13 FrequencyBandLowerFrequency

Name:

FrequencyBand01LowerFrequency to FrequencyBand32LowerFrequency

Minimum frequency for calculating the frequency band if it is not speed-dependent.

The minimum frequency must be specified in 1/4 Hz.

| Data type | Values | Information |
|-----------|-------------|-----------------------------------|
| UINT | 1 to 40,000 | Bus controller default setting: 0 |

9.26.7.15.13.14 FrequencyBandLowerFrequencyRead

Name:

FrequencyBand01LowerFrequencyRead to FrequencyBand32LowerFrequencyRead

Registers for reading the minimum frequency of individual frequency bands.

The minimum frequency is specified in 1/4 Hz.

| Data type | Values |
|-----------|-------------|
| UINT | 1 to 40,000 |

9.26.7.15.13.15 FrequencyBandUpperFrequency

Name:

FrequencyBand01UpperFrequency to FrequencyBand32UpperFrequency

Maximum frequency for calculating the frequency band if it is not speed-dependent.

The maximum frequency must be specified in 1/4 Hz.

| Data type | Values | Information |
|-----------|-------------|-----------------------------------|
| UINT | 1 to 40,000 | Bus controller default setting: 0 |

9.26.7.15.13.16 FrequencyBandUpperFrequencyRead

Name:

FrequencyBand01UpperFrequencyRead to FrequencyBand32UpperFrequencyRead

Registers for reading the maximum frequency of individual frequency bands.

The maximum frequency is specified in 1/4 Hz.

| Data type | Values |
|-----------|-------------|
| UINT | 1 to 40,000 |

9.26.7.15.14 Flatstream

9.26.7.15.14.1 Transferring characteristic values via Flatstream

In function model "Standard", Automation Runtime takes over Flatstream communication for transferring characteristic values. The user is automatically provided with all characteristic values, already properly scaled. As a result, the registers for the characteristic value Flatstream are not shown in the I/O mapping in [Function model 0 - Standard](#).

When using Flatstream in [Function model 0 - Standard](#) and [Function model 1 - Fast master](#), the following should be noted:

- The maximum bus cycle time should not exceed 10 ms.
- The task cycle should either be the same speed and synchronous to the module's bus or faster.

Bus cycle time

Since the characteristic values are transferred over the Flatstream, a maximum bus cycle time of 10 ms should not be exceeded. Otherwise, the data calculated by the module every 300 ms cannot be fully transferred on the bus. If the current transfer is not completed when new characteristic values become available, then they will be discarded. A cycle time of ≤ 10 ms is therefore required in order to ensure seamless measurements.

Task cycle time

It is important to note that the module normally changes the values in the Flatstream in every X2X Link cycle. To optimize performance and avoid missing any values in the task, it is important to select a task cycle that is either the same speed and synchronous to the module's bus or faster. This also applies to fieldbus connections between the CPU and bus controller. If this is not possible for some reason, it is also possible to change the ForwardDelay of the Flatstream (see ["The Forward function on the X20CM4810" on page 3099](#)).

Registers for the characteristic value Flatstream

The following registers are needed to transfer characteristic values:

["ParameterInputSequence01" on page 3808](#)

["ParameterRxByte01-13" on page 3806](#)

["ParameterOutputSequence01" on page 3807](#)

This results in an [InputMTU](#) of 13 and an [OutputMTU](#) of 0 bytes for the characteristic value Flatstream.

Structure of the characteristic value Flatstream

Each characteristic value transferred from the module via Flatstream has a length of 3 bytes with the high byte first. For the exact format, see ["Characteristic values" on page 3070](#). The stream has a total length of 240 bytes. First, all characteristic values from channel 1 are transferred, then those from channels 2, 3 and 4. The 32 frequency bands then follow next.

The RmsVelRaw and RmsVelEnvelope characteristic values and FrequencyBandxx are only transferred if they are set to a velocity signal and the EnableVelocityCalculation bit for the respective channel is set. Otherwise, 0 is output. EnableVelocityCalculation is configured in the ["SensorConfig" on page 3058](#) register.

| Byte offset in the stream | | | | Characteristic value |
|---------------------------|-----------|-----------|-----------|-----------------------------------|
| Channel 1 | Channel 2 | Channel 3 | Channel 4 | |
| Channel parameters | | | | |
| 0 | 36 | 72 | 108 | RmsAccRaw |
| 3 | 39 | 75 | 111 | RmsVelRaw |
| 6 | 42 | 78 | 114 | RmsAccEnvelope |
| 9 | 45 | 81 | 117 | RmsVelEnvelope |
| 12 | 48 | 84 | 120 | PeakHighFrequency |
| 15 | 51 | 87 | 123 | RmsHighFrequency |
| 18 | 54 | 90 | 126 | Iso10816 |
| 21 | 57 | 93 | 129 | CrestFactorRaw |
| 24 | 60 | 96 | 132 | KurtosisRaw |
| 27 | 63 | 99 | 135 | PeakRaw |
| 30 | 66 | 102 | 138 | SkewnessRaw |
| 33 | 69 | 105 | 141 | RmsRaw |
| Frequency band 1 - 32 | | | | |
| 144 | | | | FrequencyBand01 |
| : | | | | : |
| 237 | | | | FrequencyBand32 |

9.26.7.15.14.2 Uploading buffers via Flatstream

For information about Flatstream, see ["Flatstream communication"](#) on page 3802.

Uploading buffers via Flatstream is available on the module in [Function model 0 - Standard](#) and [Function model 1 - Fast master](#).

Library **AsIOVib** is available for uploading the buffers from the module. For a description of the library, see ["Automation Help - Programming - Libraries - Direct I/O access - AsIOVib"](#).

The raw data buffers (raw signal and FFT) from the module are transferred on request (buffer Flatstream in the Tx direction) from the module via the buffer Flatstream (Rx direction) but only if the buffers were previously frozen on the module with settings `RequestBufferLock01 = 1` and `BufferLockValid01 = 1`. It is important to note that the module refreshes the data points of the buffer Flatstream every X2X Link cycle. Once the transmission is complete, the buffer from the stream needs to be "reassembled" on the PLC.

Registers for the buffer Flatstream

The following registers are needed to upload buffers:

["BufferInputSequence01"](#) on page 3808

["BufferRxByte01-05"](#) on page 3806

["BufferOutputSequence01"](#) on page 3807

["BufferTxByte01-04"](#) on page 3806

This results in an `InputMTU` of 5 and an `OutputMTU` of 4 bytes for the buffer Flatstream.

Buffer upload procedure

Before a buffer can be uploaded from the module, the buffers on the module must first be locked by setting `RequestBufferLock01 = 1`. The upload can only begin once the buffers have been locked by setting `BufferLockValid01 = 1`.

If a velocity buffer is uploaded, it only contains values if bit `EnableVelocityCalculation` of the corresponding channel is set; otherwise, 0 is output. Bit `EnableVelocityCalculation` can be configured in register ["SensorConfig"](#) on page 3058.

A buffer first needs to be requested from the module via the buffer Flatstream (Tx direction). Meaning:

- `BufferTxByte01`: Value 0x83 (frame end and 3 bytes are valid)
- `BufferTxByte02`: The requested buffer from the module
- `BufferTxByte03`: High byte of the number of the values to be read (per 4-byte value)
- `BufferTxByte04`: Low byte of the number of the values to be read (per 4-byte value)

The sequence is subsequently increased by 1. As soon as the sequence has been confirmed by the module, it is important to set the number of valid bytes in `BufferTxByte` to 0; otherwise, the module interprets this as a new request. The module can temporarily store up to 2 consecutive requests.

As soon as the module receives the request, it begins streaming the requested number of values from the specified buffer via the buffer Flatstream (Rx direction). Values are always transferred in 16.16 fixed data point format (1/65536) with the high byte first. A scaling factor is transferred first. All other values are then multiplied by this factor. With time signal buffers, the first value according to the scaling factor is always the oldest. With FFT buffers, the first value according to the scaling factor is always 0 Hz. FFT buffers are only valid from the configured `MinFrequency` to the configured `MaxFrequency` of the respective signal (raw or envelope) and the respective channel.

For the time and frequency intervals of individual values, see register ["MinFrequencyRaw"](#) on page 3088 or ["MinFrequencyEnvelope"](#) on page 3087.

`RequestBufferLock01` must be set to 1 throughout the entire uploading process. Once the requested buffers have been uploaded from the module, the lock can be reset. In the module, the buffers are then once again filled with new values. After some time has passed, they can be locked and uploaded again (see register ["Control"](#) on page 3057).

| Buffer number (dec.) | | | | Buffer | Maximum number of values (1 values = 4 bytes) |
|----------------------|--------------|--------------|--------------|--|--|
| Channel 1 | Channel 2 | Channel 3 | Channel 4 | | |
| 9 | 11 | 13 | 15 | Raw signal (filter value: "MaxFrequencyRaw" on page 3086) | 8193 or 65535 ¹⁾ |
| 25 | 27 | 29 | 31 | Envelope signal (filter value: "MinFrequencyEnvelope" on page 3087) | 8193 or 65535 ¹⁾ |
| 66 | 70 | 74 | 78 | FFT amplitude spectrum raw velocity signal (filter value: "MaxFrequencyRaw" on page 3086) | 4097 ¹⁾ |
| 67 | 71 | 75 | 79 | FFT amplitude spectrum raw acceleration signal (filter value: "MaxFrequencyRaw" on page 3086) | 4097 ¹⁾ |
| 82 | 86 | 90 | 94 | FFT amplitude spectrum envelope signal velocity (filter value: "MinFrequencyEnvelope" on page 3087) | 4097 ¹⁾ |
| 83 | 87 | 91 | 95 | FFT amplitude spectrum envelope signal acceleration (filter value: "MinFrequencyEnvelope" on page 3087) | 4097 ¹⁾ |

1) The first value in the buffer is the scaling factor.

In special applications it may be necessary to upload larger buffers.

In register "[SensorConfig](#)" on page 3058, a buffer length of 8193 or 65535 values can be configured using bit 14. This makes it possible to read the raw signal and envelope signal (buffer number 9, 11, 13, 15, 25, 27, 29 and 31) using 65535 values, including the scaling factor, from the module. However, the FFT buffers still contain 4097 values including scaling factor and refer to the last 8193 values of the 65535 values of the raw or envelope signal.

After locking the buffer for the upload (RequestBufferLock01) until the next locking, it is necessary to wait until the longest buffer is filled again. If the buffer tries to lock again before this time elapses, it is prevented by the module until after the buffer is filled.

9.26.7.15.14.3 The Forward function on the X20CM4810

The ForwardDelay for the buffer Flatstream can be configured acyclically in [Function model 0 - Standard](#) and [Function model 1 - Fast master](#) in the I/O configuration of the module (BufferForwardDelay01). When using the "Fast master" function model, the ForwardDelay can also be configured acyclically for the parameter Flatstream in the I/O configuration (ParameterForwardDelay01).

Forwarding for the parameter and buffer Flatstreams can be adjusted acyclically (see registers "[ParameterForward01](#)" on page 3826 and "[BufferForward01](#)" on page 3826). However, it should only be adjusted after the forward delay for the respective Flatstream has already been set.

When using an SG4 CPU, the ForwardDelay cannot be configured manually for the parameter Flatstream. Starting with J3.09 and J4.01 of Automation Runtime, it is automatically configured and in earlier versions, it is ForwardDelay 0.

9.26.7.15.14.4 Flatstream communication

For a description of Flatstream communication, see "[Flatstream communication](#)" on page 3802

9.26.7.15.15 Using the module with on the fieldbus

9.26.7.15.15.1 Bus controller with FieldbusDESIGNER support

Only [Function model 1 - Fast master](#) and [Function model 2 - Slow master](#) are available for this.

The module is configured using FieldbusDESIGNER in Automation Studio. Implementation must be handled on the master.

9.26.7.15.15.2 Bus controller without FieldbusDESIGNER support

Only [Function model 2 - Slow master](#) is available for this. Configuration and implementation must be handled on the master.

9.26.7.15.15.3 B&R SG4 CPU with an interface module

This combination offers the following advantages:

- Modular condition monitoring solution possible
- All characteristic values prepared by Automation Runtime (no extra work required for implementation)
- Communication with the master via the interface card

9.26.7.15.15.4 CANIO bus controller

Only [Function model 254 - Bus controller](#) is available for this. Configuration and implementation must be handled on the master.

9.26.7.15.16 Assignment of the task class

Name:

Cycle time

By assigning the cycle time to a task class, the data exchange between the CPU and module can be prioritized and adapted to the requirements of the application. Faster task classes result in increased data throughput, but this increases the system load.

Information:

Using a task class that is too slow can result in new data from the module not being available within a measurement cycle.

The task class must be less than or equal to to the [maximum cycle time](#).

Information:

This configuration involves a driver setting that cannot be changed during runtime!

| Data type | Values | Information |
|-----------|--------|-----------------|
| - | 1 to 8 | Task class used |

9.26.7.15.17 Maximum cycle time

The maximum cycle time defines how far the cycle time of the X2X Link can be increased without causing a communication error or impaired functionality.

| Maximum cycle time | |
|---|-------|
| Function model 0 - Standard Function model 1 - Fast master | 10 ms |
| Function model 2 - Slow master Function model 254 - Bus controller | - |

9.26.7.15.18 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|---------------------|--------|
| All function models | 400 µs |

9.26.7.16 Condition monitoring / Oscillation analyses

9.26.7.16.1 Basic information

System availability is one of the most important criteria in machine operation. For this reason, increasing and ensuring this availability over the long term is a primary objective of the system operator.

Unplanned stoppages and the resulting loss of production can lead to substantial costs. The implementation of condition monitoring has proven to be a very good method for supporting anticipatory maintenance.

9.26.7.16.1.1 What is condition monitoring?

Condition monitoring involves recording the status of the machines at regular intervals by measuring important values in order to recognize impending problems in the system. The goal is to recognize imminent damage early enough so that a faulty machine part can be repaired or replaced before it leads to consequential damage or a partial or complete breakdown of the system.

The specific purpose of condition monitoring is to collect and process sensor data (e.g. oscillations, temperatures, lubricant conditions, pressures, flows) that can be used to assess the overall condition of the system.

Deviations from normal process or system conditions are caused by defects, which can occur for a variety of reasons. If corresponding countermeasures are not taken, this can quickly lead to a malfunction and breakdown of the system. Monitoring the sources of defects through the analysis of machine parameters can make it possible to recognize malfunctions as early as possible in order to take preventive action. Possible responses can include, for example, an error message or warning to the operator or an automated action for fault clearance and prevention of damage all the way up to automatic shutdown.

The integration and systematic implementation of condition monitoring provides many advantages:

- System components are only repaired or replaced when actually necessary. Potential defects are recognized early on in operation.
- Reliability can be significantly increased by integrating condition monitoring into the process.

Bathtub / Deterioration curve

The operating performance of every mechanical component changes over the course of operation, with each component becoming defective at some point. It is crucial to recognize such a change before the component can no longer fulfill its function. This behavior can be illustrated very well by the so-called "bathtub curve". This indicates the probable failure rate over time.

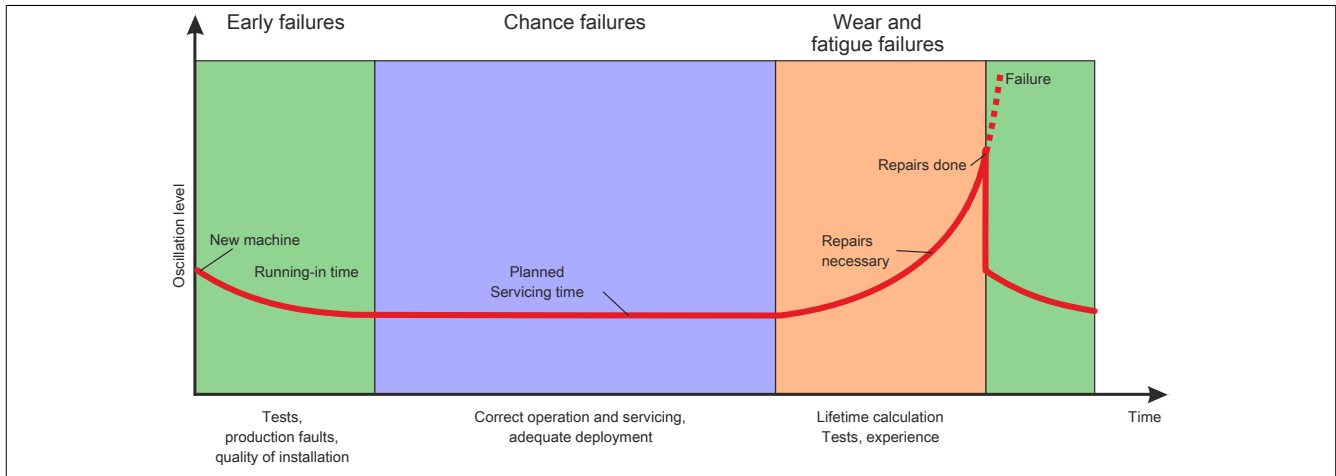

Figure 205: Bathtub curve illustrating the 3 typical phases

Each component is subject to the regularities of this curve, with a typical trend emerging as a result.

- **Area 1 (early failures)** is characterized by a decreasing failure rate. Early failures are caused almost exclusively by errors in assembly or construction. However, special care and quality during production and commissioning significantly reduces the failure rate at the beginning. This area also explains the increased failure performance after an intervention in a system that functions well.
- During continuous operation in **Area 2 (chance failures)**, the failure rate is almost consistent. These chance failures are fundamentally difficult to ascertain and, most importantly, not easily influenced. Operating and maintenance errors contribute towards an increase in the failure rate in this region.
- The failure rate increases dramatically in **Area 3 (wear and failure due to fatigue)**. Wear and fatigue failures are primarily characterized by damage that progresses slowly over time.

The trend provides valuable information about the failure probability of the parameters measured by condition monitoring. This usually behaves like the bathtub curve, i.e. an increase in the characteristic value signifies a change in the system. The characteristic values can be synchronized with the operating parameters through the integration of automation technology. Assessing curve performance and incorporating operating parameters makes it possible to identify the best time to perform service work depending on condition.

In addition, oscillations are often representative of the condition of a machine or component. They are a good indication of wear or damage. One example of this is roller bearings. Surface damage (pitting) leads to increased oscillations in the bearing housing. These can be measured and evaluated. An increase in oscillations during operation indicates damage and/or increased wear. By constantly observing this condition, deviations from normal operation can be recognized immediately.

Damage development and the damage chain

Explaining damage development with a roller bearing example

The majority of bearing damage develops slowly and usually without being noticed. In many cases, it is only once the damage is more advanced that irregular running and unusual operating noises indicate bearing damage. This points to material fatigue, e.g. chipping or altered radial clearance through wear.

If the damage is so advanced that it can be detected without measuring equipment, spontaneous failures such as blockages and breakage of the bearing housing components often occur.

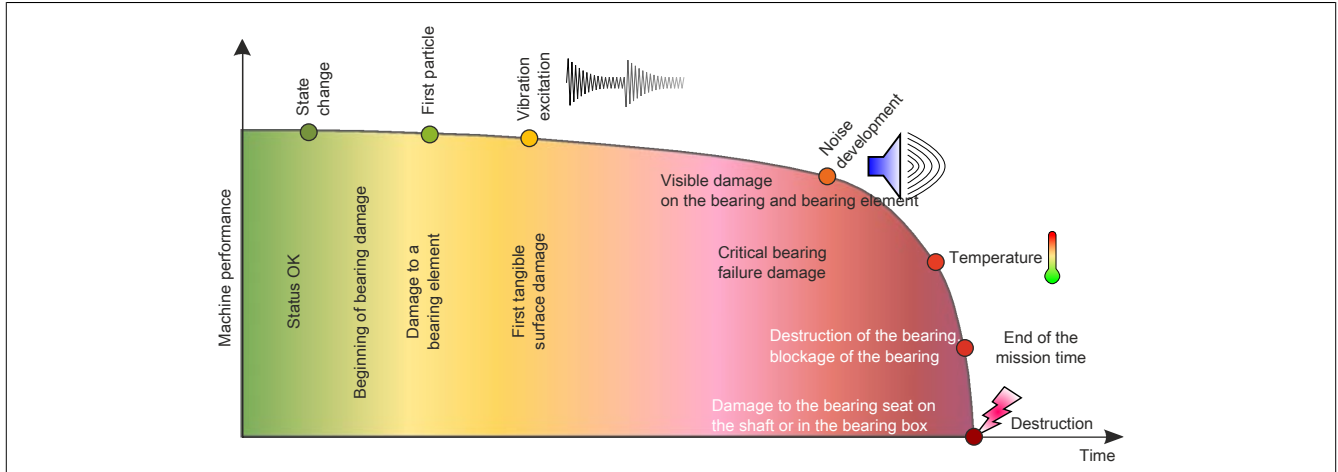

Figure 206: Illustration of the damage chain and the development of damage over time

The damage chain illustrated in the image above presents condition monitoring as an important tool in the condition-based operation and maintenance of a system.

It is possible to draw conclusions about the condition of the machine or its components from the parameters recorded by the sensors. Deterioration of the condition of components or system parts becomes apparent through the detection and observation of their condition, the consideration of the trend and, if necessary, through the detailed analysis of the measurement data obtained. Based on this, targeted measures can be put in place for maintenance.

Condition monitoring is a suitable option under the following conditions:

- Measurable parameters that correlate with a failure need to be identified and selected.
- The failure cannot be prevented by redesign or altered usage.
- Events lead to failures that occur randomly.
- Sufficient warning time must be given in advance before a function fails.

The consideration of condition monitoring resources is not permitted to be limited to the consideration of the recording of operating conditions alone but should be integrated into this as part of a general asset management strategy. In order to manage this, all types of condition monitoring and industrial diagnostics should be combined into an overall strategy.

For a failure-oriented operational mode ("reactive maintenance"), components are only replaced if they can no longer fulfill their function. For planned operation ("preventive maintenance"), components are replaced at a certain point in time – regardless of their current condition.

For condition-based maintenance, the area where maintenance is planned can be significantly isolated while reducing the risk of failure at the same time.

| | Advantages | Disadvantages |
|-----------------------------|---|---|
| Reactive maintenance | <ul style="list-style-type: none"> - Utilization of the wear reserve - No costs during the period of use | <ul style="list-style-type: none"> - Unexpected failure - Consequential damage - High downtime costs - Low operational safety |
| Preventive maintenance | <ul style="list-style-type: none"> - Can be planned well | <ul style="list-style-type: none"> - No utilization of the wear reserve - Increased risk of failure after maintenance - Repair costs |
| Condition-based maintenance | <ul style="list-style-type: none"> - Early recognition of problems - Downtime can be planned - Utilization of the wear reserve - High operational safety - Avoidance of consequential damage | <ul style="list-style-type: none"> - Dealing with the issue - Investment costs - Additional costs for equipment to measure condition |

9.26.7.16.1.2 Conventional condition monitoring

- There exists a lot of measurement and process data that is not used for condition monitoring (CM). Links and correlations with process parameters and further CM parameters can often be made possible only with considerable expenditure.
- CM systems are implemented as "isolated applications". In such cases condition monitoring is performed by standalone sensor and measurement systems with standalone hardware and software
- The range of different systems can lead to significant problems in the on-site operation of the system. Different software solutions make it more difficult since there is separate hardware and a separate user interface for each CM method and each CM tool.
- In many cases, necessary expert knowledge specific to a system is not available. The complexity of some configuration tools exceeds the user's existing expertise.

Using the X20CM4810 together with B&R standard modules has the following advantages:

- Easy exchange of process data and condition monitoring data
- Easy integration of parameters in the overall process
- Modular construction

9.26.7.16.1.3 Overview of condition monitoring methods

| Method | Brief description of operation | Available signals/interfaces |
|--|--|--|
| Determination of the condition of coolants and lubricants, visual assessment, filtering, ferrography, magnetic detection, spectroscopy, radioactive trace analysis | Quantitative examination of wear products (filtering, magnetic catches, ferrography, spectral oil analysis, particle counting) that are obtained from the lubricant oil or coolant fluid Regular taking of samples according to a defined time schedule or according to operating hours Quantitative comparison of the samples | Using suitable measurement systems, these condition monitoring methods can be processed in the B&R system using analog/digital inputs or bus controller modules. |
| Thermal diagnostics Temperature sensors, thermometry, infrared measurement technology | Recording of temperatures through sensors with different physical modes of action Recording of temperature distribution through detection of infrared radiation | |
| Acoustic emission analysis Airborne sound measurement, pulse analysis, pulse density fluctuation analysis, sound pressure measurement, sound emission location | Airborne sound measurement from infrasound to ultrasound using a microphone Multidimensional microphone structure for emission source location Recognition of microdamage (cracks), etc. through the measurement of acoustic emissions of transient waves with high frequencies | |
| Vibration measurement Structure-borne sound measurement, FFT analyses, order analyses, modal analyses | Vibroacoustic diagnostics Measurement of the structure-borne sound at bearing positions or structures with accelerometers, analysis and evaluation | |
| Electrical parameters, motor current analysis, Isolation resistance measurement | Compilation of electro-technical parameters and analysis with regard to condition monitoring | |

9.26.7.16.2 Oscillation measurement technology

9.26.7.16.2.1 Sensor technology

Oscillation sensors convert the mechanical oscillations of the machines being monitored into electrical signals.

For the most part, structure-borne sound, i.e. the sound that spreads through a solid object, is measured.

The acceleration measured within the scope of the condition monitoring is typically measured with piezoelectric sensors. The oscillation sensors being used utilize the piezoelectric properties of quartz or certain ceramics. The actual measured value is a force that is proportional to the acceleration.

The piezoelectric effect involves a charge separation when a force acts on the piezoelectric material. This is in proportion to the force and is consequently proportional to the acceleration. Piezoelectric quartz or piezoelectric ceramic is used as the piezoelectric material. The output signal is an electrical charge that is specified in pC (picocoulombs). A charging amplifier is necessary in order to convert the charge into a voltage signal.

The Integrated Electronics Piezo Electric (IEPE) technology used in B&R sensors strengthens the signal directly in the sensor and emits it as a low-resistance voltage signal. Sensor sensitivity is specified in mV/g.

1 g = 9.81 m/s² (gravitational acceleration)

Information:

Piezoelectric sensors cannot measure static magnitudes.

Basic design

In a compression sensor, the piezoelectric crystal is held between a seismic mass and the base of the sensor. Through the acceleration that occurs, the force acting upon the crystal increases or decreases. The larger the seismic mass, the larger the output signal.

Sensors of this design can be built with a very high stiffness and thus have a correspondingly high resonance frequency.

Influencing variables on the sensor

Mounting direction - Preferred direction

Oscillation sensors can be fitted at any location. The installation position usually results from the measuring task itself. Nevertheless, vibration sensors have a preferred measuring direction. This is normally marked on the sensor housing.

Oscillations perpendicular to the installation position also act upon the sensor. These can be compensated as much as possible through appropriate constructive measures and suitable selection of the piezoelectric crystal.

Installation position

B&R vibration sensor 0ACS100A.00-1 is designed for measurements in the longitudinal axis; sensor 0ACS100A.90-1 is designed for measurements in the transverse axis.

Cross-sensitivity

Oscillations in all directions act upon the sensor. The sensor preferentially transmits vibrations in its main direction, i.e. in the direction indicated on the sensor. Vibrations deviating from this main direction, however, are also registered by the sensor and transmitted differently in the overall signal depending on the design.

Cables

When transferring a signal over a connector, errors such as noise, ground loops and contortions may occur. This influence is particularly important in the transfer of charges since system noise is a function of the cable's capacity. When using IEPE technology, the sensor produces a high voltage signal with a low source impedance due to its internal electronics.

As a result, this technology is well suited for signal transmission over long lines.

The power supply unit provides constant current to supply the IEPE electronics in the sensor. The maximum frequency that can be transferred via the test lead without considerable loss depends on the length of the cable, the cable capacity and the ratio between the output amplitude and the constant current.

Information:

Maximum cable length when using B&R cable 0ACCxx0.01-1: 100 m

Temperature influence

All piezoelectric materials also have a distinct pyroelectric effect. This describes the change in the electric polarization of ferroelectric materials as a result of a change in temperature. This effect is undesirable since it often leads to charge separations in the oscillation measurement. These arise from the change in temperature and not through the mechanical vibrations occurring in the measured object.

However, this effect can be limited due to the design. The interferences are grouped together in the interference transfer factor for temperature changes.

Temperature drift

The values specified in the sensor's technical data have been determined as a step response to a change in temperature for the lower electrical limit frequency $f_u = 1$ Hz.

Changes in temperature, in particular, cause interference in the low frequency domain below $f = 10$ Hz since this is generally a low frequency event.

Interference

In the vicinity of electromechanical machines such as motors and generators, electromagnetic alternating fields and the associated induction and magnetostriction cause a reaction on the sensor. Due to the shielding concept used and the use of IEPE technology, however, this retroactive effect is very low.

This effect is specified in the interference transfer factor. It is determined by a magnetic flow density of 0.01 T and a frequency of 50 Hz.

Information:

B&R sensors have an isolated base. When using sensors from other manufacturers, it is important to pay attention to isolation/screening in order to minimize interference. This allows interference frequencies with single and double mains frequency.

Linearity

The piezoelectric sensor is linear over long distances of the frequency response.

Frequency response

The frequency response of the sensor is determined by its mechanical construction. The seismic mass and the rigidity of the inner structure is crucial here, as is its construction.

The sensitivity is linear in other areas of the frequency response. The frequency response only increases significantly when near the resonant frequency. Since misinterpretations can occur in proximity to the resonant frequency, the resonant frequency must be correspondingly high.

Figure 207: Frequency response of B&R sensors 0ACS100A.00-1 and 0ACS100A.90-1

Installing sensors

Sensors can be connected to object to be measured using various methods. How the sensors are installed on the measurement object is crucial for the quality of the overall measurement.

In order to transfer all frequency portions to be measured to the sensor accordingly, very good coupling of the sensor to the mechanical component is necessary.

Machine parts may be subject to temperature-related expansion and deformation, with the result that the sensor no longer has its whole measurement surface available. This affects the quality of the measurement.

Figure 208: Temperature deformation of a machine part (excessive deformation shown)

Information:

For optimal measurement, the mounting surface of the sensor must be flat and the sensor must be fully supported.

In order to increase the quality of the measurement accordingly, a fixed connection to the measurement object is necessary. Cover plates and plastic parts are therefore not suitable for securing sensors.

The following methods are available for installing sensors:

Figure 209: Overview of installation methods

Of all of the mounting methods, fastening by means of a screw is preferable due to the low attenuation between the sensor and the measurement surface.

Typical sensor installation is performed by screwing the sensor to the measurement object with what is called a stud (supplied with the sensor). Studs are specially-made setscrews made from special materials that facilitate the optimal transfer of vibrations.

If the mounting location is well prepared and the sensor is screwed on correctly, frequencies of up to approximately 10 kHz can be transferred without significant loss.

Information:

To ensure measurements of sufficient quality, B&R recommends mounting the sensor with a screw.

Ground loops can occur when the module and sensor are mounted far apart. If necessary, isolated mounting must be performed using an isolated adhesive mounting plate.

The resonant frequency is reduced by additional elements such as an isolation flange, collar screw, magnetic clamp and probe tip positioned between the coupling surfaces. The coupling becomes softer using these elements. These differences can be clearly seen in the frequency response diagram

Different frequency responses of the relative voltage transfer factor are illustrated in the image below.

Figure 210: Attenuation of the different types of sensor mounting

The choice of mounting is influenced by the resonance frequency and temperature. The following table shows how strongly these influences impact on the different mounting methods.

| | Resonant frequency | Temperature |
|----------------------------|--------------------|-------------|
| Stud | ● | ● |
| Instant adhesive | ● | ● |
| Beeswax | ◐ | ○ |
| Double-sided adhesive tape | ○ | ◐ |
| Magnetic clamp | ◐ | ● |
| Probe tip | ○ | ○ |

Effects on the installation methods:

Installation procedure

Depending on the conditions of the location, sensors can be screwed directly onto the surface of the object to be measured.

STEP 1: As smooth and flat a surface as possible is needed to mount the sensors. The required size depends on the sensor; see the data sheet.

For a vertical installation position:

See ["Dimensions" on page 3167](#).

For a horizontal installation position:

See ["Dimensions" on page 3170](#).

STEP 2: An M8 blind hole is needed to attach the B&R sensors.

STEP 3: To further improve the transfer performance, a thin layer of silicon grease can be applied between the object surface and the sensor mounting surface. This is not necessary in most cases and is only useful when measuring particularly high-frequency vibrations.

STEP 4: The sensor should be tightened by approx. 8 Nm when using the M8x1 screw thread. If necessary, the sensor can additionally be secured with adhesive.

Sensor positioning

In order to optimally measure and detect the sound propagation of damage, the position of the sensor must be carefully selected. Although it is often not possible to mount a sensor at the absolute best position, this is not always necessary. Since sound waves propagate throughout the entire structure, the damage frequencies can be measured at various locations with varying intensity or amplitude (green arrow). If a flexible connection is used, a valid measurement is no longer possible (red arrow).

Figure 211: Suitable and unsuitable sensor attachments

9.26.7.16.2.2 Oscillations - Overview of measuring structure-borne sound

Oscillations

Oscillations are forms of movement that occur very frequently in nature. Harmonic oscillation is the third basic type of form of movement alongside uniform movement and uniform accelerating movement. An oscillation or vibration is a cyclic, i.e. repetitive simultaneous movement of a structure in its rest or equilibrium position.

Figure 212: Illustration of a basic oscillation

If a fixed medium is stimulated by an impact, structure-borne sound spreads throughout it. This consists of additional frequencies which are determined by the shape of the structure and the material it is made from (e.g. gong or concrete block).

A portion of the structure-borne sound energy is converted into airborne sound through the surrounding atmosphere.

Figure 213: Propagation of structure-borne sound

The measurement and subsequent analysis of the mechanical oscillations on stationary and rotating parts of machines, support structures and pipelines has become accepted as technically possible with practically applicable monitoring procedures.

The absolute bearing oscillation is measured on the housing of the machine and involves the movements of the housing in relation to a fixed reference point in the room.

Mechanical oscillations are a good parameter for detecting initial defects and damage and can be used for machine diagnostics.

There are numerous overlapping causes for oscillations. The size (amplitude) of the oscillation depends on several factors such as attenuation through joints or grease, the rigidity of the component, the housing and foundations and much more.

Damage is always a consequence of stress. If cyclic stress occur, it can be identified by its excitation frequency and intensity.

Resonant frequency

Every machine has what are known as resonant frequencies. These must be observed during operation since with these frequencies the amplitude of the oscillation increases dramatically, putting strain on the mechanical components. If harmonic oscillations occur for a long time in proximity to the resonant frequency, this can lead to a so-called "resonance catastrophe", which causes the destruction of the affected part.

Figure 214: Increase of the amplitude in proximity to the resonant frequency

Causes of oscillations:**Imbalance**

Per DIN ISO¹⁾, an imbalance is present in a rotating system if forces or oscillation movements are transferred to the bearing as a consequence of imbalanced centrifuges.

Imbalances on a rotating structure not only cause forces on the bearing and foundations, but also oscillations in the machine. These oscillations have a harmonic nature, with the excitation frequency corresponding to the rotary frequency of the imbalanced rotor.

Alignment errors

The main function of coupling is to connect 2 shafts in order to achieve a statically determinate complete system. In addition to transferring torque, couplings also offset misalignment (radial, axial, angular) to a certain extent. However, if the misalignment exceeds the compensation capability of the coupling, additional loads such as increased bearing forces, forced shaft deformation and axial forces occur for the machine elements involved.

Oscillations have a harmonic nature and are bound to the rotary frequency of the misaligned shafts and the multiples of this frequency. Misalignment can be measured using the rotary frequency of the misaligned part or its harmonic oscillations.

Impacts

Foreign objects as well as loose or colliding parts can cause shocks between rotating and stationary parts. These shocks repeat periodically once or several times each time the shaft revolves.

The frequency of these shock repetitions corresponds to the rotary frequency of the shaft or its harmonic frequency.

Roller bearing damage

Most bearing damage results from changes on the surface (pitting). By rolling over the damaged area on the inner ring, outer ring, cage or rolling element, pulse-shaped shocks occur that make the bearing structure and its components vibrate.

Each of these shocks appears in the oscillation signal through the typical course of a shock sequence. Characteristic values can be obtained from these measurements that give an indication of the condition of the bearing.

The excitation frequency on the inner ring, outer ring, cage and roller bearing damage is specified by the bearing manufacturer.

Magnetic induction

A rotating magnetic field causes counterforces in the stator of the machine. This electric magnetic stimulation often causes oscillations on the electric motors that are hard to detect.

Inverters also often lead to an inference of oscillations, the cause of which is of an electrical magnetic nature.

Effects

Machines and systems with moving parts cause mechanical oscillations. The effects on the immediate location and surrounding area include tremors and structure-borne sound, often creating a disturbing noise development.

Increased vibrations can lead to malfunctions in the machine, particularly in measurement and control devices. If this causes the measuring equipment to resonate as well, incorrect measurements will result and manufacturing quality will suffer.

In addition, stress will develop on the components of the machine. Unwanted vibrations lead to increased wear with partly plastic distortion of components and increased crack formation all the way up to failure.

Noticeable oscillations are felt through the equilibrium organ and sense of touch. Long-term exposure can impair working performance and well-being, even leading to health damage.

¹⁾ 1925 DIN ISO 1925: Issue: 1996-11 Mechanical oscillations - Balancing technology - Terms (ISO 1925:1990 + AMD 1:1995)

Oscillation parameters

| Parameter | Explanation | Symbol | Formula |
|------------------|---|----------|--------------------------------|
| Rest position | The structure's undisplaced position | s_0 | |
| Amplitude | The greatest displacement from the rest position | A | |
| Period duration | Minimal time span for a complete oscillation after which a structure has reached its initial position and initial speed again | T | |
| Frequency | Number of oscillations per unit of time | f | $f = 1 / T$ |
| Angular velocity | Change of angle in the radian measure over time | ω | $\omega = 2 \cdot \pi \cdot f$ |

Large mechanical oscillations

The amplitude of an oscillation can be defined by its path (s), velocity (v) and acceleration (a) values.

These 3 values have a consistent relationship with one another and can be converted from one to the other using simple calculations.

The B&R sensors measure oscillation acceleration. The unit is m/s^2 . The acceleration is also often specified with the unit g ($1 g = 9.81 m/s^2$) for the acceleration due to gravity.

For some diagnoses, however, the oscillation velocity or oscillation path is more meaningful. The acceleration can then be passed converted to the oscillation velocity through integration. The path can be calculated from the acceleration by using integration twice.

Mathematical relationship

Displacement

$$s = \hat{s} \cdot \sin(\omega t + \varphi)$$

Oscillation velocity

$$v = \frac{ds}{dt} = \hat{s} \cdot \omega \cdot \cos(\omega t + \varphi)$$

Oscillation acceleration

$$a = \frac{d^2s}{dt^2} = \frac{dv}{dt} = -\hat{s} \cdot \omega^2 \cdot \sin(\omega t + \varphi)$$

Information:

Displacement is not calculated by the module.

Figure 215: The s-v-a relationship

A harmonic oscillation can be clearly described by its amplitude, frequency and phase angle.

- The amplitude in the path, velocity or acceleration indicates the instantaneous value.
- The frequency describes how often an oscillation changes within one second. In oscillation diagnostics, this plays an important role since many frequencies can be assigned to one cause.
- The phase angle refers to the starting point of the oscillation. This is usually not that important since in most cases several oscillations are present.

Fast Fourier transforms (FFT)

Oscillation signals generally consist of a number of oscillations that occur simultaneously and overlap. Individual frequencies are not directly evident from a timing diagram.

Figure 216: Timing diagram of an oscillation

Calculating a line spectrum is suitable for analyzing a mixture of oscillations of different frequencies where each participating oscillation and their frequencies and amplitudes are represented by a single line.

Within the scope of condition monitoring, spectra are a valuable aid in finding the cause of a failure. Many frequencies can be traced back to individual components so that damaged components can be identified.

Adding sinusoidal oscillations to generate a signal

The following figures show how a square wave signal is created by overlapping sinusoidal oscillations.

Sinusoidal oscillation with 1 Hz and an amplitude of 1.

Figure 217: Pure sinusoidal oscillation

Sinusoidal oscillation with 1 Hz and an amplitude of 1 and sinusoidal oscillation with 3x the base frequency, i.e. 3 Hz and a lower amplitude.

Figure 218: Sinusoidal oscillation with one harmonic

Sinusoidal oscillation with 1 Hz and an amplitude of 1 and sinusoidal oscillations with 3x, 5x, 7x and 9x the base frequency and a lower amplitude.

Figure 219: Sinusoidal oscillation with several harmonics

General description

The Fourier transform is the basic principle of frequency analysis. It assumes that each harmonic oscillation can be broken down into any number of sinusoidal and cosinusoidal waves, the sum of which reproduces the original oscillation. Linked individual waves are "broken down" again accordingly.

Probably the most well-known concept in connection with signal processing and frequency analysis is the fast Fourier transform, or FFT.

In order to be able to evaluate single partial oscillations into amplitude and frequency, the digitized time signal is converted into a frequency spectrum. In addition, a small extract is taken from the signal; this is known as the time window. Using the FFT algorithm, the frequency spectrum is calculated from this so that each involved oscillation and its associated frequencies and amplitudes is shown as a single line in the line spectrum.

Example

For a single sine signal with a constant frequency, a single line is shown in the frequency spectrum.

Information about using FFT

Window functions

Depending on the signal structure and boundary conditions, discontinuities may occur at the time window limits of the extract taken. These reflect partial oscillations that do not exist at all in reality.

These discontinuities arise if the period of the sampling does not correspond to an integral multiple of the period of the time signal. This occurs with practically every measured signal since this is composed of a number of signals with different period durations.

Window functions are used to suppress these discontinuities. This is done by multiplying the input signal with the window function and supplying the Fourier transform with the resulting signal.

Common window functions are:

- Triangular window
- Hann window
- Hamming window

All of these functions share the fact that they approach zero at the edges, so the periodic continuation now no longer has any jump discontinuities.

Information:

The Hann window is used in the X20CM4810 module.

Sampling

Scanning or sampling refers to the recording of an analog value at certain intervals.

At defined times, the precise voltage level of the signal is recorded and stored. The distance Δt (Delta t) between the recording points is called the sampling interval.

Figure 220: Sampling of a curve

If the actual sampling rate is many times higher than the theoretically required sampling frequency, it is called "oversampling". The reduction of the sampling rate to the required rate is called "downsampling".

If the Fourier transform is used in accordance with the sampling theorem on a purely sinusoidal signal whose frequency corresponds exactly with a node in the frequency spectrum (whole number multiple of the frequency resolution), then this signal appears as a single line in the spectrum. If the frequency of the sinusoidal oscillation does not fall on a node in the frequency spectrum, then it will appear as 2 neighboring lines whose vertical relationship to each other is indirectly proportional to the frequency deviation of the respective node.

In practice, a pure sinusoidal signal will rarely occur. Rather, a signal will consist of a multitude of sinusoidal oscillations of different frequencies. As a result, the resulting frequency spectrum also consists of a large number of lines.

Depending on the resolution selected, the lines manifest themselves in different ways on the spectrum.

Buffer storage

The values that have been sampled are stored for 300 ms in the module's internal buffer and must be transferred during this time. (See ["Transferring characteristic values via Flatstream" on page 3097.](#))

The size of the buffer is constant and can store 8192 measured values. This results in the following relationship between the sampling rate and the duration of measurement.

Measurement duration = Buffer size / Samples per second

Since the number of values stored depends on the configured sampling rate and not the hardware-based sampling rate, not all values that are measured are stored. At a measurement duration of 318 ms, every second value is stored; at a duration of 15.9 ms, every hundredth value is stored.

The number of stored values can be set indirectly through registers ["MaxFrequencyEnvelope" on page 3085](#) and ["MaxFrequencyRaw" on page 3086](#)

Aliasing effect

The input signal is sampled at regular intervals. If the sampling rate used is too low, the input signal will be sampled incorrectly and a flawed image of the oscillation will occur. This undesirable phenomenon is called the aliasing effect.

To avoid such false results, the requirements of the theorem known as Nyquist's sampling theorem must be fulfilled in the sampling. This sampling theorem describes the necessary frequency ratio between the sampling and the signal and states that the sampling rate must be more than double the maximum frequency of the measured signal.

Example of incorrect sampling

Sine wave with 4 kHz sampled at 6 kHz. The red wave shows the sine wave measuring 2 kHz, which is a result of the sampling being too low.

Figure 221: Incorrect sampling with 6 kHz and 4 kHz

Information:

The module ensures that Nyquist's sampling theorem is always fulfilled.

With a wanted signal of 10 kHz, a reduced sampling frequency of 25.7812 kHz is used!

Resolution

The time-continuous input signal is converted into a series of discrete digital output values. The A/D converter resolution determines the maximum possible number of digital values. Since this is always a discrete number, digitization always results in a deviation from the actual input signal, which is known as quantization error.

The sampling rate determines the interval between 2 conversions and must be selected to suit the type of processing planned for the signal. For many signal processing tasks, it is fundamentally important to adhere to the sampling theorem. The module performs appropriate filtering and decimation steps to ensure that the sampling theorem is adhered to at all times, regardless of the configured sampling rate.

In the time domain, a higher sampling rate allows for a more detailed description of the signal but also consumes a larger amount of memory. In the frequency domain, a higher sampling rate increases the maximum frequency that can be evaluated. Since a defined number of values is used for the FFT, however, the resolution decreases and thus the possibility of distinguishing frequency ranges close to each other.

Information:

On the X20CM4810, a MaxFrequency of 200 Hz results in a distance of 0.0629 Hz between 2 lines.

Time signal

The resolution can be identified in the time signal from the distance between 2 adjacent measurement points.

Example

MaxFrequencyRaw is 2 kHz in this example.

Figure 222: Time signal with corresponding resolution

Frequency spectrum

The resolution in the frequency spectrum indicates the distance between the individual frequency lines (spectral lines) that can still be evaluated.

Example

Frequency spectrum at a MaxFrequency of 2 kHz.

Figure 223: Frequency spectrum

Quantization

To process analog signals digitally, an analog-to-digital converter (AD converter) is required. However, only voltages in steps can be measured by an A/D converter. This is known as quantum voltage. The range to be measured is thus quantized.

In an AD converter, the digital resolution depicts the number of levels there are in the quantization. This determines the accuracy and sensitivity with which a previously analog level value is depicted. The more available levels there are, the more precise the discrete signal received and the higher the sensitivity of the measurement.

The resolution indicates how many varying digital values an analog signal can be converted into. The resolution is expressed in bits.

| | |
|-------------------|-------------------------|
| 8-bit resolution | 256 level values |
| 16-bit resolution | 65,536 level values |
| 24-bit resolution | 16,777,216 level values |

Example

A 24-bit resolution, a sensor measurement range of ± 10 V and a sensor sensitivity of 100 mV/g result in:

$$20 \text{ V} / 2^{24} = 1.192 \text{ } \mu\text{V} \rightarrow \text{Corresponds to } 11.92 \text{ } \mu\text{g}$$

Figure 224: Quantization error at low resolution

Information:

The module has 24-bit resolution.

Duration of measurement

The duration of measurement depends on the configured maximum frequency. Depending on whether the envelope or raw values are to be measured, the following registers are used for configuration:

- "MaxFrequencyEnvelope" on page 3085 for envelope measurement
- "MaxFrequencyRaw" on page 3086 for raw value measurement

| Maximum frequency | Sampling frequency | Duration of measurement |
|-------------------|--------------------|-------------------------|
| 10000 Hz | 25781 Hz | 0.3178 s |
| 5000 Hz | 12891 Hz | 0.6355 s |
| 2000 Hz | 5156 Hz | 1.5888 s |
| 1000 Hz | 2578 Hz | 3.1775 s |
| 500 Hz | 1289 Hz | 6.3550 s |
| 200 Hz | 516 Hz | 15.8875 s |

Envelope

When you look at the various causes of oscillations, it becomes clear that they primarily come from 2 sources:

1. Imbalance and misalignment

Imbalance and problems with alignment lead to predominantly harmonic, sinusoidal oscillations.

Figure 225: Imbalance - Harmonic oscillation

2. Impacts

Many types of machine damage can result in oscillations that cause the structure of the machine or adjacent machine parts to vibrate at their natural frequency. Impact-related causes of this are a result of corrosion, a rotor brushing up against the machine housing or roller bearing/gearing damage to the gears.

In the case of roller bearing damage, impact occurs when either the rolling elements roll over damage on the inner or outer track or when one of the rolling elements themselves is damaged.

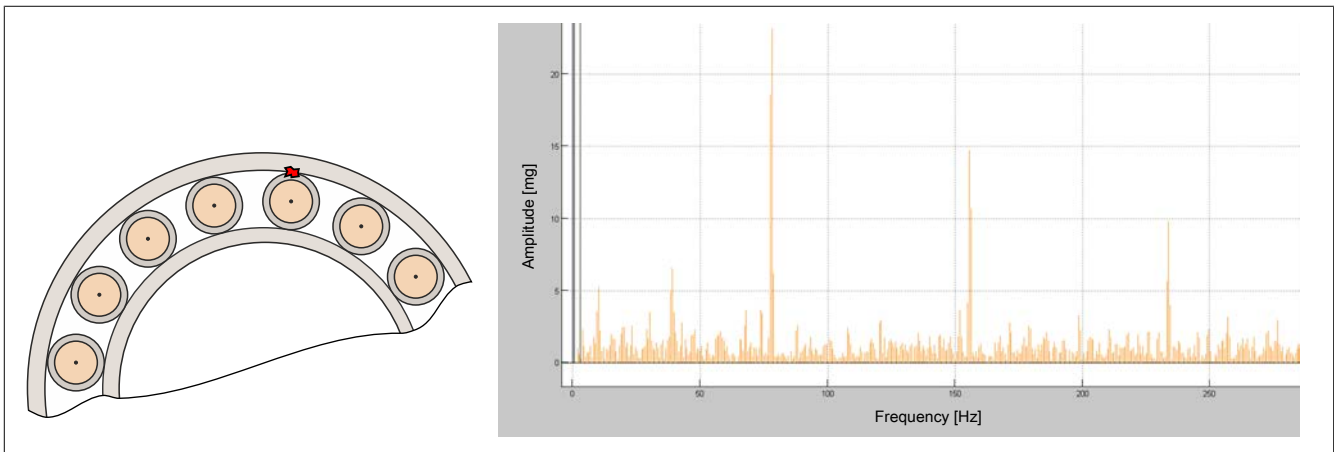

Figure 226: Bearing damage - FFT of envelope signal

This kind of impact can be compared to a clapper hitting a bell. If the bell is struck 2x per second, it vibrates at its natural frequency and not 2 Hz. The natural frequency is determined by the constructive design and material properties. As with any sound boxes, mounting also factors into this.

If the damage is to the roller bearing track, every shock pulse will lead to a corresponding reaction in the vibrating system. It is only practical to measure the sum of all pulses, i.e. the total signal.

In the case of damage to roller bearings, the bearing rings are the first to start vibrating.

Analyzing oscillations

Oscillations are transmitted in the machine as waves and can be measured on the machine's surface. A prerequisite, of course, is that a path is available for the sound transport, i.e. there are no sound-absorbing border crossings such as air, rubber, etc. between the roller bearing and sensor.

This signal can be measured on the surfaces of the machine by means of an accelerometer. The signal is made up of a variety of oscillations and impacts that overlap each other. When considering the time signal in this way, it is easy to see that allocating individual frequencies is difficult, if not impossible.

Using a Fast Fourier transform, this time signal can be converted to give the natural frequency of the system. These are in the high-frequency range. The rotor frequency and its harmonic frequency are clearly identifiable as the dominant frequency portion.

The rollover frequencies of the roller bearings are between 15 and 70 Hz at a speed of approximately 600 rpm, depending on the bearing.

In particular, shock pulses of a lower intensity, as they are when damage first begins, can barely be noticed or assessed. It is only when there is advanced damage to bearings that signal peaks can be clearly observed.

Figure 227: Advanced bearing damage at 600 rpm

To make the actual result, or shock sequence, clearly visible, it is obviously not enough to simply provide the amplitude spectrum. It is much more important that the process of convolution that took place when the signal occurred be appropriately reversed so as to separate the excitation function from the natural frequency. This is what envelope analysis provides.

An amplitude-modulated signal is made up of a high-frequency carrier signal and a low-frequency wanted signal. The amplitude of the carrier signal changes depending on the wanted signal. In the receiver, the wanted signal is extracted from the carrier signal by the formation of the envelope curve (demodulation).

In the case of machine resonances caused by periodic impacts, the machine resonances can be viewed as the carrier signal and the low-pass-filtered shock pulses can be viewed as the low-frequency modulation signal. Demodulation results in the shock pulses being extracted from the resonance frequencies.

Envelope analysis

Normally in an envelope analysis, the frequency spectrum of the envelope signal is evaluated. Suppressing the steady component gives a frequency spectrum that exhibits only one increased amplitude at the frequency of the low-frequency sinusoidal oscillation.

The envelope signal of the periodically peaked excited machine resonance shows mostly increased amplitudes in the shock pulse repetition rate and its multiples.

The envelope analysis is thus a method for differentiating between harmonic causes (imbalance, orientation) and impact-related causes (roller bearing damage, gearing damage, etc.).

Conversely, it must be stated that harmonic causes in an envelope spectrum cannot be determined accordingly.

Figure 228: Time signal with envelope

Figure 229: Resulting frequency spectrum of the envelope

Displacement, velocity and acceleration

Sensors can record oscillation acceleration, oscillation velocity or oscillation displacement. Regardless of the physical value that the sensor records, the oscillation can be represented as a combination of acceleration, velocity or displacement since:

$$s = \int v dt = \iint a dt^2, \text{ or } a = \frac{dv}{dt} = \frac{d^2s}{dt^2}$$

Legend:

- s - Oscillation path
- v - Oscillation velocity
- a - Oscillation acceleration
- t - Time

Since oscillation velocity is calculated through integration from the oscillation acceleration and oscillation displacement is calculated through integration from the oscillation velocity, it is possible to convert the sensor value whenever necessary.

Acceleration is proportional to the force. In contrast, the velocity is an indication of the energy.

What is significant from a practical standpoint is that, when one physical value is converted to another, the frequency is included. For a sinusoidal oscillation, the following applies:

$$s = \frac{a}{(2 \cdot \pi \cdot f)^2} \quad v = \frac{a}{2 \cdot \pi \cdot f}$$

The frequency is in the denominator. As a result, high-frequency signal portions are underestimated when using oscillation velocity in comparison with oscillation acceleration. This effect is squared with the application of oscillation displacement.

9.26.7.16.2.3 Determining limits and alarm limits

A general statement about the health of a machine can be made by comparing the measured characteristic values with limit values defined by standards (e.g. ISO 10816) or by the manufacturer of the machine.

Characteristic values are calculated from the measured signals, which are representative of the status of the system at the given measurement point.

Norms can be used in part to determine alarm limits. In addition, limits can be set based on the machine's history and the experience of the operator.

Comparison with references and norms

For certain machines and systems, limits are fixed by norms. With the exception of ISO 10816, these give little information for assessing the actual status of the machine.

Manufacturer's limits

A few machine manufacturers give limits for permissible oscillations and other relevant factors for assessing the status of the machine. These are based partly on calculations as well as the manufacturer's own knowledge and experience.

Whenever possible, these are the limits that should be used for assessing condition.

Operator's limits - Experience-based values

Operators can also draw on their own experience when assessing the status of the machine. Long-term observation of the characteristic values and the machine's history can provide relevant values based on experience.

The limits ascertained from this can vary significantly from limits set by norms and those prescribed by the manufacturer of the machines. This assessment is only possible when operators have considerable experience with oscillations in the machine and are in a position to differentiate between positive and negative characteristics.

When determining limit values, it is important to note that vibration measurements are influenced by factors such as:

- The location of the damage
- The location of the sensor
- The speed of the moving parts of the machine
- The load on the machine parts

Assessing the trend

In many cases, not enough is known about the actual behavior of a machine during operation, in particular when there is damage.

To make a reliable statement about its condition, the chronological sequence of the characteristic values (characteristic value trend) must also be used when making the assessment.

In the progression of the trend, the "Normal condition" is the starting point. The reference level (normal level) is the level of the characteristic value as set in the normal condition.

Changes in the trend are observed with the normal condition as the starting point. When there is damage, the relevant characteristic values in each case generally increase, although a decrease can also be an indication of a problem in the system.

In order to assess trends accurately, it is essential that the characteristic values of the oscillations are always recorded under the same operating conditions and always classified in the same way. In particular, the speed and load ratio have a strong effect on the characteristic values. Increases in trends under differing operating conditions cannot necessarily be a sign of a change in the actual condition. In many cases, trend observation can assist in monitoring the condition of the machine and bearings.

Figure 230: Typical trend progression

The first and second derivatives of the damage progression trend line can provide good information about how badly a component is damaged.

Example

This example will use the first and second derivative to determine the best time for repairs. The maximum service life will be taken into account when selecting a time to perform a replacement. The possibility of lowered production quality is not taken into consideration.

Various times for performing a replacement can be selected by referring to the trend progression.

- k1 = First increase. Very conservative, service life is wasted.
- k2 = Second increase. Good compromise between conservative and optimal.
- k3 = Drop in second derivative. Optimal utilization of service life.

Information:

This example of derivative usage is not permitted to be used as a rule in your own applications.

First derivative

Figure 231: First derivative of the trend progression

Second derivative

Figure 232: Second derivative of the trend progression

Dynamic speed change

With the resulting FFT calculation in the module, it is assumed that the frequency spectrum and the resulting lines do not shift during the time it takes to calculate a data buffer. For shafts, this is only the case when they are running at a constant speed.

In the case of dynamic speed, narrow-band frequencies cannot be used to monitor or analyze damaged frequencies since these do not give valid results.

The following example shows the effect of variations in shaft speed on the resulting frequency spectrum during FFT calculation.

Example

The speed of a shaft changes from 100 Hz to 200 Hz.

Figure 233: Speed profile

Changing the speed of a shaft
(Within one buffer measurement length.
Damage is simulated with the speed frequency.)

Figure 234: Time signal

Change in the time signal

Resulting spectrum
calculated from the time signal

Figure 235: Invalid result in the frequency spectrum

Possible approaches to measuring in a dynamic system

- **Best solution:** Adopting separate measurements for trend analysis where the speed can be kept constant for the duration of measuring.
- If a measurement cannot be taken at constant speed, an assessment of the machine condition can be made using the characteristic values or a broadband frequency (in this example, this would be 80 to 220 Hz).

9.26.7.16.3 Practical applications of damage recognition

It is possible to gain good insight into the condition of a machine or system by measuring the parameters associated with errors. This parameter data is used by different algorithms in the module to calculate the characteristic values. This method of forming characteristic values occurs continually and automatically. It requires little technical knowledge and is easy to use and implement. It is an easy way to check a machine for damage and error states.

Selecting suitable characteristic values and assessing them over a longer time frame is the basis for effective and successful monitoring of a machine, a process known as "trending". It enables multiple aggregates to be monitored with a relatively low need for technical measuring and a low demand on staff.

Simply setting basic limits as a warning is not enough. Instead, logical correlations with other parameters such as load or speed, or even the shape of the trend curve, are also required.

Characteristic values are thus gathered in the trend curve and compared with norms or values taken from available experience over a long period of time. This trend progression can be used to make a good assessment of the machine's condition. The way these factors change over time indicates whether the condition is worsening, i.e. if damage is beginning to occur.

Recording the measured values in a diagram over a longer period of time shows the status of the characteristic values at the defined warning and alarm thresholds. If these thresholds are exceeded oscillation diagnostics gives the cause of the error so that appropriate maintenance measures can be taken.

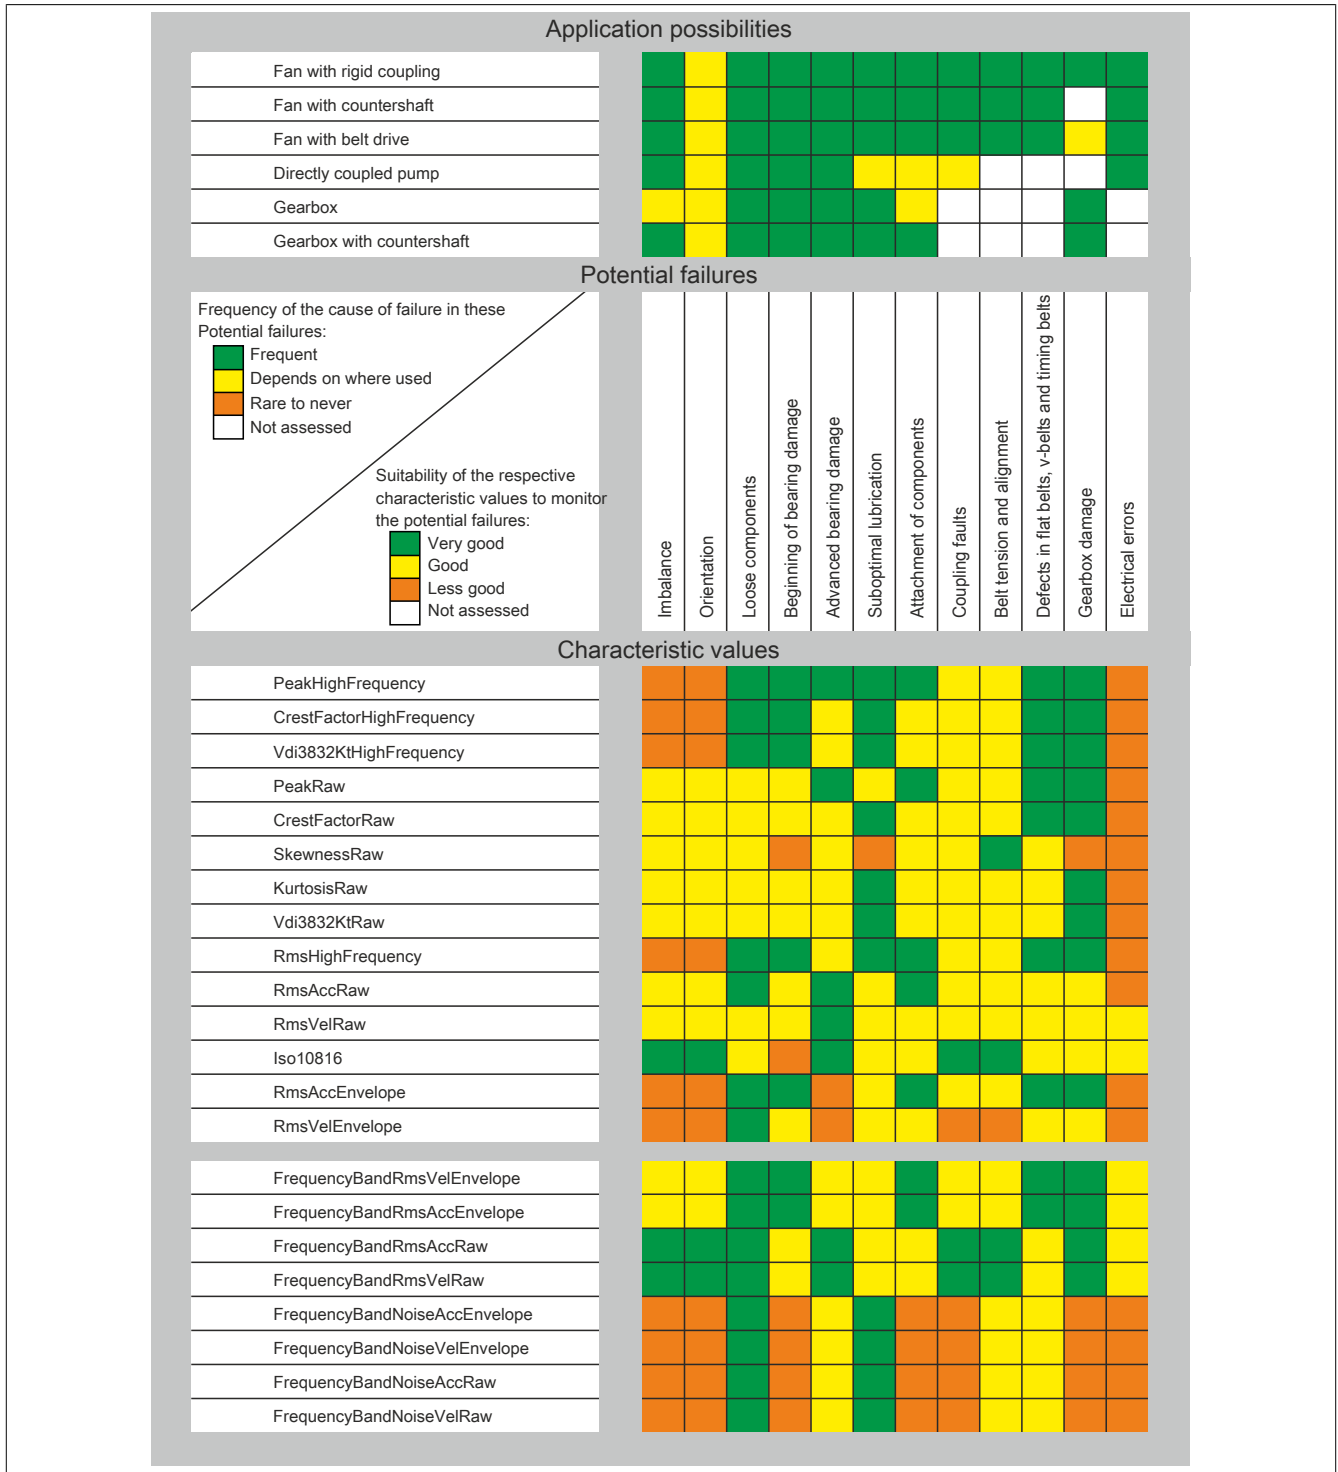

Example: Trend curve for a characteristic value

9.26.7.16.3.1 Characteristic values

The following matrix shows the relationship between potential failures and the suitability of the characteristic values provided in the module for error analysis. The potential failures refer to the individual application possibilities.

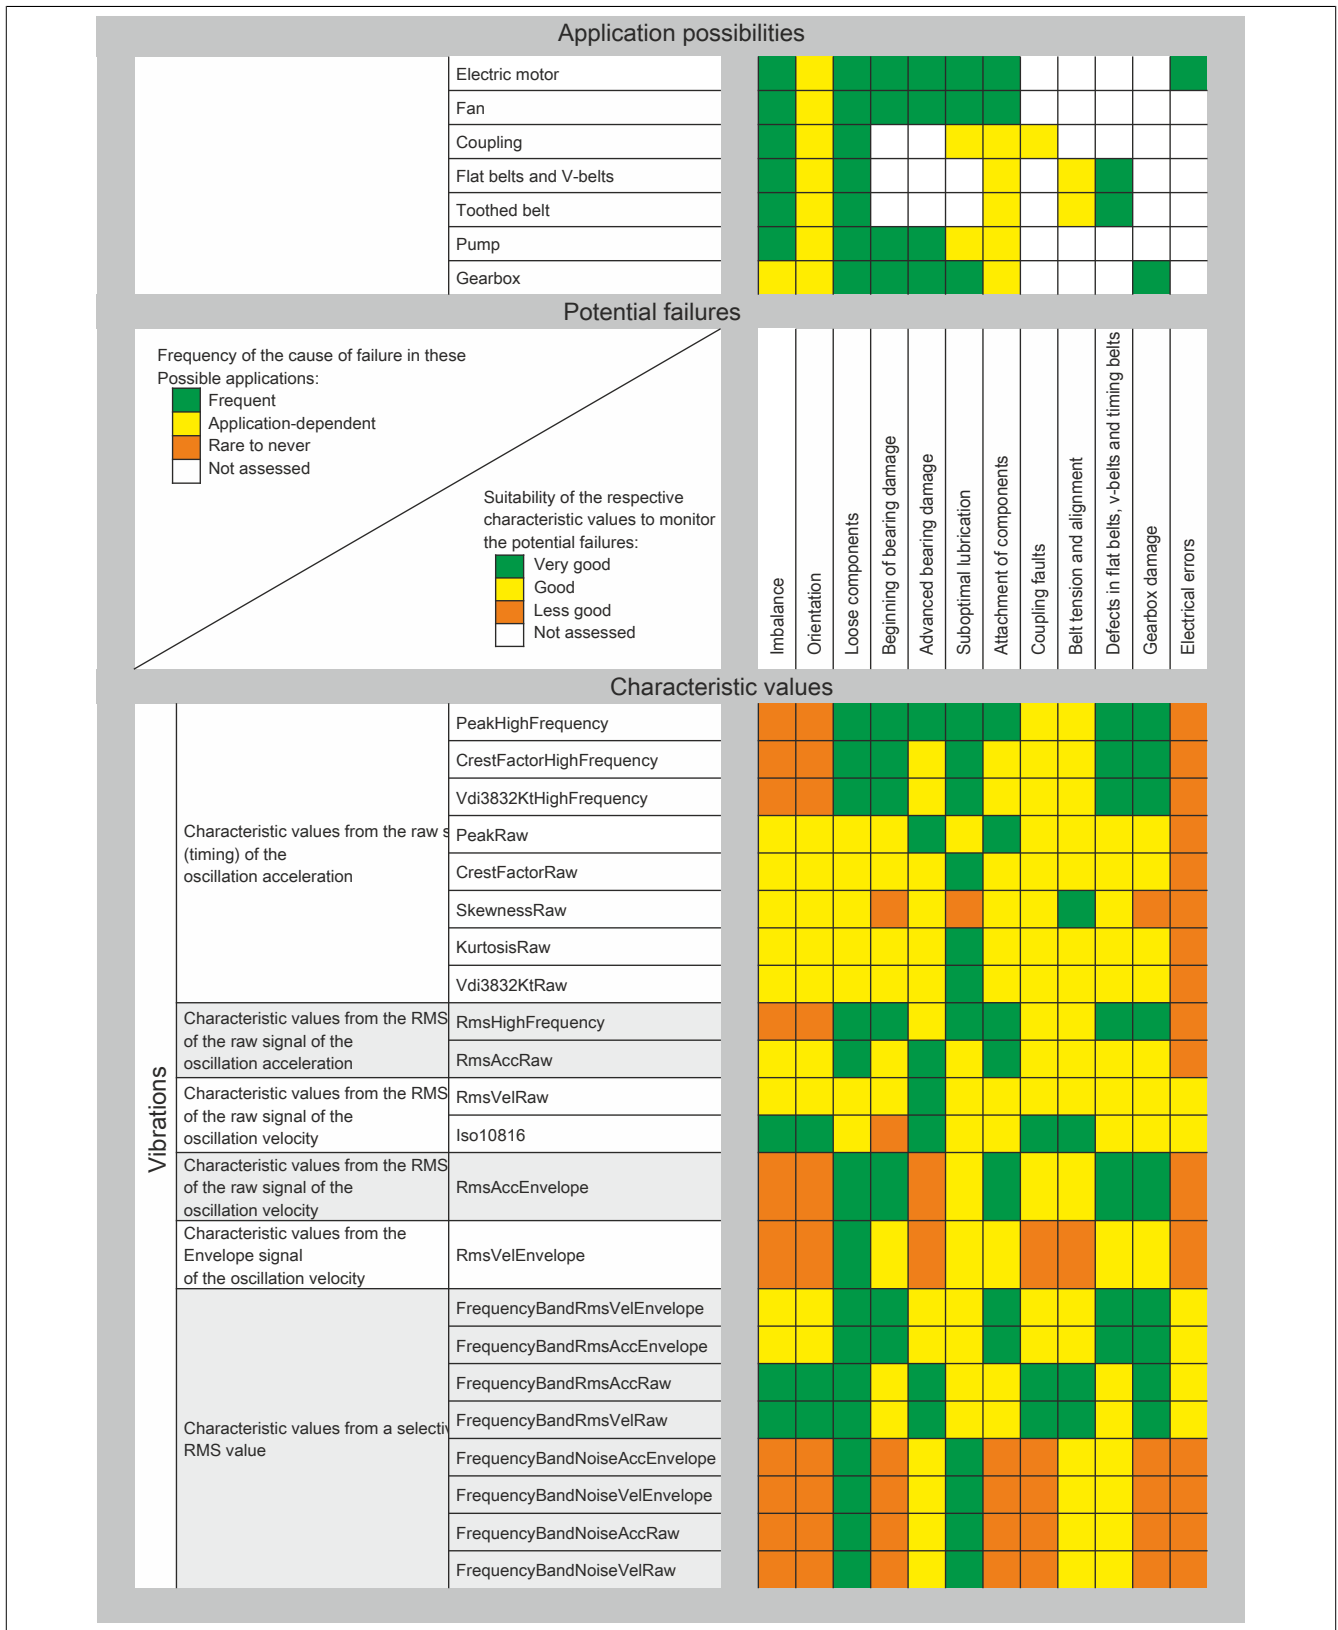

This assessment is based on an estimation of typical applications.

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

9.26.7.16.3.2 Potential failures

The effect of damage on the oscillation behavior depends on the type and extent of the damage. For this reason, it must be assessed on a case-by-case basis.

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Imbalance

The term imbalance refers to rotating bodies with a mass that is not rotationally symmetrical. In other words, the center of mass is not on the axis of rotation

Figure 236: Representative sketch of an imbalance

Imbalance leads to vibrations and increased wear, particularly at high speeds, which is why counterweights are applied to compensate for this as counterbalance. In practice, it is very rarely possible to fully compensate for this, meaning every rotating body has some residual imbalance.

The centrifugal force caused by imbalance is dependent on the square speed and thus has a more significant effect at higher speeds (higher speed frequency). On a spectrum, therefore, the frequency line denoting speed is significantly higher.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|--------------|----------------------------------|--------------------------------|--|
| Imbalance | $1 \times f_n$ | - | Only severe imbalance causes peaks in the speed that show up in the envelope spectrum. |

f_n ... Nominal speed

Information:

The module can only measure the intensity of the imbalance, not its position on the shaft. For this reason, it cannot be used for balancing.

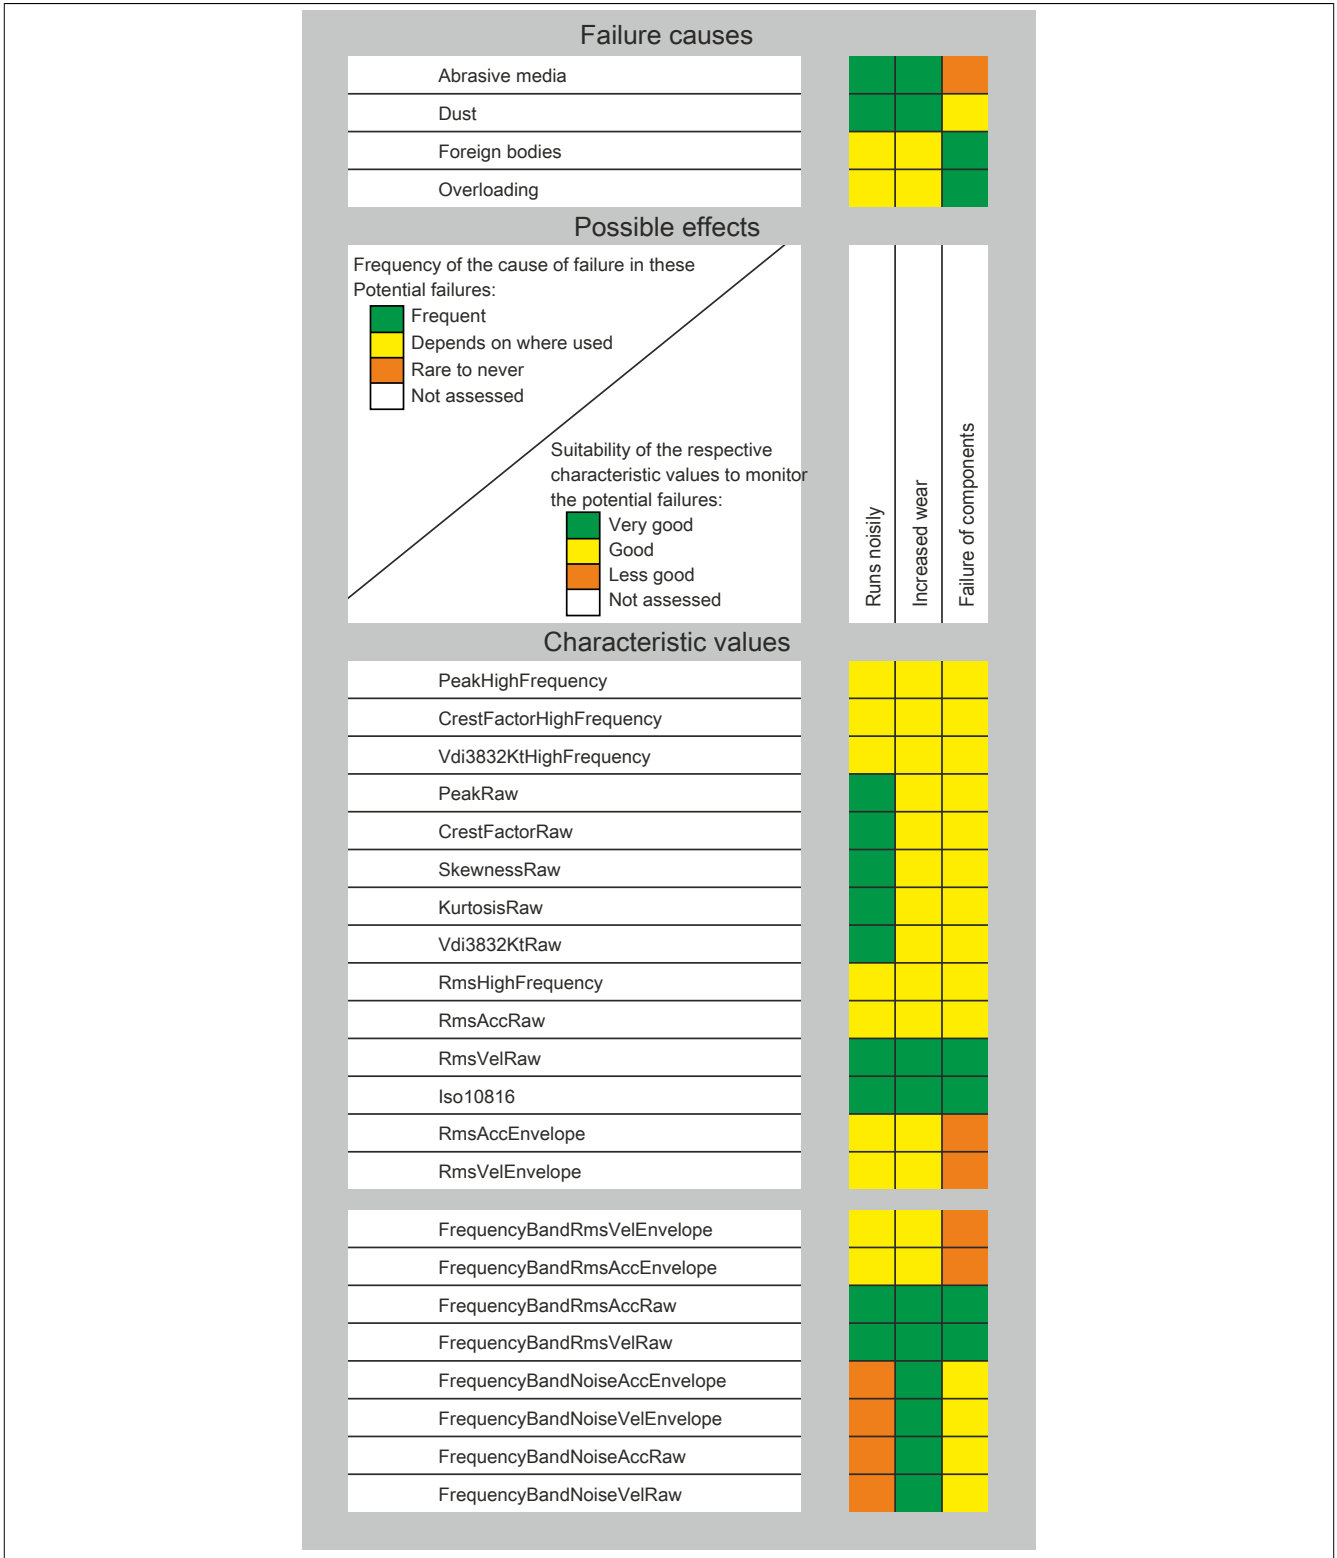

Figure 237: Failure causes and effects of imbalance

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Misalignment

During operation, a number of different factors can cause machine parts to fail to align or stop aligning with each other.

Shafts should rotate around a linear axis at the coupling positions, so that the restoring forces at the coupling position and the loading forces in the bearings are kept as low as possible. Misalignment causes increased vibrations and wear.

Misalignment usually consists of a parallel and an angular misalignment. In the event of a severe parallel misalignment, strongly increased values can be observed in the area of double speed.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|--------------------------|--|--------------------------------|---|
| Misalignment in coupling | 1 x fn, 2 x fn (sometimes 3 x fn, 4 x fn) | - | With parallel misalignment, usually only "1 x fn" occurs. |

fn ... Nominal speed

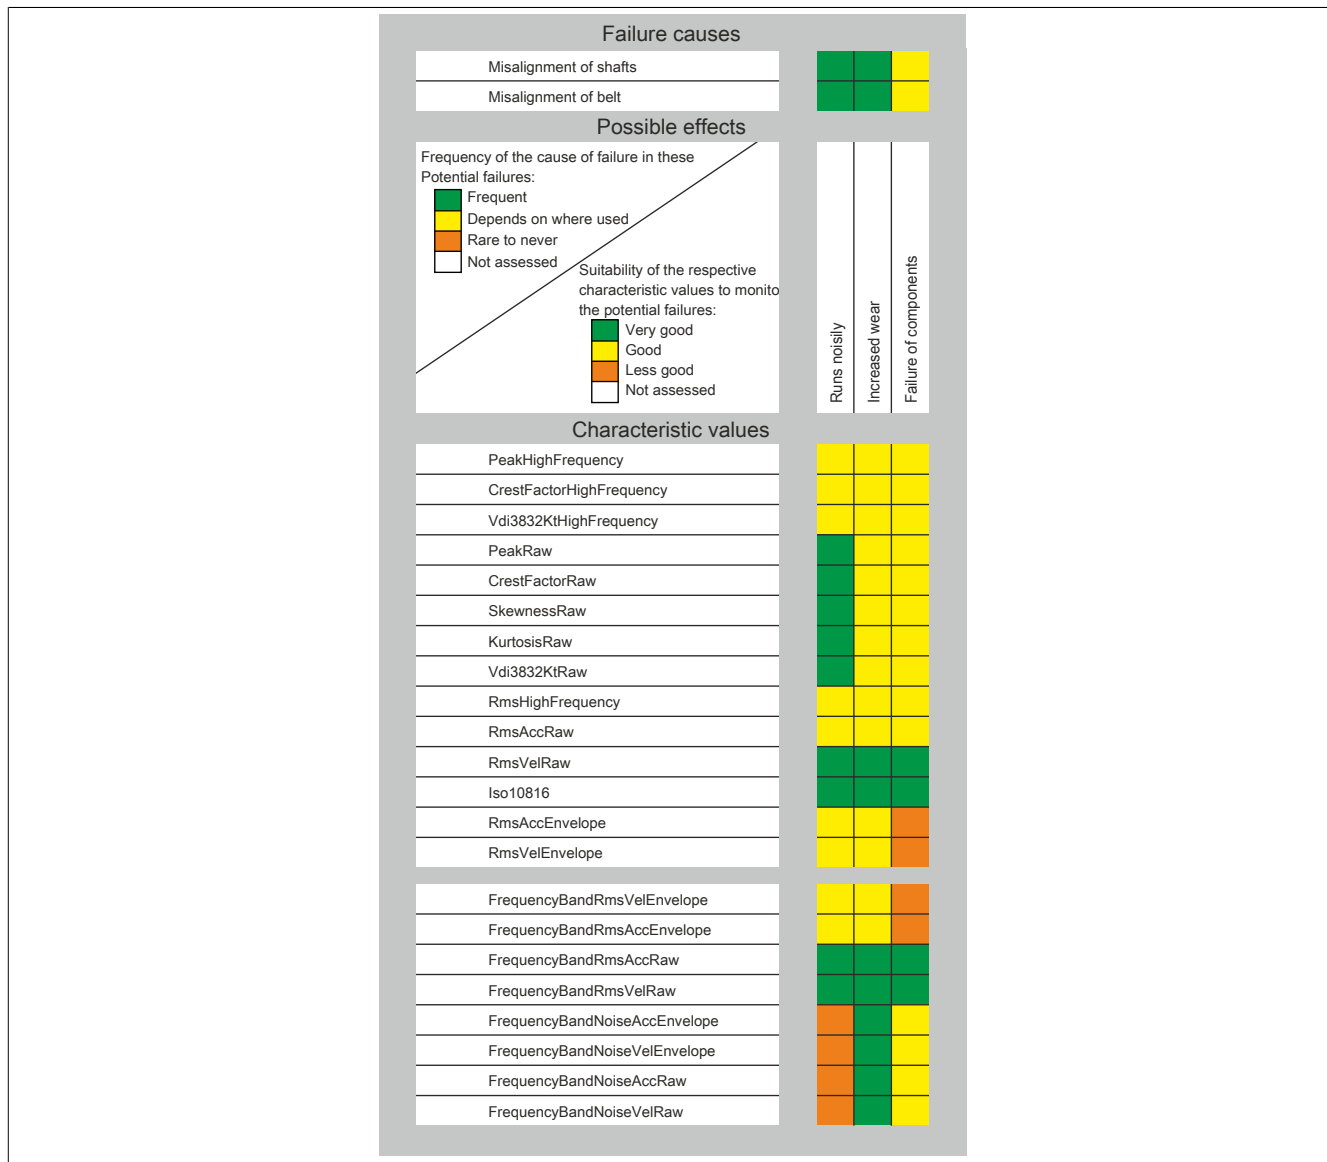

Figure 238: Failure causes and effects of an alignment failure

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Belt damage

Belts often cause various problems during operation. A belt can be damaged if the tension is too low or too high or if the belt is incorrectly aligned. If the damaged belt part rolls over the pulley, this causes impacts that can be measured.

Flat belts and V-belts

With flat belts and V-belts, torque is transferred between the belt and the pulley through the contact surface. Belt drives are not very sensitive with regard to alignment but nevertheless lead to vibration development and above all to increased wear and energy consumption if the deviation is too high.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|----------------|----------------------------------|--------------------------------|---|
| Defective belt | 1 x fr, 2 x fr, 3 x fr ... | 1 x fn1, 1 x fn2, 1 x fr | Belt frequencies usually occur in both spectra. |

fr ... Belt speed

fn1 ... Nominal speed of shaft 1

fn2 ... Nominal speed of shaft 2

Poorly aligned or incorrectly tensioned belts can also cause severe stress on the bearing points. The increased vibration also causes heavier wear on belts and pulleys.

The vibrations are clearly identifiable at the bearing points of the individual shafts.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|----------------------|----------------------------------|--------------------------------|---|
| Misalignment of belt | 1 x fn, 2 x fn 1 x fr | 1 x fn | If the belts strike against the pulley laterally, impacts can also occur with speed and belt frequency. |

fn ... Nominal speed

fr ... Belt speed

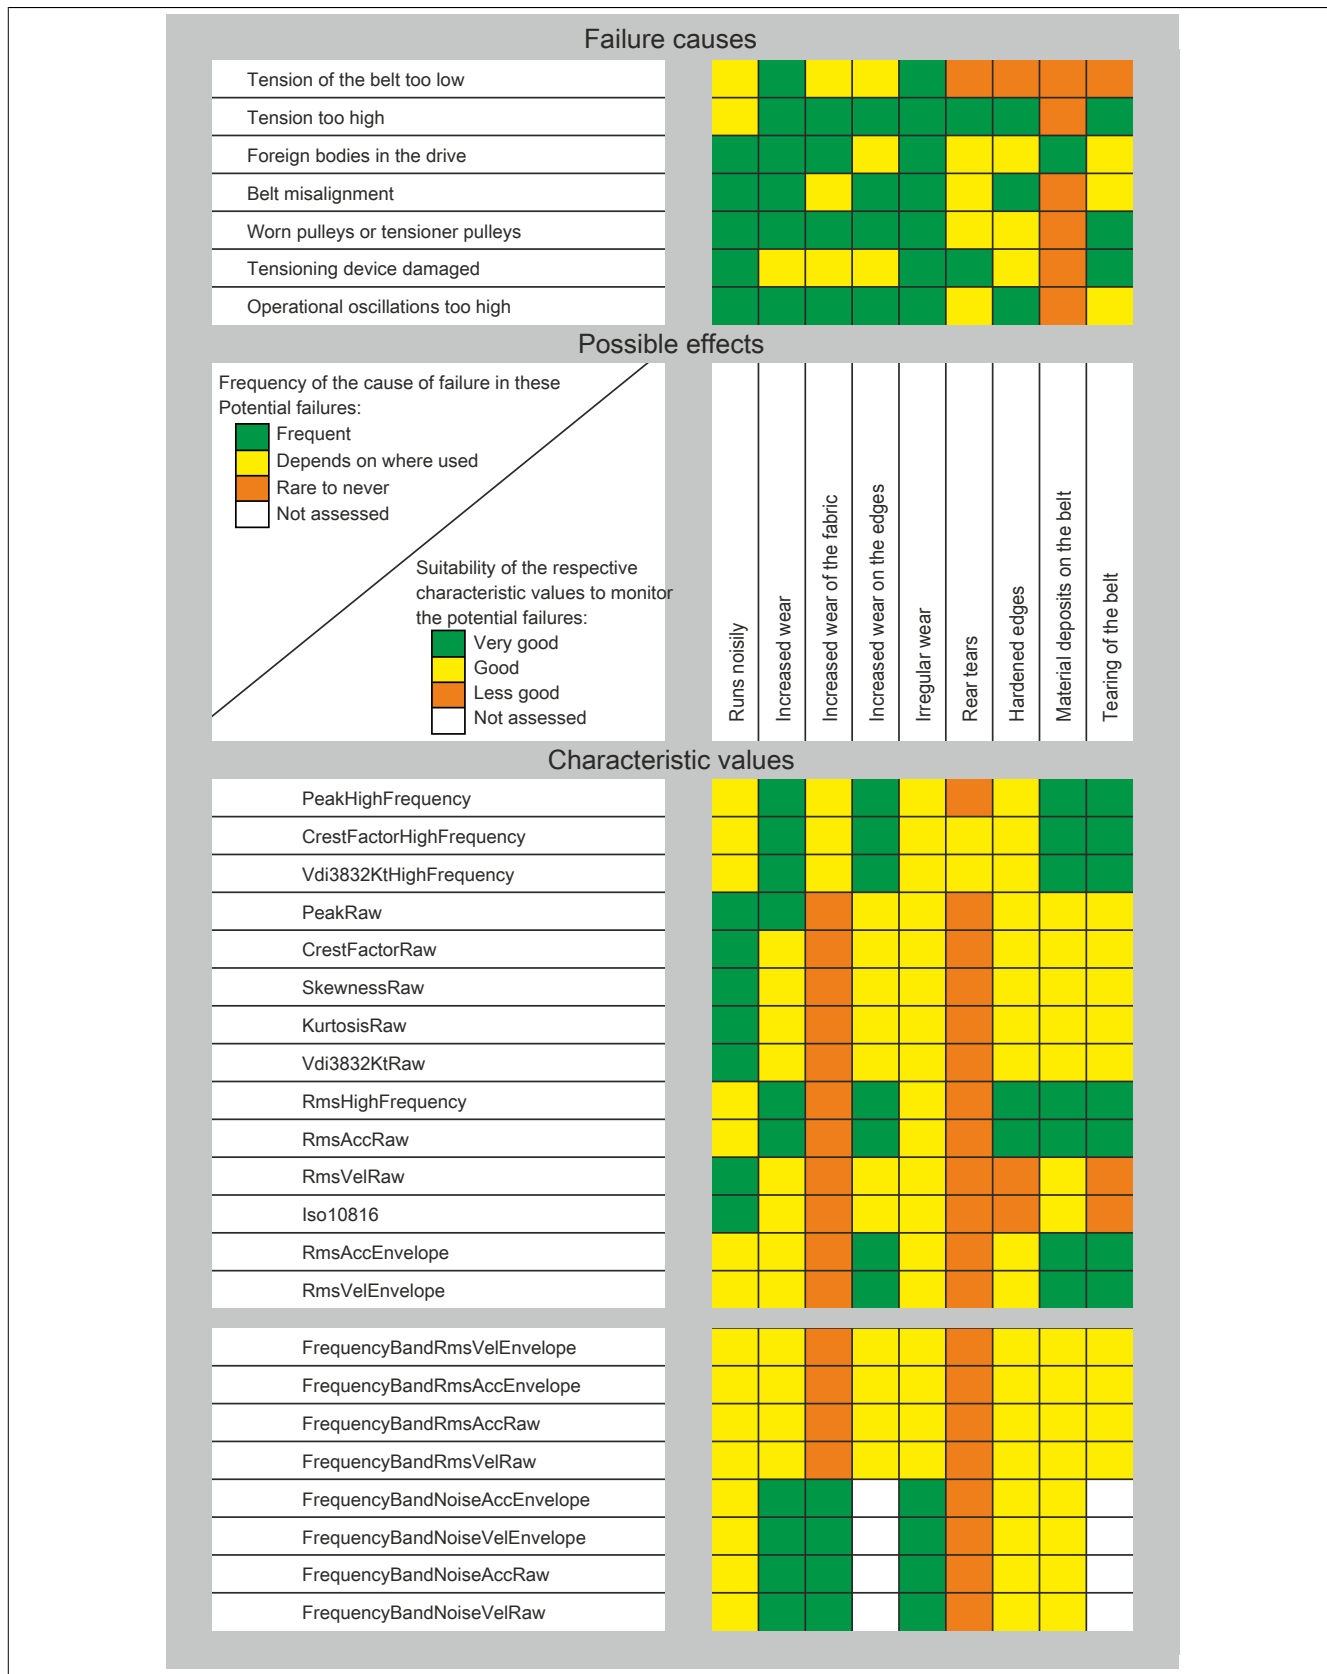

Figure 239: Failure causes and effects of belt damage in flat belts and V-belts

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Toothed belt

With toothed belts, torque is transferred via the meshing of the teeth. In addition to the already known failure causes, there are also the failures caused by the toothing.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|---------------------|----------------------------------|--------------------------------|---|
| Toothed belt damage | 1 x fr | 1 x fr, 1 x fzn | The tooth meshing frequencies in combination with the respective speed are clearly visible. |

fr ... Belt speed
fzn ... Meshing frequency

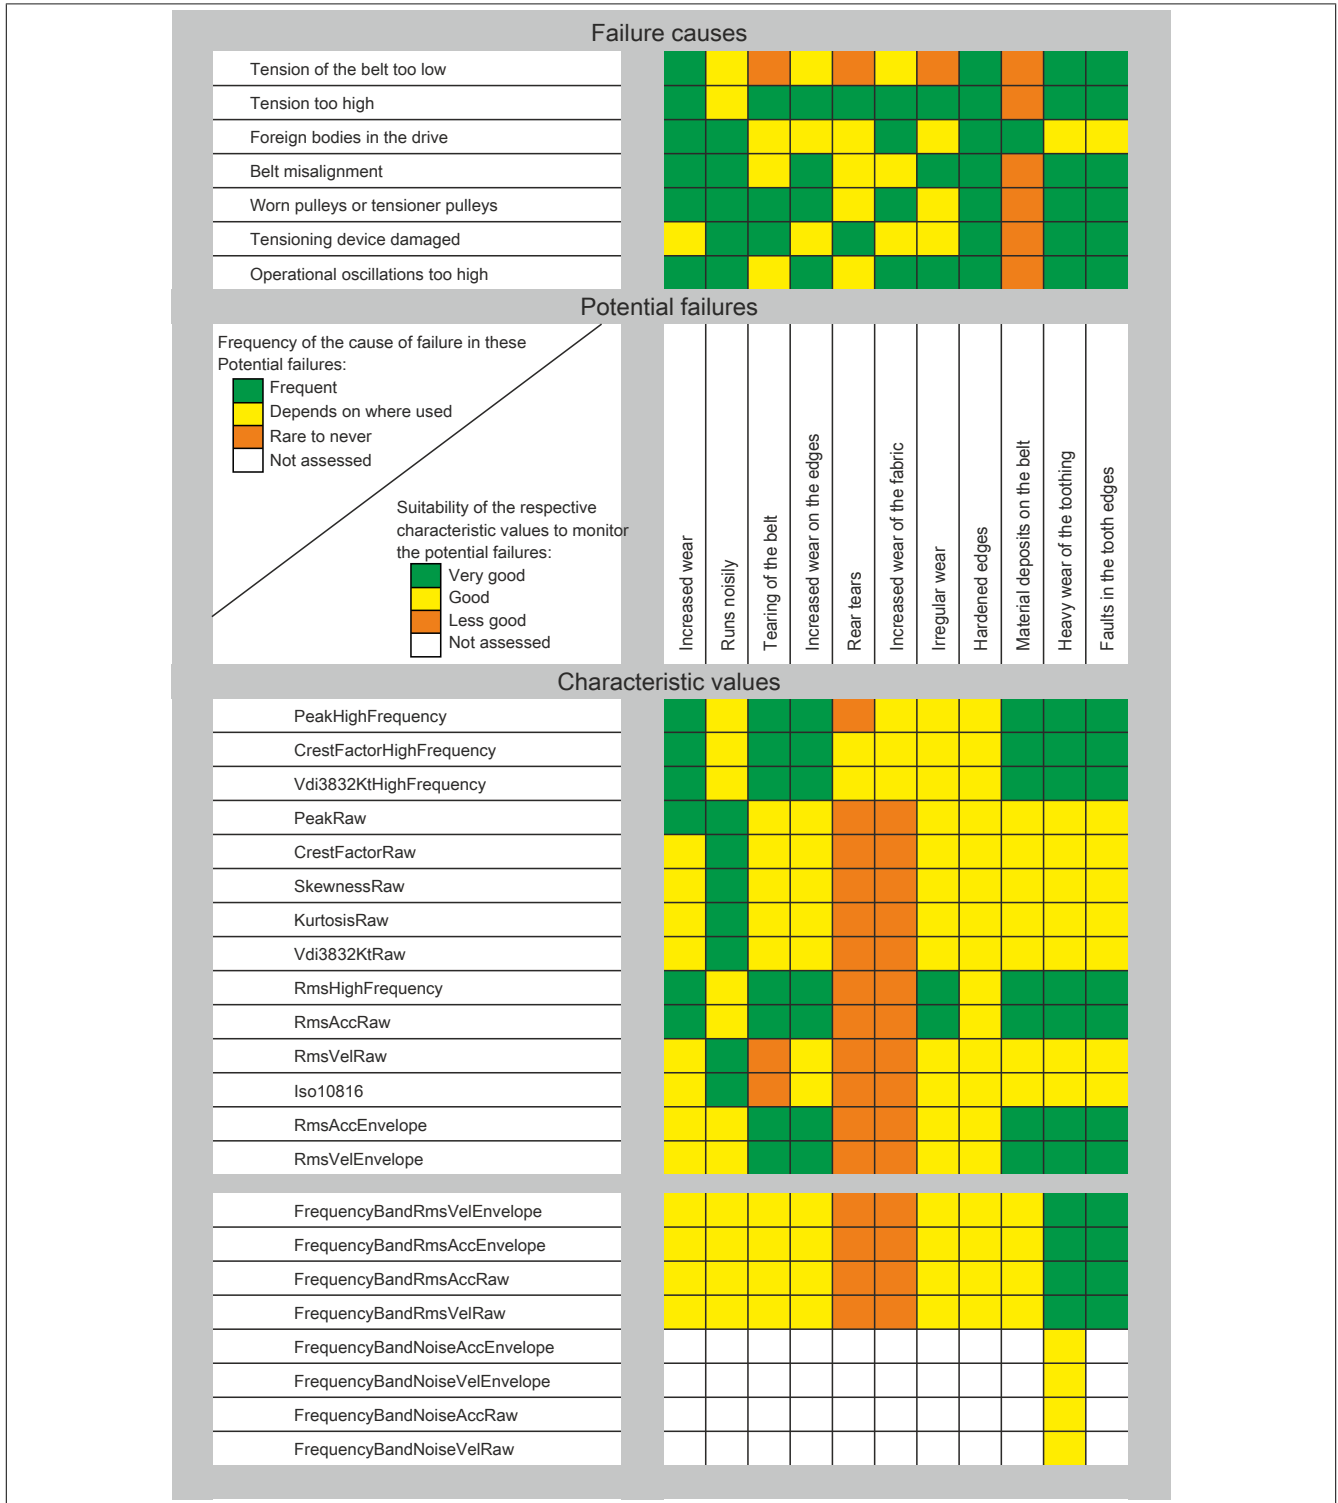

Figure 240: Frequency of failure indicators on toothed belts

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Loose or striking parts

If individual parts in the machine are loose, they can cause unwanted oscillations. When individual parts strike housings or attachment parts, these appear very similar. As a result, the two causes of damage cannot be analyzed separately.

In addition, components strike their counterparts on each revolution. This in turn causes the attachment parts to vibrate at their natural frequency. Envelope analysis can be used to separate the causes of impact.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|--|----------------------------------|--------------------------------|---|
| Loose parts, parts striking each other | (1 x fn) | 1 x fn | There is usually one strike per revolution. If an envelope occurs for the load, a double frequency can be determined. |

fn ... Nominal speed

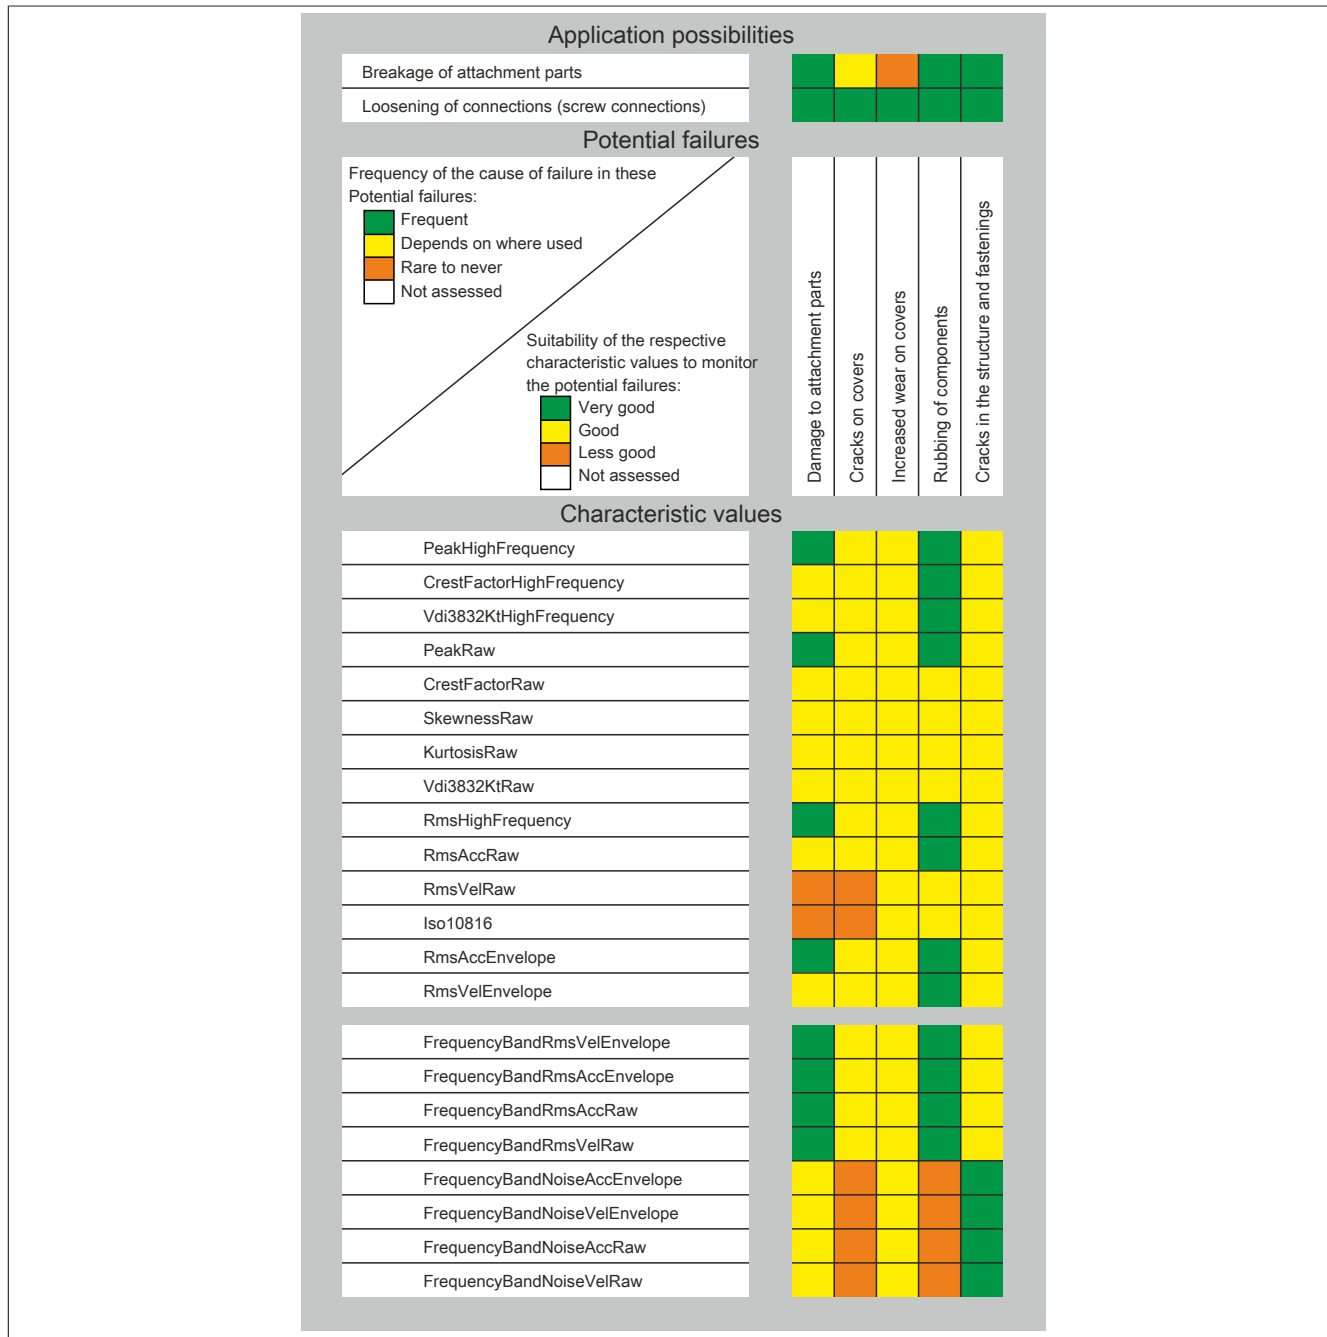

Figure 241: Failure causes and effects of belt damage

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Slide bearing damage

In a structure-borne sound measurement, the typical damage frequencies for a slide bearing do not manifest themselves until a very late stage. For this reason, this method is less suitable for early detection.

Roller bearing damage

Many types of bearing damage are caused by imprecisions in the bearing surface such as material damage or micro-cracks. These pittings (i.e. material damage or micro-cracks) are rolled over by the roller elements cause impacts on the roller bearing and its attachment parts.

Figure 242: Roll-over processes in the bearing

The mechanism is very similar to the striking of a bell: The clapper strikes the body of the bell, and the bell starts vibrating at its natural frequency.

In the case of the bearing, each time the roller moves over the damaged area it is like the striking of the clapper, and the roller parts and attachment parts start to vibrate.

These very small oscillations can be measured as a modulation or superposition of the excitation frequency on the surface of the bearing.

Appropriate analysis methods such as formation of the envelope can separate the superposition to make the roll-over frequencies of the bearing clearly discernible.

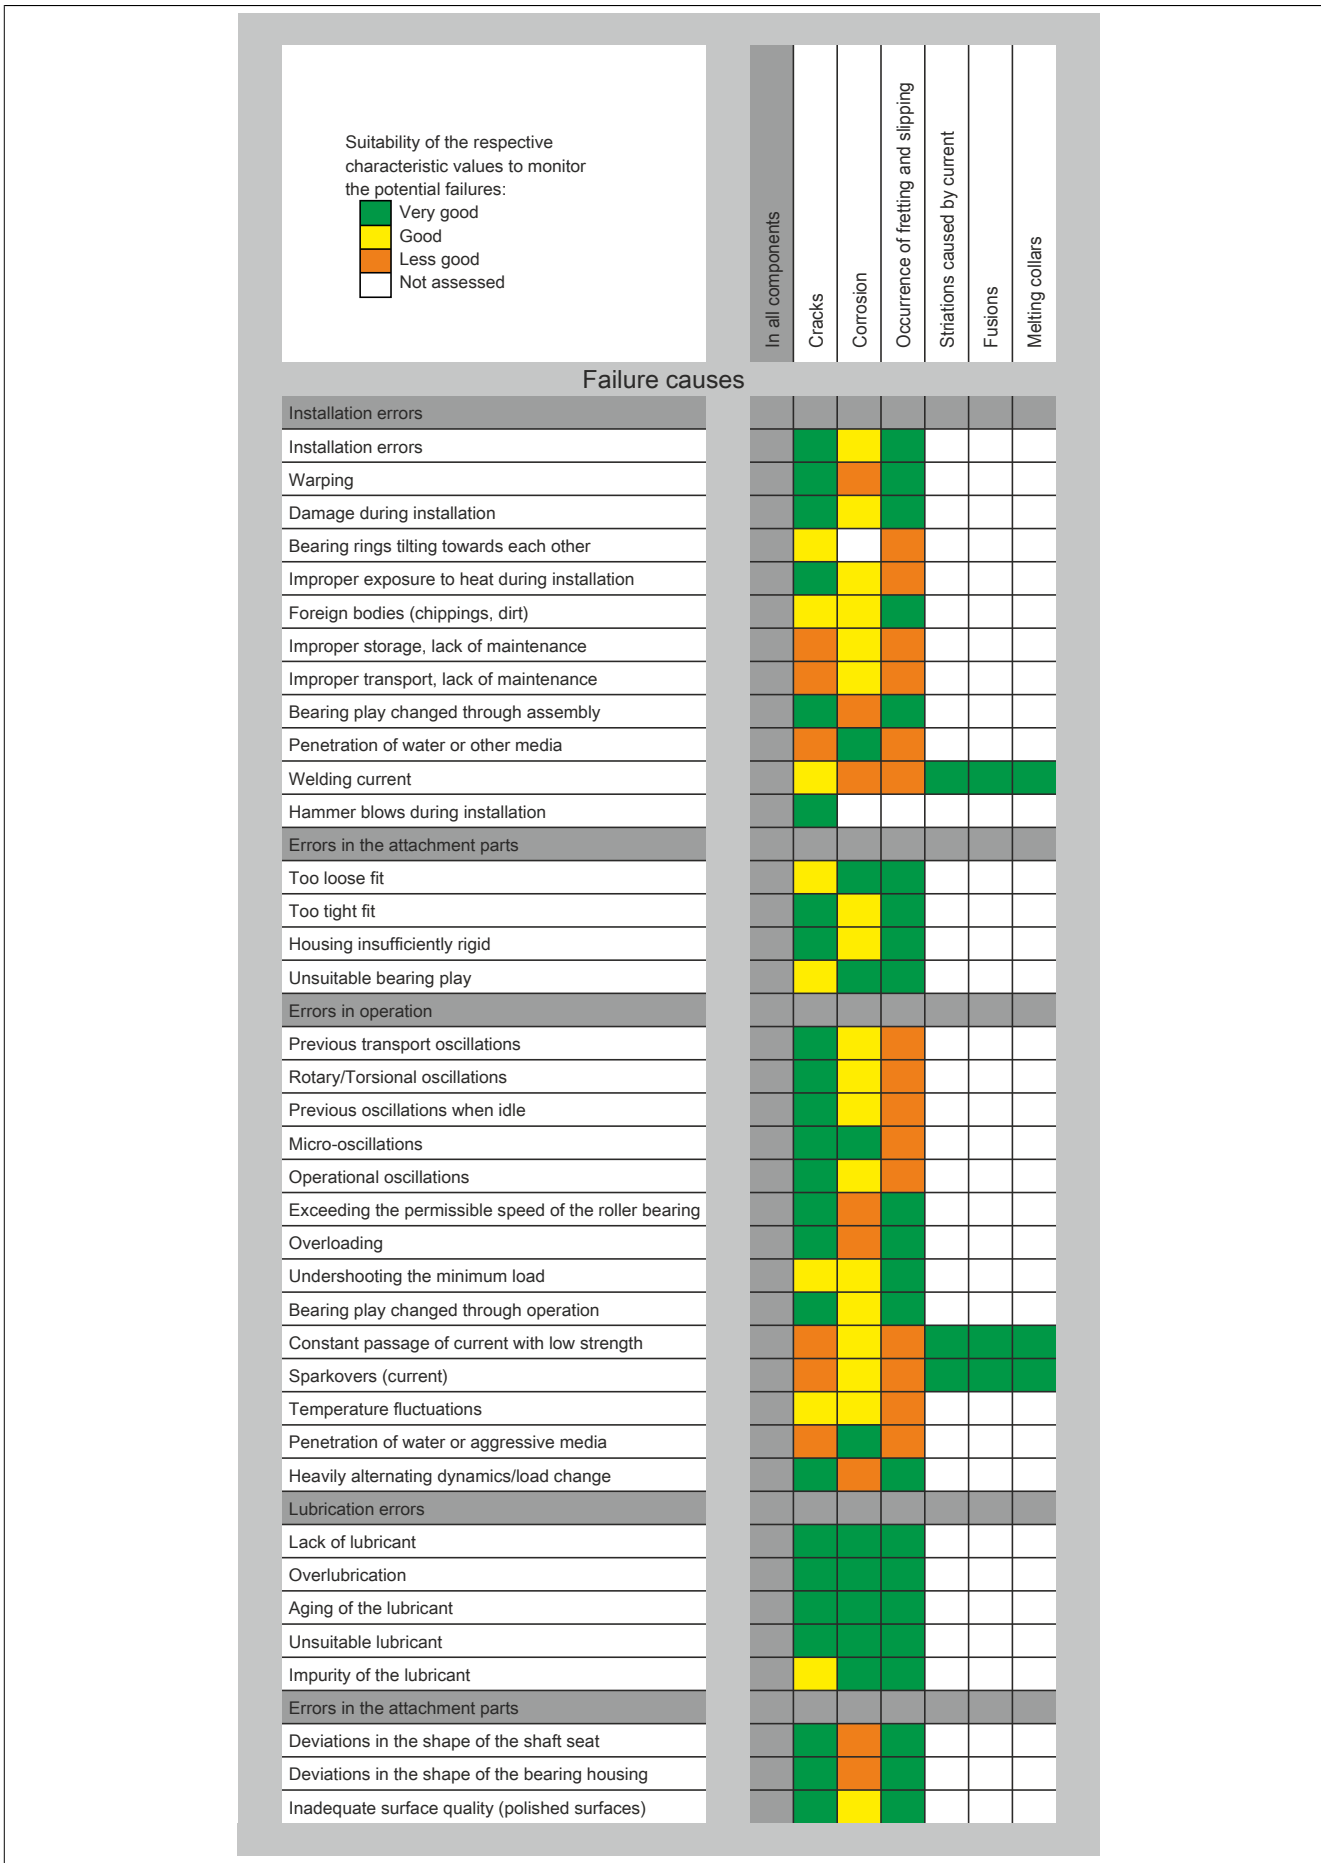

Figure 243: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

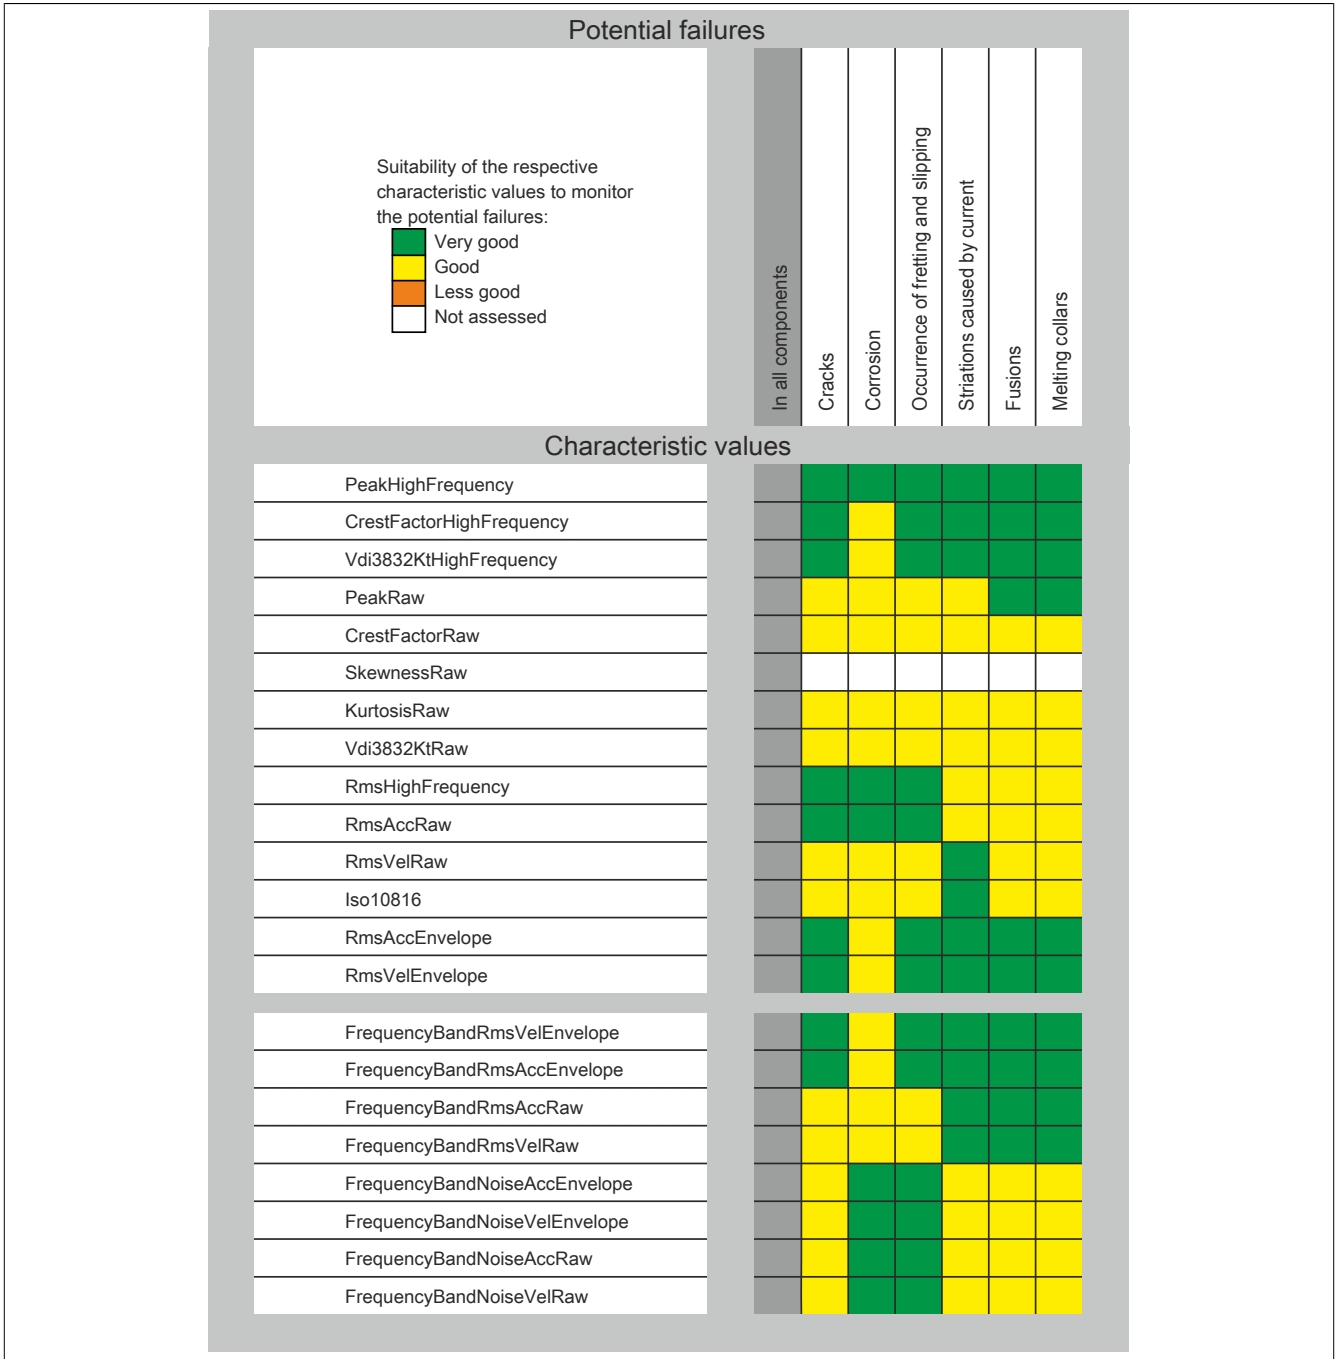

Figure 244: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Typical outer and inner ring damage

Outer ring damage

In most cases the outer ring remains stationary while the inner ring turns. This gives a clearly defined fixed load zone. Most damage occurs in this load zone. If pitting or other surface damage forms, vibrations occur when the roller element moves over it that can be measured on the housing components.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|-------------------|----------------------------------|--------------------------------|--|
| Outer ring damage | (1 x fa) | 1 x fa, 2 x fa, 3 x fa ... | With advanced damage, the outer ring frequencies can also be seen in the raw signal spectrum |

fa ... Frequency of the outer ring damage

Inner ring damage

Any inner ring damage that occurs travels with the rotating shaft. Due to the different rotary speeds of the revolving roller elements and the inner ring, pronounced modulations occur. As a result, inner ring damage frequencies are usually shown with sidebands in the spectrum.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|-------------------|----------------------------------|--------------------------------|--|
| Inner ring damage | (1 x fi) | i x fi ± i x fn | Inner ring damage generally appears based on modulation with pronounced sidebands for the speed. |

fi ... Frequency of the inner ring damage

fn ... Nominal speed

Calculating damage frequencies

Details of bearing damage frequencies are normally provided by the manufacturer and can be taken from the data sheets for the bearings.

However, they can also be calculated easily. The following values are necessary for this.

| | |
|-----------|-----------------------------|
| N | Speed in rpm |
| n_b | Number of roller elements |
| d | Diameter of roller elements |
| β_c | Pressure angle |
| D | Roller ring diameter |

Formula for calculating the inner ring damage frequency

$$f_i = \frac{n_b \cdot N}{2 \cdot 60} \cdot \left[1 + \frac{d}{D} \cdot \cos \beta_c \right]$$

Figure 245: Calculation of the inner ring damage frequency

fi ... Inner ring damage frequency

Formula for calculating the outer ring damage frequency

$$f_a = \frac{n_b \cdot N}{2 \cdot 60} \cdot \left[1 - \frac{d}{D} \cdot \cos \beta_c \right]$$

Figure 246: Calculation of the outer ring damage frequency

fa ... Outer ring damage frequency

Formula for calculating the roller element damage frequency

Damage impacting the individual pitch line:

$$f_{ew} = \frac{1}{2} \cdot \frac{D \cdot N}{d \cdot 60} \cdot \left[1 - \left(\frac{d}{D} \cdot \cos \beta_c \right)^2 \right]$$

Figure 247: Calculating the damage frequency on one roller element

few ... Damage frequency of the individual roller element

Damage impacting both pitch lines:

$$f_w = \frac{D \cdot N}{d \cdot 60} \cdot \left[1 - \left(\frac{d}{D} \cdot \cos \beta_c \right)^2 \right]$$

Figure 248: Calculating the damage frequency on both roller elements

fw ... Damage frequency of both roller elements

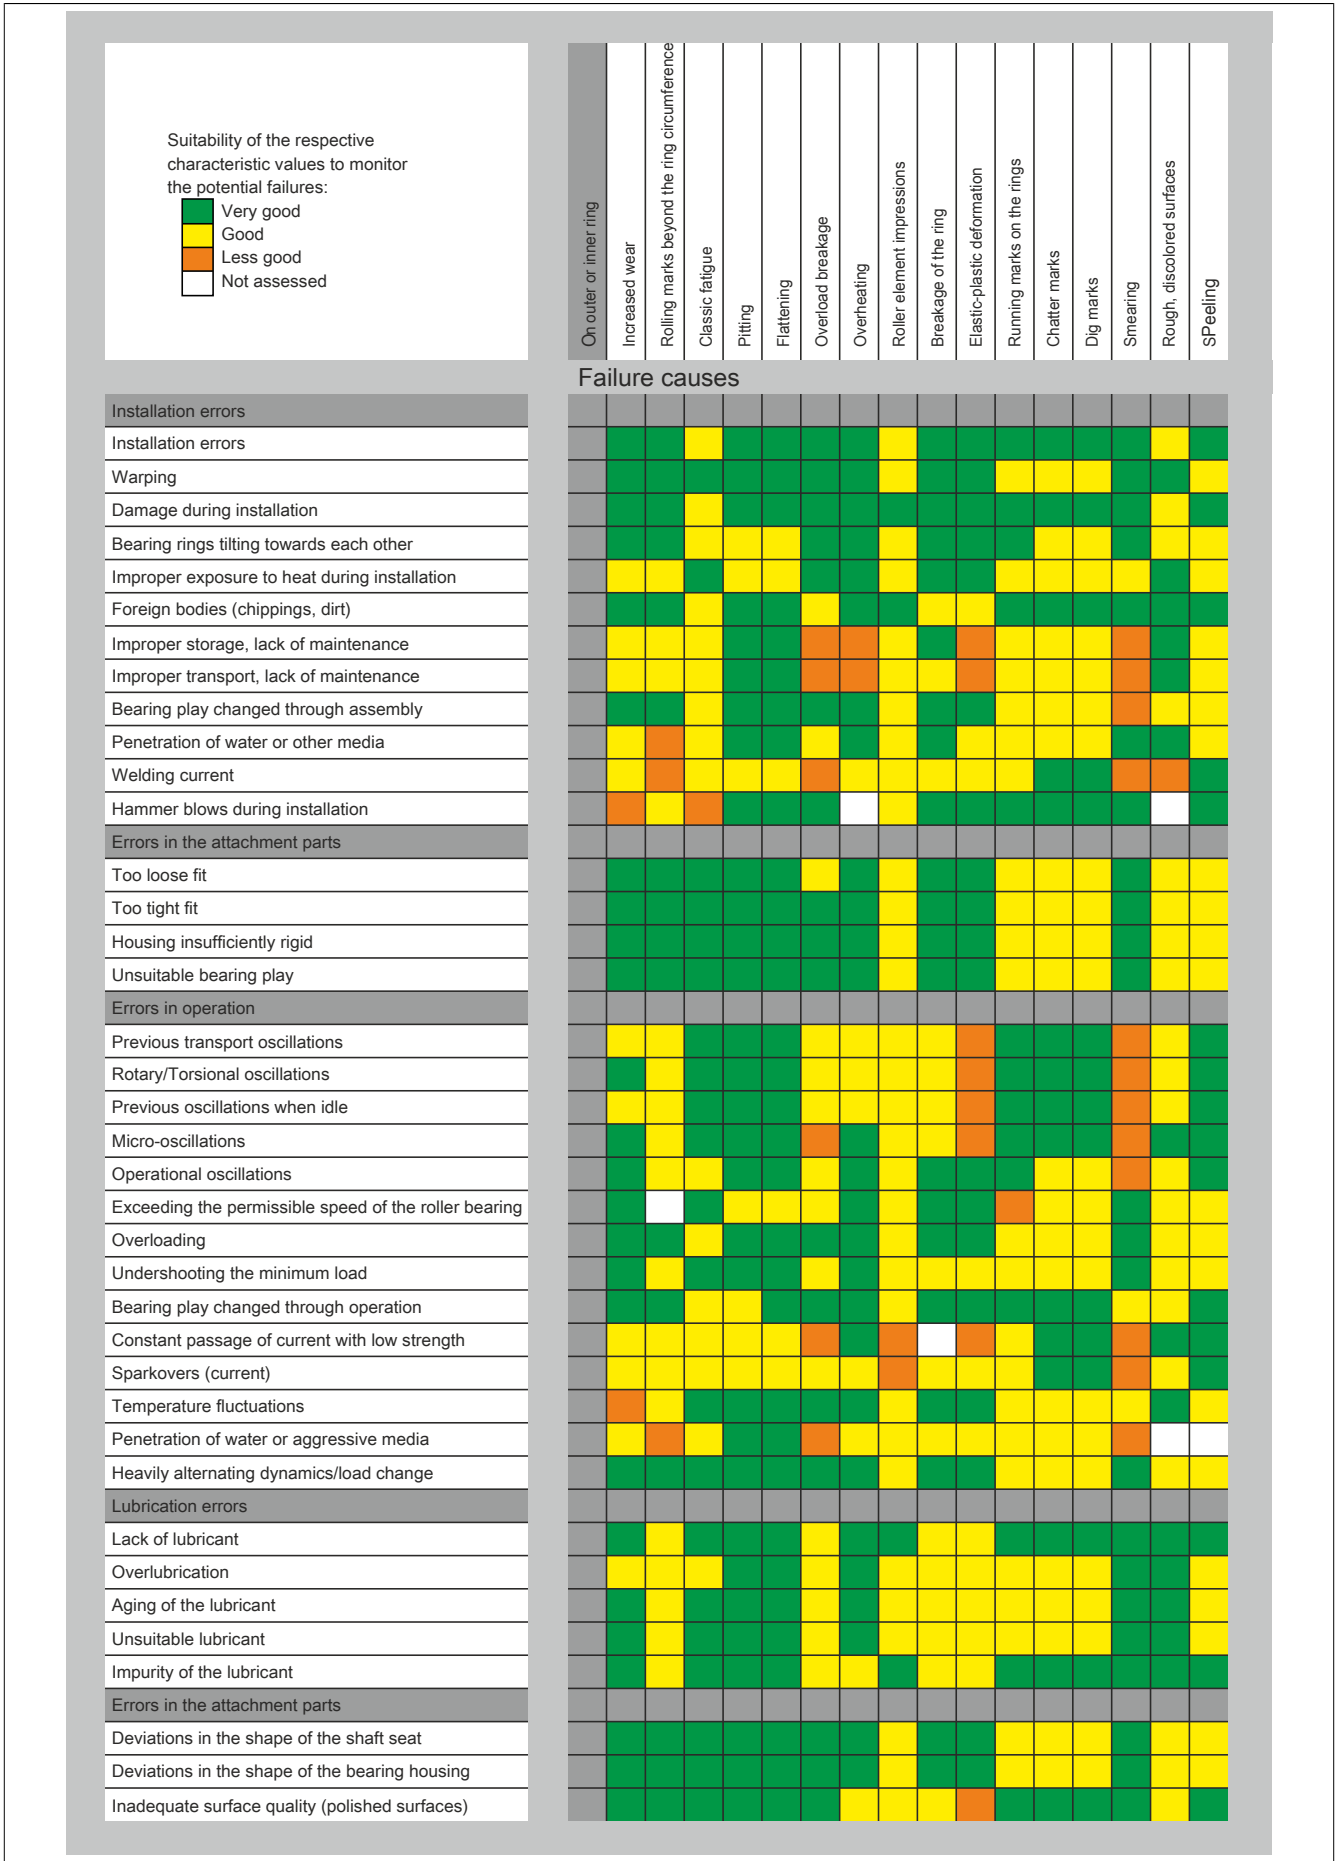

Figure 249: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

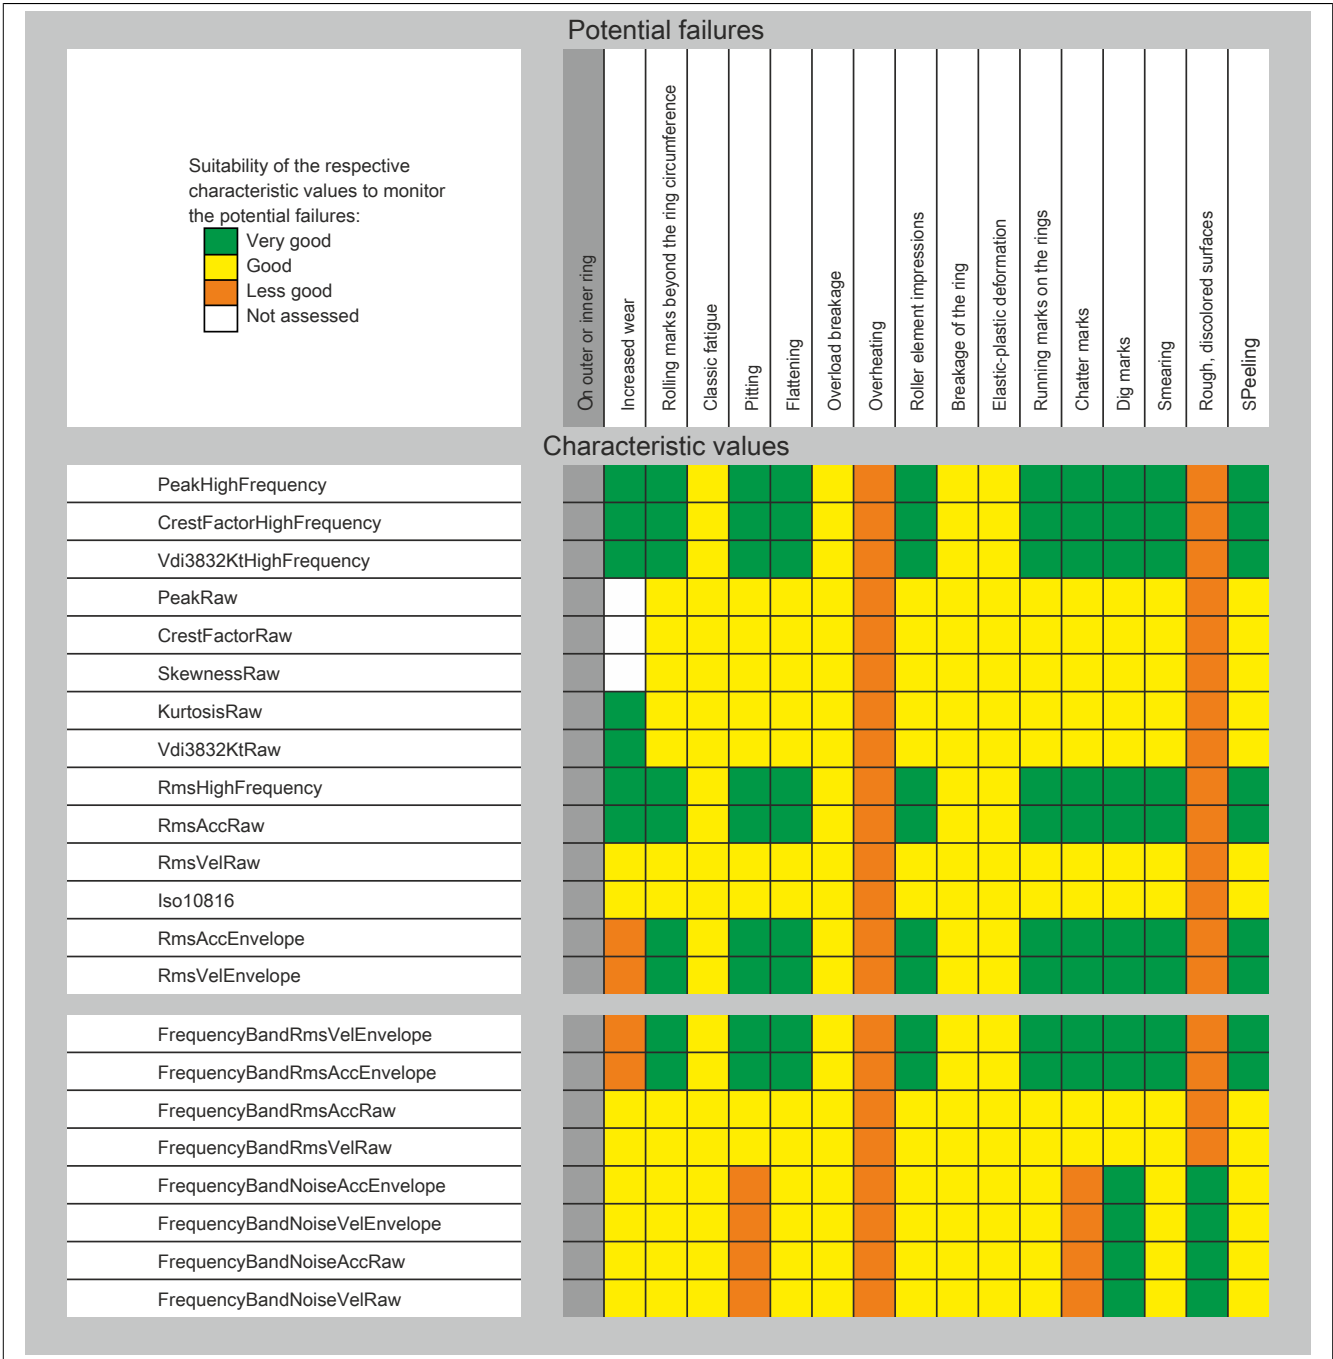

Figure 250: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Typical cage and roller element damage

Cage damage

Cage frequencies often occur in electric motors, especially where bearings with increased bearing play are used. If this is not used, oscillation of the cage often occurs. This is then reflected in increased operating noise.

Roller element damage

Damage to rolling elements without damage to the outer or inner ring occurs extremely rarely; the individual features are therefore only given as examples.

If the roller element is damaged, an impact occurs either on the inner ring, outer ring or both. This makes it possible to detect damage to rolling elements caused by the rollover frequency or twice the frequency. For this reason, the harmonic should be included in the characteristic value calculation where possible to detect roller element damage.

For the damage symptoms, see "Typical outer and inner ring damage" on page 3142.

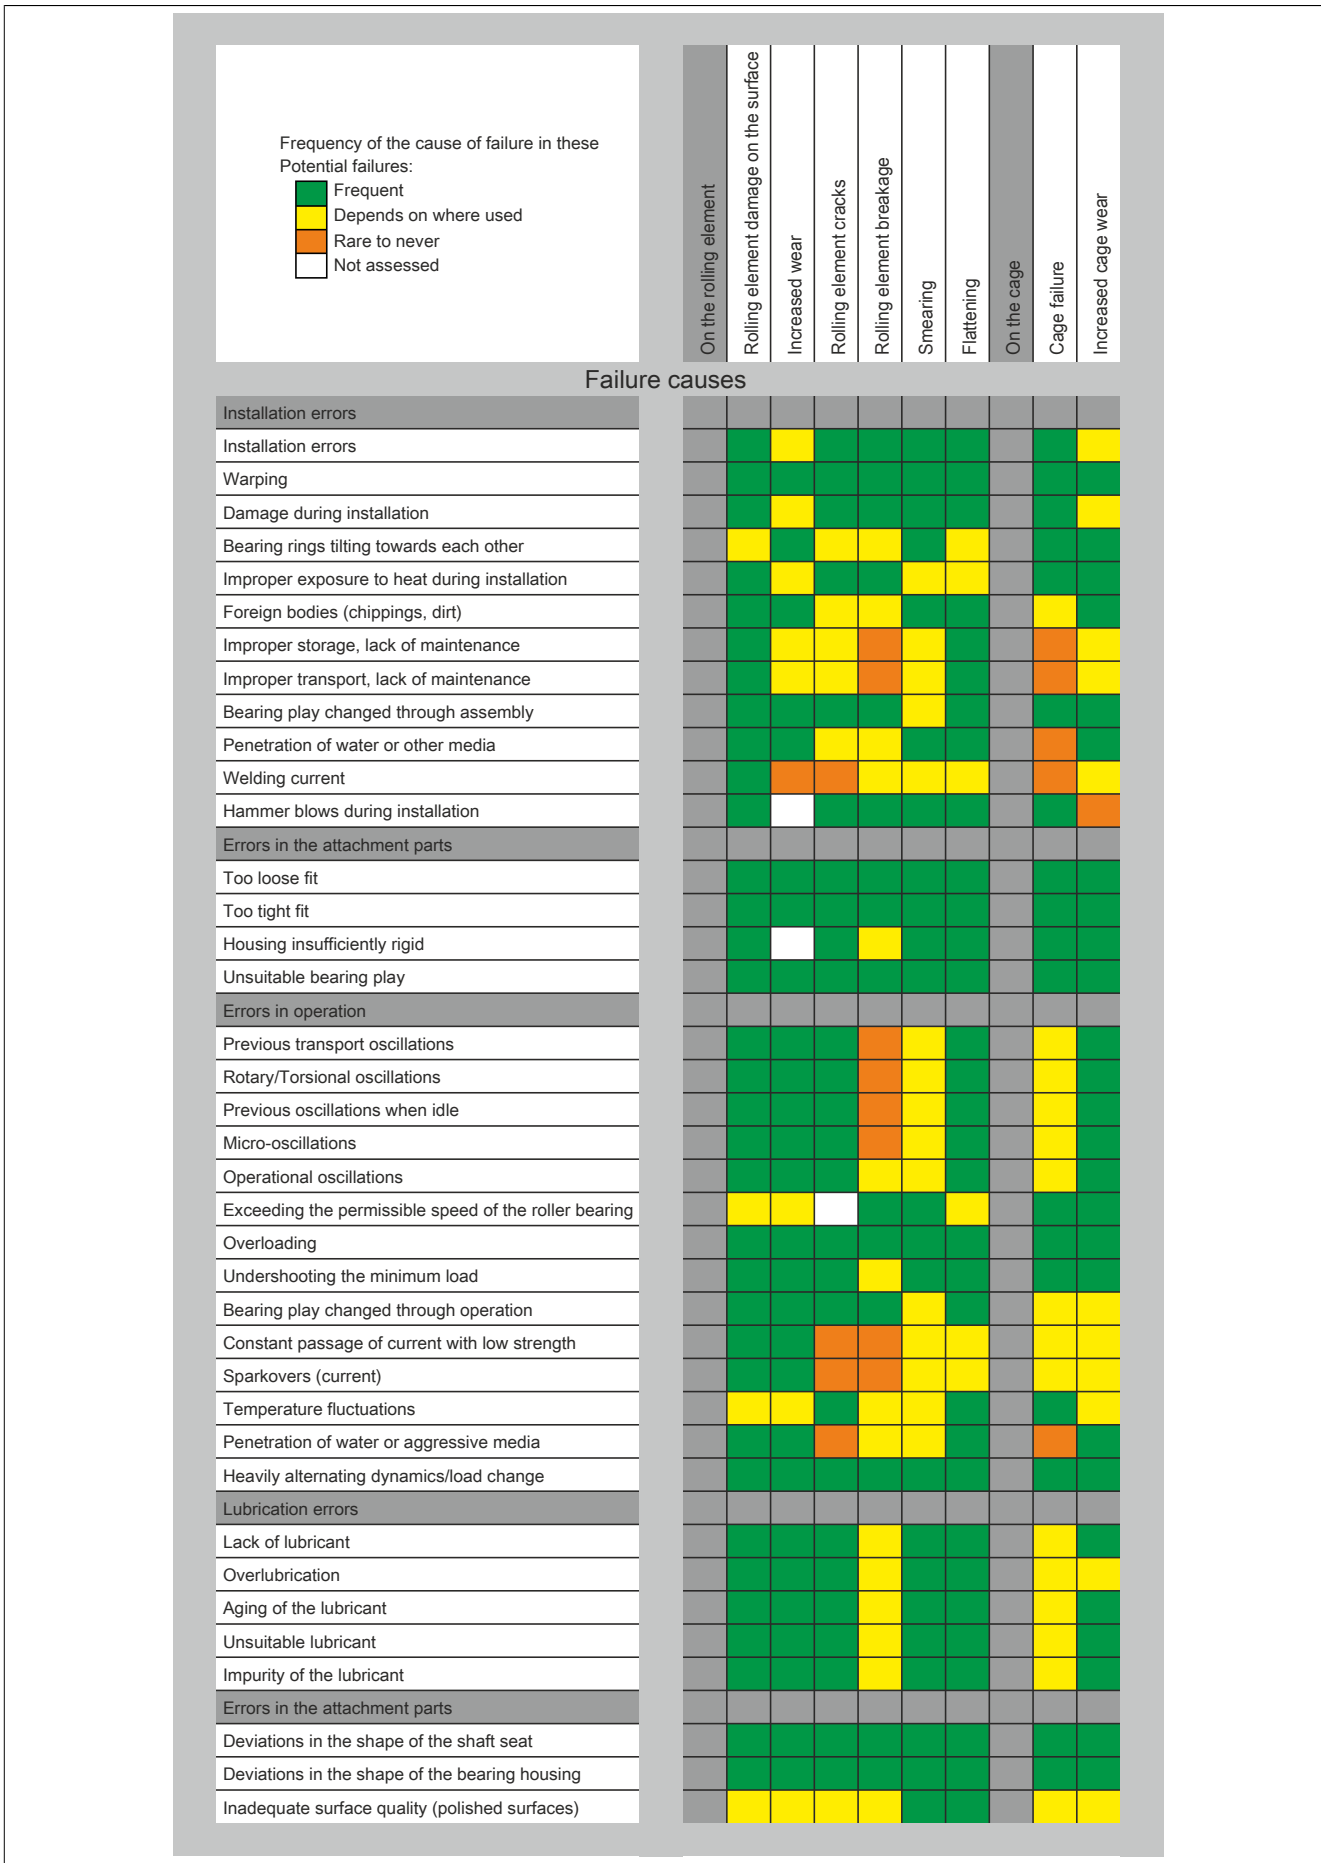

Figure 251: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

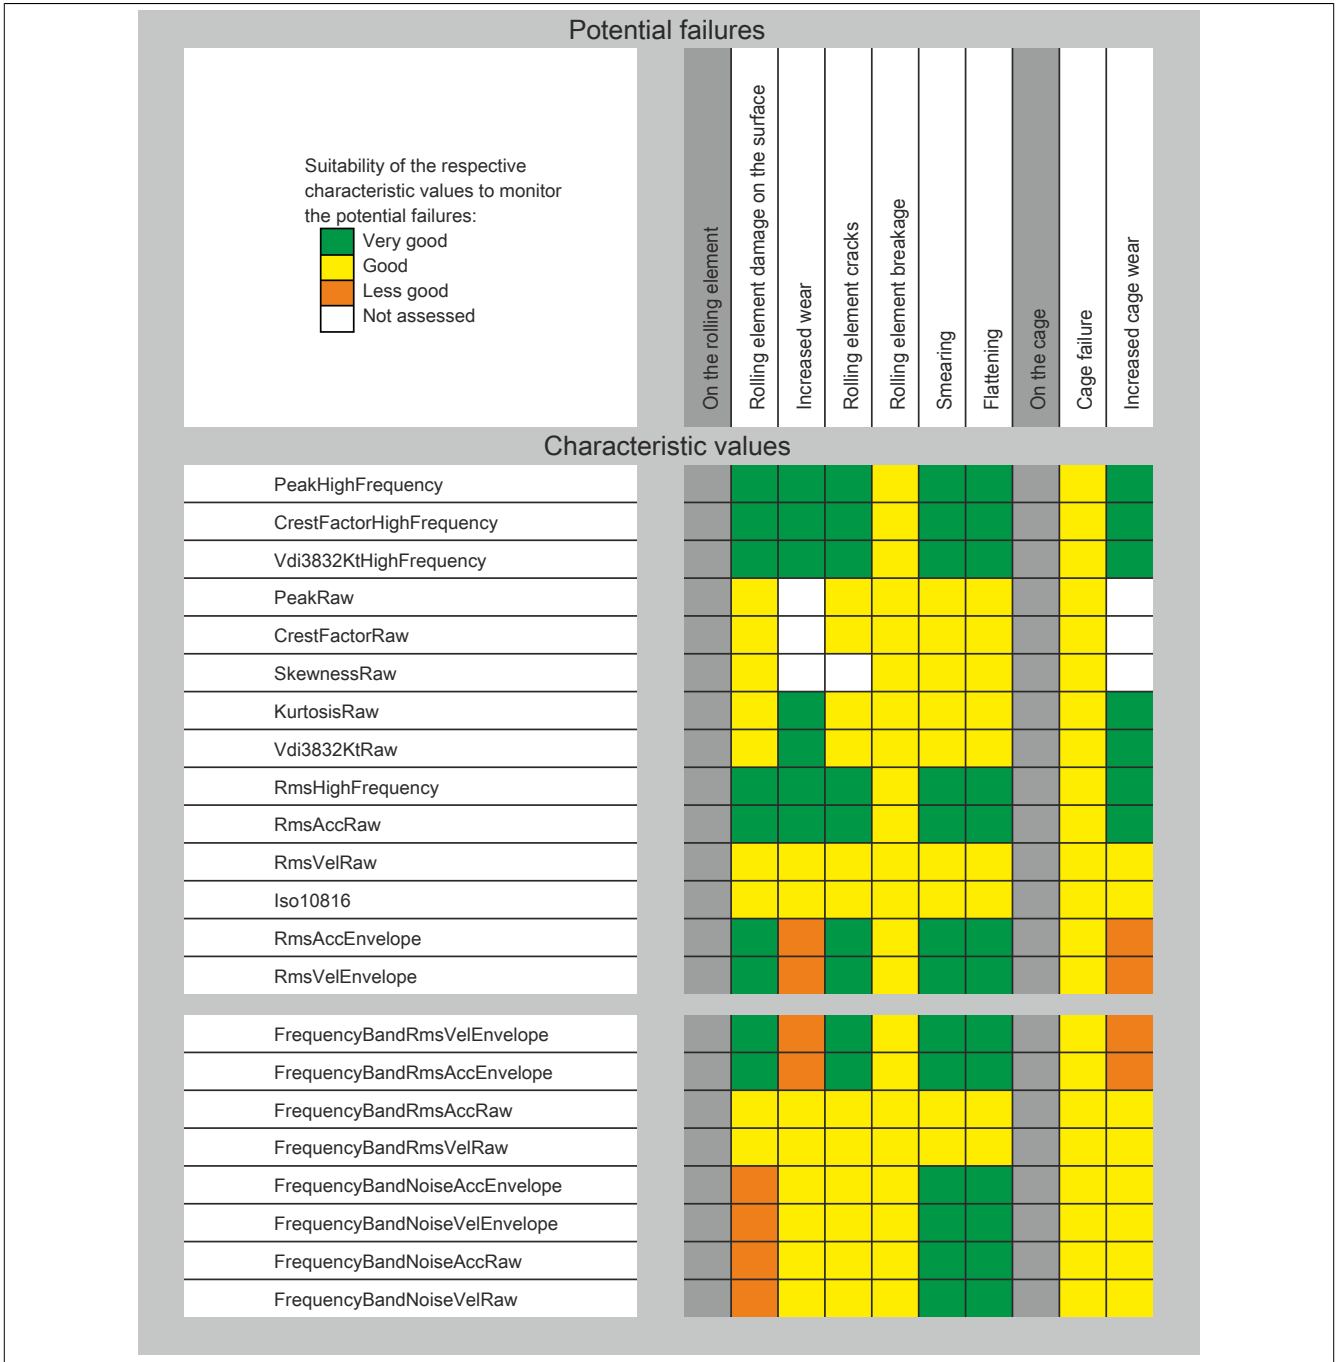

Figure 252: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Gear damage

DIN 3979 provides a description of gear errors and defects. The most common errors in individual gearboxes are described below.

The complexity of the machine dynamics must be taken into consideration in individual applications.

Gear ratio

The speed ratio must always be converted according to the gear ratio. The frequencies on the gearwheels are always based on the speed of the respective axis.

Manufacturing defects

Oscillations due to manufacturing always occur in a gearbox. Typical manufacturing defects are pitch errors, profile deviations, concentricity and spacing errors.

Depending on the gearwheel pairing, these individual defects can intensify or become less intense depending on how the defects affect each other. The interplay of the individual defects is also responsible for the overall oscillation behavior.

Pitch error is a frequently occurring defect and is used as an example here. Depending on whether the pitch error is positive or negative, it is intensified or compensated by an existing load. The effects on the oscillation behavior depend very much on the rigidity of the gearwheel. If there is a pitch error, a shock occurs that can be measured effectively.

In addition to pitch errors, all form and dimensional gear errors lead to oscillations.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|---------------------|----------------------------------|--------------------------------|---|
| Meshing frequencies | $1 \times fz$ | $1 \times fz$ | Gear frequencies depend on the respective geometric ratios of the wheels but can be precisely calculated in any case. |

fz ... Meshing frequency

Defects caused by wear

If form and dimensional deviations occur during operation, observing the trend can lead to an appropriate level of confidence when performing diagnostics.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|---------------|----------------------------------|--------------------------------|---|
| Deterioration | $1 \times fz$ | $1 \times fz \pm i \times fn$ | Geometric errors increasingly appear additionally with sidebands for the tooth meshing frequency. |

fz ... Meshing frequency

fn ... Nominal speed

Wobbling

If the toothed belt axis and the rotation axis are not parallel, the phenomenon called wobbling occurs. This causes 2 flank errors per revolution. Depending on the position, there is one transmission on the inner edge and one on the outer edge of the toothed wheel.

The doubled speed frequency is clearly evident in the frequency spectrum.

| Failure mode | Frequency in raw signal spectrum | Frequency in envelope spectrum | Comment |
|--------------|----------------------------------|--------------------------------|--|
| Wobbling | $1 \times fn, 2 \times fn$ | $1 \times fz, 2 \times fz$ | Wobbling movements manifest as doubled speed frequency and are usually accompanied by sidebands. |

fn ... Nominal speed

fz ... Meshing frequency

Cyclic running errors and axial distance errors

In DIN 3960, axial distance errors are defined as a deviation between the target/actual value.

An error that changes the distance between two axes changes the way the gears mesh and has a negative effect on the overlap ratio.

Even small pitch errors lead to increased noise in the gearbox.

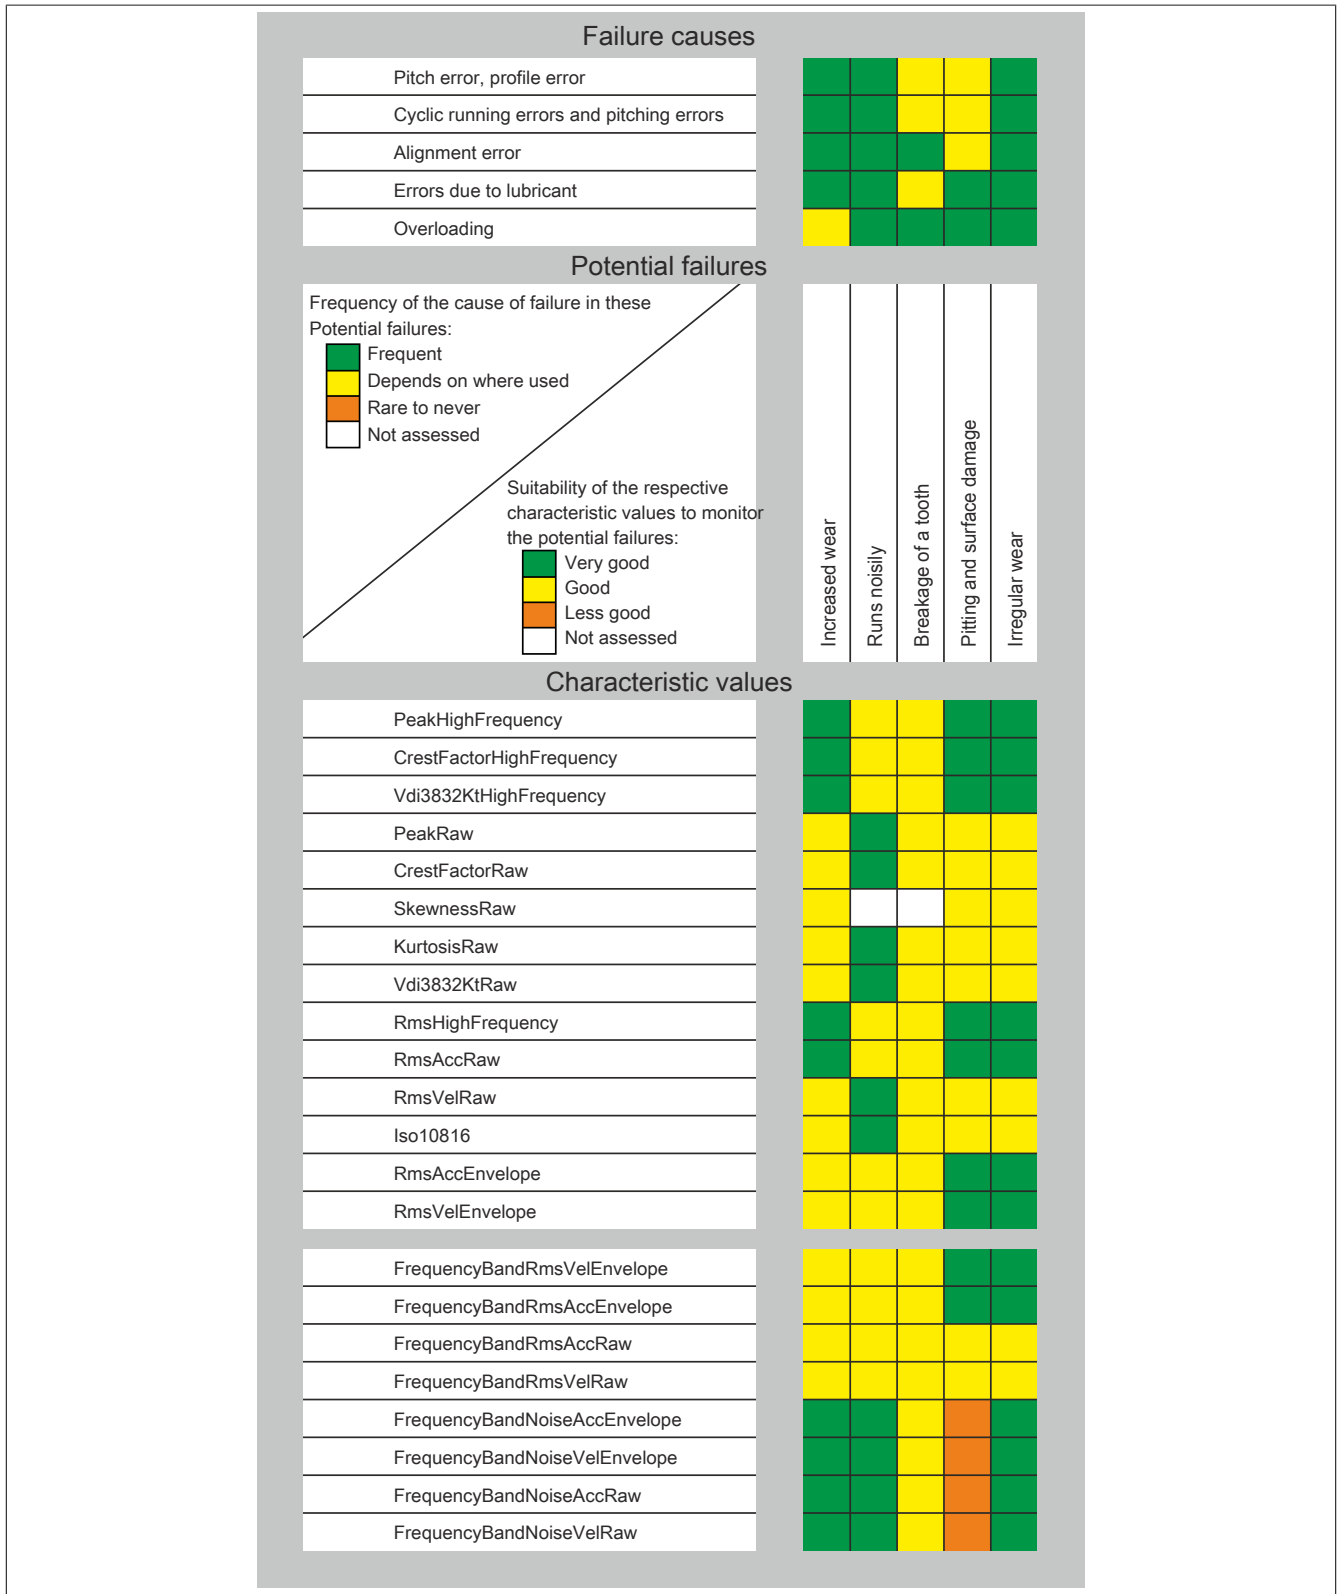

Figure 253: Frequency of failure indicators for gearbox damage

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

Electrical errors

Occasionally, bridges in the rotor bars or short circuit rings occur. They occur as a result of overloading as well as aging and the ongoing oscillation load. This leads to a very uneven distribution of the induction current in the rotor.

| Failure causes | | | | |
|------------------------|--------|-------|--------|--------|
| Overloading | Green | Green | Green | Yellow |

Figure 266: Structure of a gearbox with countershaft

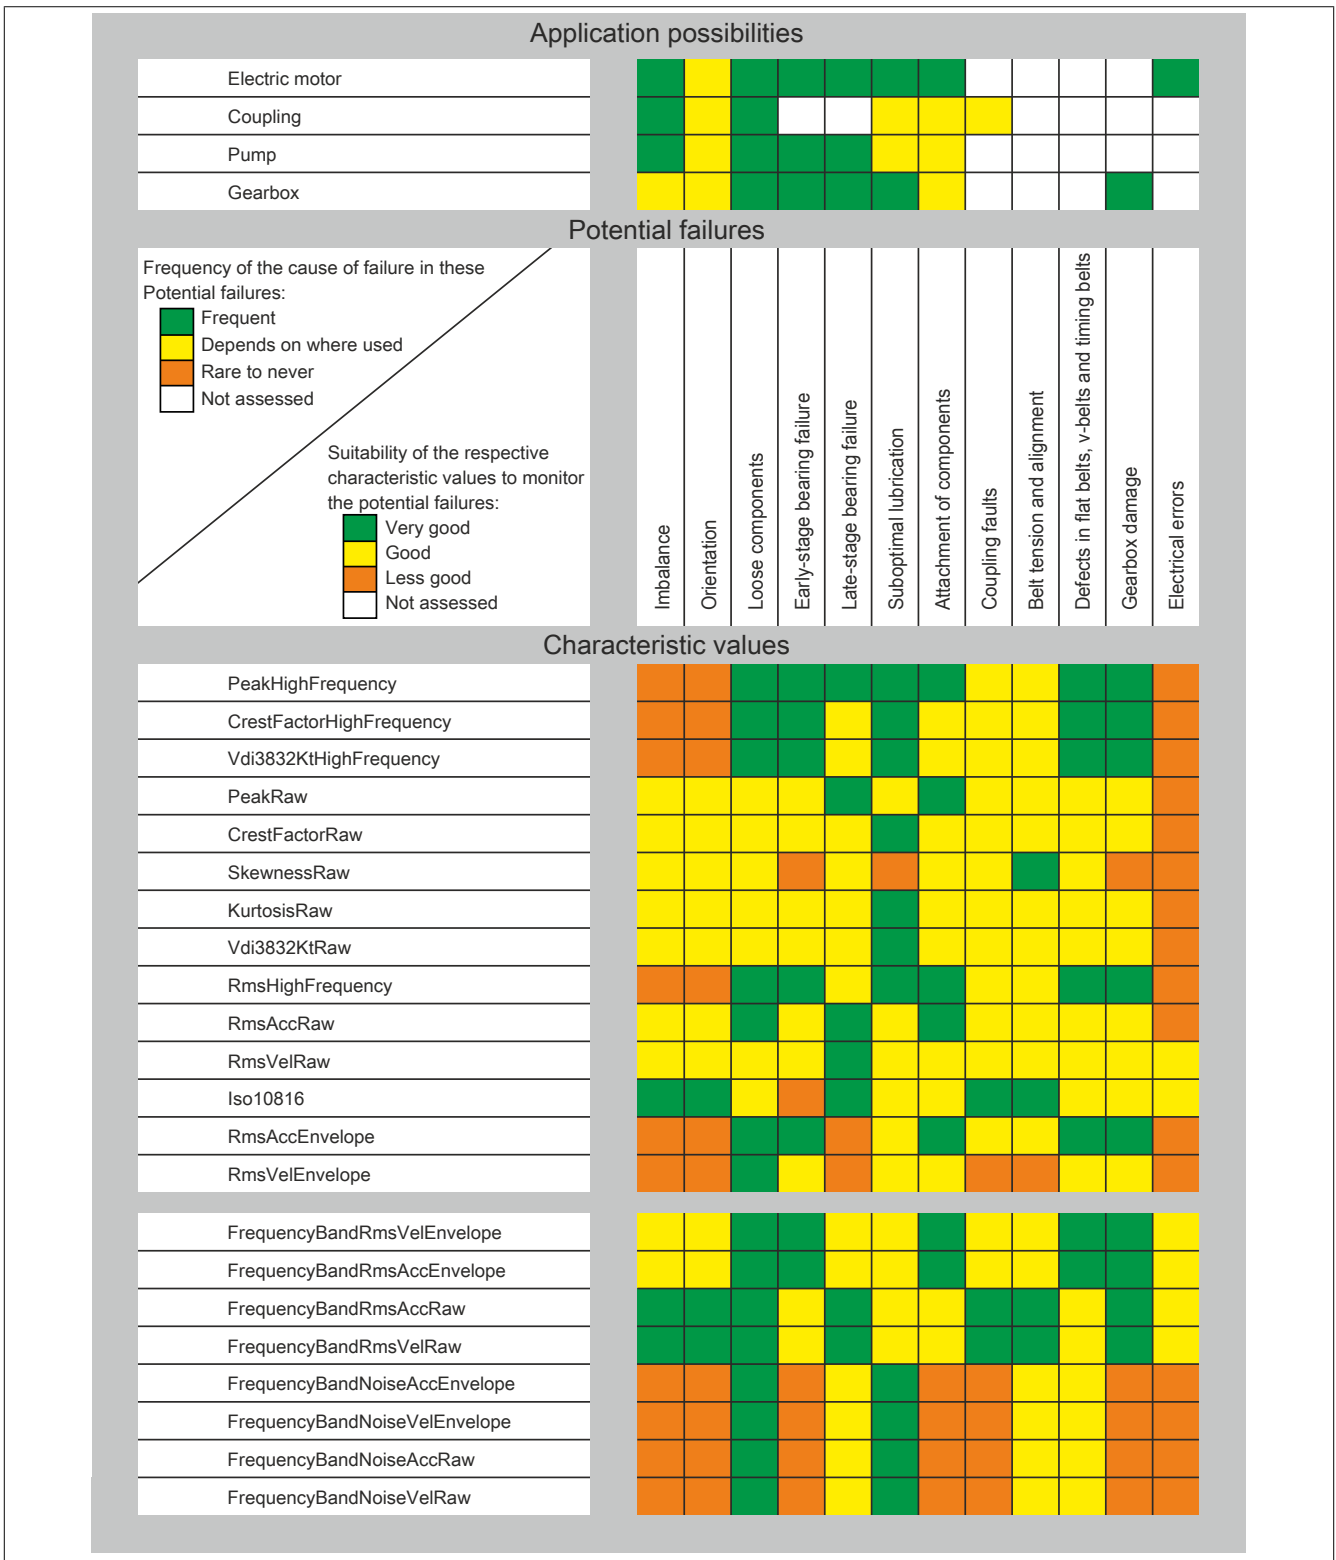

Condition monitoring solution

Figure 267: System diagram - Gearbox with countershaft

Sensor usage:

| | |
|---------------------|---|
| Number of sensors | Usually 5 sensors. 2 sensors are sufficient for smaller and inflexibly coupled drive units. |
| Sensor installation | Preferably vertical. Horizontal installation is also possible, if necessary. |

Gearbox with countershaft - Common problems:

For the meaning of individual characteristic values, see "Characteristic values" on page 3070 and "Configuration" on page 3093.

9.26.7.16.4 Further reading

Due to its extensive nature, the subject of oscillation analysis can only be outlined in this user's manual.

The following book is well suited to beginners and recommended for those wishing to research this subject in greater detail.

Zustandsüberwachung von Maschinen [Condition Monitoring of Machines]

Publisher: Expert-Verlag GmbH
Author: Dr. Josef Kolerus and Prof. Dr. Johann Wassermann
Edition: 5th, newly revised 2011 edition
Language: German
Pages: 408
ISBN-13: 978-3-8169-3080-8

9.26.7.17.2.4 Cable diagram

9.26.8 X20CM6209

Data sheet version: 2.24

9.26.8.1 General information

This module is a diode array module with six diodes. The diodes can be used as freewheeling diodes or decoupling diodes.

The diode array module has no connection to X2X Link. It behaves like a dummy module.

- 6 potential-free diodes
- 24 VDC
- 1 A current load for each diode

9.26.8.2 Order data

| Model number | Short description | Figure |
|--------------|---|--|

The following diagram illustrates the permitted summation current depending on the ambient temperature.

9.26.9 X20CM8281

Data sheet version: 3.15

9.26.9.1 General information

The module is a universal mixed module. On this module, digital I/O and analog I/O are combined. A current or voltage signal can be used for the analog I/O as desired. Counter functions on two of the digital inputs expand the range of use.

- Digital and analog channels
- Selectable current and voltage for AI and AO
- Counter functions

9.26.9.2 Order data

| Model number | Short description | Figure |
|--------------|---|--|
| | Other functions |  |
| X20CM8281 | X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ± 10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ± 10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement | |

Table 551: X20CM8281 - Technical data

- 1) Based on the current measured value.
- 2) Based on the 20 V measurement range.
- 3) Based on the 20 mA measurement range.
- 4) Based on the current output value.
- 5) Based on the entire output range.
- 6) Based on the output range.

9.26.9.4 LED status indicators

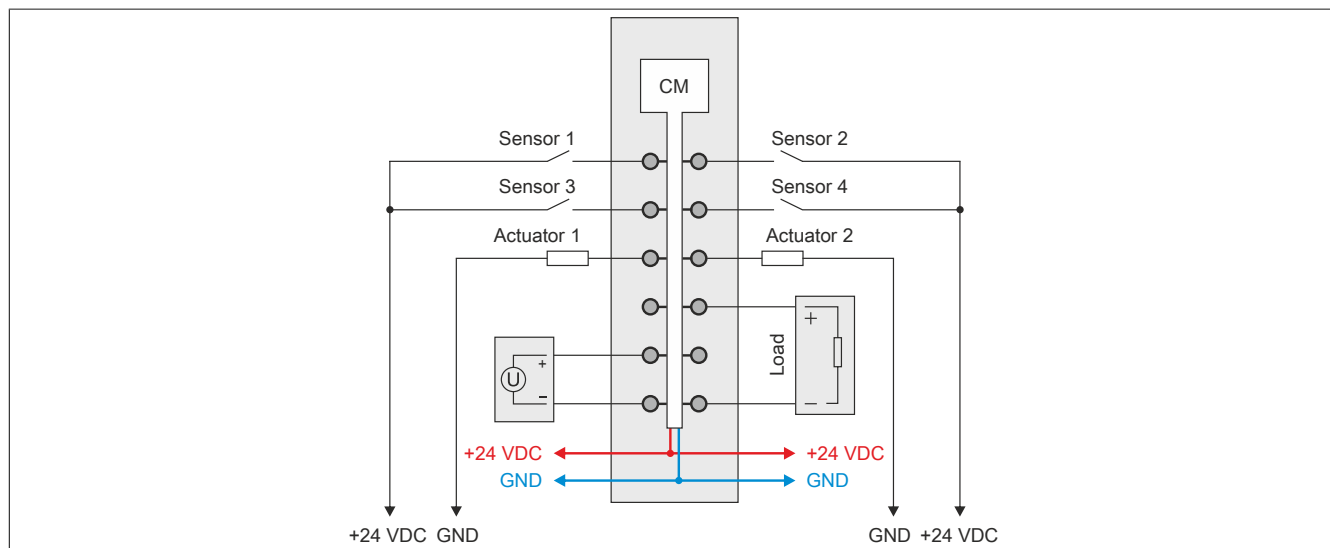

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-----------------------------|--------------|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered. |
| | e + r | Red on / Green single flash | | Invalid firmware |
| | 1 - 4 | Green | | Input state of the corresponding digital input |
| | 1 - 2 | Orange | | Output status of the corresponding digital output |
| | 1 | Green | Off | Open line or sensor is disconnected |
| | | | Blinking | Input signal overflow or underflow |
| | | | On | Analog/digital converter running, value OK |
| | 1 | Orange | Off | Value = 0 |
| | | | On | Value ≠ 0 |

9.26.9.10 Derating

There is no derating when operated below 55°C.

During operation over 55°C, the power dissipation of the modules to the left and right of this module is not permitted to exceed 1.15 W!

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

9.26.9.11 Register description

9.26.9.11.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.26.9.11.2 Function model 0 - Standard

| Register | Name | Data type | Read | | Write | |

1) The offset specifies the position of the register within the CAN object.

9.26.9.11.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.9.11.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.26.9.11.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 μ s with a network-related jitter of up to 50 μ s.

9.26.9.11.4.1 Digital inputs and status of the digital outputs

Name:

DigitalInput01 to DigitalInput04

StatusDigitalOutput01 to StatusDigitalOutput02

This register is used to indicate the input state of the digital inputs and the status of the digital outputs.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------------|--------|---|
| 0 | DigitalInput01 | 0 or 1 | Input state - Digital input 1 |
| ... | | ... | |
| 3 | DigitalInput04 | 0 or 1 | Input state - Digital input 1 |
| 4 | StatusDigitalOutput01 | 0 | Digital output channel 1: No error |
| | | 1 | Digital output channel 1: Short circuit or overload |
| 5 | StatusDigitalOutput02 | 0 | Digital output channel 2: No error |
| | | 1 | Digital output channel 2: Short circuit or overload |
| 6 - 7 | Reserved | - | |

9.26.9.11.4.2 Digital input filter

Name:

ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 μ s. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 μ s.

| Data type | Value | Filter |
|-----------|-------|---|
| USINT | 0 | No software filter (bus controller default setting) |
| | 2 | 0.2 ms |
| | ... | ... |
| | 250 | 25 ms - Higher values are limited to this value |

9.26.9.11.4.3 Event or gate counter

Event counter operation

The rising (positive) edges are registered on the counter input.

The counter status is collected with a fixed offset to the network cycle and transferred in the same cycle.

Gate measurement

The time of rising to falling edges for the gate input is registered using an internal frequency. The result is checked for overflow (0xFFFF) and corrected with the adjustable prescaler.

The recovery time between measurements must be >100 μ s.

The measurement result is transferred with the falling edge to the result memory.

Event or gate counter

Name:

Counter01 to Counter02

Counter01 is intended for event counter operation.

Event counter operation or gate measurement can be selected for Counter02:

| Data type | Value |
|-----------|---------------|
| UINT | Counter value |

Counter configuration

Name:

ConfigOutput02

This register can be used to configure and reset the individual counters.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Name | Value | Information |
|-------|---|-------|--|
| 0 - 3 | Counter02 (counter frequency, only with gate measurement) | 0 | 48 MHz (bus controller default setting) |
| | | 1 | 3 MHz |
| | | 2 | 187.5 kHz |
| | | 3 | 24 MHz |
| | | 4 | 12 MHz |
| | | 5 | 6 MHz |
| | | 6 | 1.5 MHz |
| | | 7 | 750 kHz |
| | | 8 | 375 kHz |
| 4 | ResetCounter01 | 0 | No influence on the counter |
| | | 1 | Clear counter (at positive edge) |
| 5 | ResetCounter02 | 0 | No influence on the counter |
| | | 1 | Clear counter (at positive edge) |
| 6 - 7 | Counter02 (operating mode) | 0 | Event counter measurement (bus controller default setting) |
| | | 1 | Gate measurement |

This register also includes configuration data in addition to the cyclic data. If the register is used cyclically and in the init script, then the preset configuration only remains available when operated directly on the CPU. On the bus controller, the configuration is always overwritten with 0.

However, starting with upgrade version 1.0.2.1, the cyclic bit can be hidden in order to prevent the configuration from being overwritten.

Information:

If the counter should be cleared, this must be done using a non-cyclic write command. When doing so, the configuration bit must be transferred together with the reset counter bit!

9.26.9.11.4.4 Rising edge input latch

Using this function, the rising edges of the input signal can be latched with a resolution of 200 μ s. With the "Acknowledge - input latch" function, the input latch is either reset or prevented from latching.

It works in the same way as a dominant reset RS flip-flop.

Input state of digital latch inputs 1 - 4

Name:

DigitalInputLatch01 to DigitalInputLatch04

This register is used to indicate input state of digital inputs 1 to 4 after expiration of the input filter time.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|---------------------|--------|---|
| 0 | DigitalInputLatch01 | 0 or 1 | Input state of digital input 1 after expiration of the delay time |
| ... | | ... | |
| 3 | DigitalInputLatch04 | 0 or 1 | Input state of digital input 4 after expiration of the delay time |
| 4 - 7 | Reserved | - | |

Acknowledge digital inputs

Name:

DigitalInput01LatchQuitt to DigitalInput04LatchQuitt

This register is used to reset the input latches channel by channel.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|--------------------------|-------|----------------------------------|
| 0 | DigitalInput01LatchQuitt | 0 | No influence on the latch status |
| | | 1 | Resets the latch status |
| ... | | ... | |
| 3 | DigitalInput04LatchQuitt | 0 | No influence on the latch status |
| | | 1 | Resets the latch status |
| 4 - 7 | Reserved | - | |

9.26.9.11.5 Digital outputsThe output state is transferred to the output channels with a fixed offset (<60 μ s) based on the network cycle (SyncOut).**9.26.9.11.5.1 Switching state of digital outputs 1 to 2**

Name:

DigitalOutput01 to DigitalOutput02

This register is used to store the switching state of digital outputs 1 to 2.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|-----------------|-------|-------------------------|
| 0 | DigitalOutput01 | 0 | Digital output 01 reset |
| | | 1 | Digital output 01 set |
| 1 | DigitalOutput02 | 0 | Digital output 02 reset |
| | | 1 | Digital output 02 set |

9.26.9.11.5.2 Digital inputs and status of the digital outputs

Name:

DigitalInput01 to DigitalInput04

StatusDigitalOutput01 to StatusDigitalOutput02

This register is used to indicate the input state of the digital inputs and the status of the digital outputs.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------------|--------|---|
| 0 | DigitalInput01 | 0 or 1 | Input state - Digital input 1 |
| ... | | ... | |
| 3 | DigitalInput04 | 0 or 1 | Input state - Digital input 1 |
| 4 | StatusDigitalOutput01 | 0 | Digital output channel 1: No error |
| | | 1 | Digital output channel 1: Short circuit or overload |
| 5 | StatusDigitalOutput02 | 0 | Digital output channel 2: No error |
| | | 1 | Digital output channel 2: Short circuit or overload |
| 6 - 7 | Reserved | - | |

9.26.9.11.6 Analog inputs

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

9.26.9.11.6.1 Analog input register

Name:

AnalogInput01

This register is used to indicate the analog input value depending on the configured operating mode.

| Data type | Value | Input signal: |
|-----------|-----------------|------------------------------|
| INT | -32768 to 32767 | Voltage signal -10 to 10 VDC |
| | 0 to 32767 | Current signal 0 to 20 mA |
| | 0 to 32767 | Current signal 4 mA to 20 mA |

9.26.9.11.6.2 Input filter

This module is equipped with a configurable input filter. The minimum cycle time must be $>400\ \mu\text{s}$. Filtering is disabled for shorter cycle times.

If the input filter is active, then the channels are scanned in 1 ms cycles. Conversion is performed acyclically to the X2X cycle.

Information:

The filter sampling time is fixed at 1 ms and is acyclic to the X2X cycle.

Input ramp limiting

Input ramp limiting can only be performed in conjunction with filtering. Input ramp limiting is performed before filtering.

The difference of the input value change is checked for exceeding the specified limit. In the event of overshoot, the tracked input value is equal to the old value \pm the limit value.

Configurable limit values:

| Value | Limit value |
|-------|---|
| 0 | The input value is used without limitation. |
| 1 | 0x3FFF = 16383 |
| 2 | 0x1FFF = 8191 |
| 3 | 0x0FFF = 4095 |
| 4 | 0x07FF = 2047 |
| 5 | 0x03FF = 1023 |
| 6 | 0x01FF = 511 |
| 7 | 0x00FF = 255 |

Input ramp limiting is well suited for suppressing disturbances (spikes). The following examples show the functionality of input ramp limiting based on an input step and a disturbance.

Example 1

The input value jumps from 8000 to 17000. The diagram shows the tracked input value with the following settings:

Input ramp limiting = 4 = 0x07FF = 2047

Filter level = 2

Figure 270: Tracked input value for input step

Example 2

A disturbance interferes with the input value. The diagram shows the tracked input value with the following settings:

Input ramp limiting = 4 = 0x07FF = 2047

Filter level = 2

Figure 271: Tracked input value for disturbance

Filter level

A filter can be defined to prevent large input steps. This filter is used to bring the input value closer to the actual analog value over a period of several milliseconds.

Filtering takes place after any input ramp limiting has been carried out.

Formula for calculating the input value:

$$\text{Value}_{\text{New}} = \text{Value}_{\text{Old}} - \frac{\text{Value}_{\text{Old}}}{\text{Filter level}} + \frac{\text{Input value}}{\text{Filter level}}$$

Adjustable filter levels:

| Value | Filter level |
|-------|---------------------|
| 0 | Filter switched off |
| 1 | Filter level 2 |
| 2 | Filter level 4 |
| 3 | Filter level 8 |
| 4 | Filter level 16 |
| 5 | Filter level 32 |
| 6 | Filter level 64 |
| 7 | Filter level 128 |

The following examples show the functionality of the filter based on an input step and a disturbance.

Example 1

The input value jumps from 8000 to 16000. The diagram shows the calculated value with the following settings:

Input ramp limiting = 0

Filter level = 2 or 4

Figure 272: Calculated value during input step

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limiting = 0

Filter level = 2 or 4

Figure 273: Calculated value during disturbance

9.26.9.11.6.3 Configuring the input filter

Name:

ConfigOutput03

This register is used to define the filter level and input ramp limitation of the input filter.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------------|-------|--|
| 0 - 2 | Defines the filter level | 000 | Filter disabled (bus controller default setting) |
| | | 001 | Filter level 2 |
| | | 010 | Filter level 4 |
| | | 011 | Filter level 8 |
| | | 100 | Filter level 16 |
| | | 101 | Filter level 32 |
| | | 110 | Filter level 64 |
| | | 111 | Filter level 128 |
| 3 | Reserved | 0 | |
| 4 - 6 | Defines input ramp limiting | 000 | The input value is applied without limitation (bus controller default setting) |
| | | 001 | Limit value = 0x3FFF (16383) |
| | | 010 | Limit value = 0x1FFF (8191) |
| | | 011 | Limit value = 0x0FFF (4095) |
| | | 100 | Limit value = 0x07FF (2047) |
| | | 101 | Limit value = 0x03FF (1023) |
| | | 110 | Limit value = 0x01FF (511) |
| | | 111 | Limit value = 0x00FF (255) |
| 7 | Reserved | 0 | |

9.26.9.11.6.4 Lower limit for the analog value

Name:

ConfigOutput05

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

| Data type | Values | Information |
|-----------|-----------------|--|
| INT | -32768 to 32767 | Bus controller default setting: -32768 |

Information:

- The default value of -32768 corresponds to the minimum default value of -10 VDC.
- For current measurements, this value should be set to 0.
- When configured as 4 to 20 mA, this value can be set to -8192 (corresponds to 0 mA) in order to display values <4 mA.

9.26.9.11.6.5 Upper limit for the analog value

Name:

ConfigOutput06

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

| Data type | Values | Information |
|-----------|-----------------|---------------------------------------|
| INT | -32767 to 32767 | Bus controller default setting: 32767 |

Information:

- The default value of 32767 corresponds to the maximum default value of 20 mA or +10 VDC.

9.26.9.11.6.6 Status of the analog input

Name:
StatusInput01

This register is used to monitor the analog input on the module. A change in the monitoring status generates an error message.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|----------------------------|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Lower limit value exceeded |
| | | 10 | Upper limit value exceeded |
| | | 11 | Open line ¹⁾ |
| 2 - 7 | Reserved | 0 | |

1) Open-circuit detection does not occur during current signal measurement.

9.26.9.11.7 Analog output

The channel can be configured for either current or voltage signals. The type of signal is also determined by the terminals used.

9.26.9.11.7.1 Analog output register

Name:
AnalogOutput01

This register is used to output the analog output value appears depending on the operating mode that is set.

| Data type | Value | Information |
|-----------|-----------------|------------------------------|
| INT | -32768 to 32767 | Voltage signal -10 to 10 VDC |
| | 0 to 32767 | Current signal 0 to 20 mA |

9.26.9.11.8 Configuration of the analog inputs and outputs

Name:
ConfigOutput04

This register can be used to define the type and range of signal measurement.

Each channel is capable of handling either current or voltage signals. The type of signal is determined by the terminal connections used. Since current and voltage require different adjustment values, it is also necessary to configure the desired type of output signal.

Input signal:

- ± 10 V voltage signal
- 0 to 20 mA current signal
- 4 to 20 mA current signal

Output signal:

- ± 10 V voltage signal
- 0 to 20 mA current signal

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------|-------|--|
| 0 - 1 | Analog input | 00 | Voltage signal -10 VDC to +10 VDC (bus controller default setting) |
| | | 01 | Current signal 0 mA to 20 mA |
| | | 11 | Current signal 4 mA to 20 mA |
| 2 - 3 | Reserved | 0 | |
| 4 | Analog output | 0 | Voltage signal -10 VDC to +10 VDC (bus controller default setting) |
| | | 1 | Current signal 0 mA to 20 mA |
| 5 - 7 | Reserved | 0 | |

9.26.9.11.9 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|--------------------|--------|
| Without filtering | 100 µs |
| With filtering | 150 µs |

9.26.9.11.10 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|---------------------------|---------|
| Digital without filtering | 150 µs |
| Digital with filtering | 200 µs |
| Analog without filtering | 400 µs |
| Analog with filtering | 1000 µs |

9.26.10 X20CM8323

Data sheet version: 3.15

9.26.10.1 General information

The module has digital outputs for switching electromechanical loads (e.g. valves, relays) and additional functions.

- 8 digital outputs
- Current trace
- Switching time detection
- Pulse width modulation

9.26.10.2 Order data

| Model number | Short description | Figure |
|--------------|--|--|
| | Other functions |  |
| X20CM8323 | X20 PWM module, 8 digital outputs for switching electro-mechanical loads, 0.6 A continuous current, 2 A peak current, current monitoring, switching time detection | |
| | Required accessories | |
| | Bus modules | |

- 1) Rev. G0 and higher: Up to a maximum of 6 channels only are permitted to be switched on simultaneously over 55°C.
- 2) Rev. G0 and higher: Up to a maximum of 6 channels only are permitted to be switched on simultaneously over 45°C.

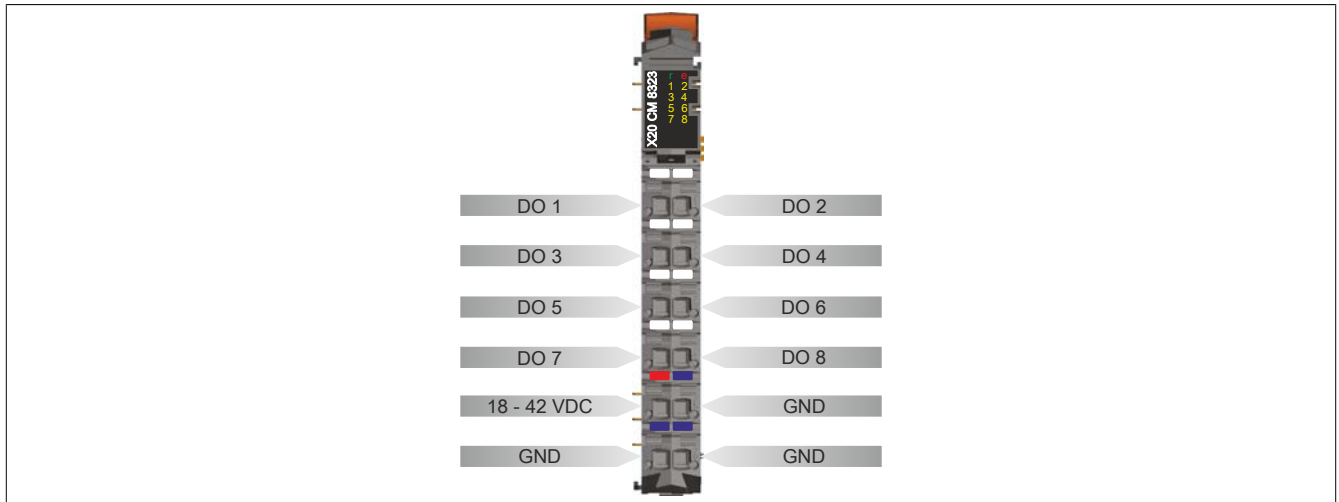

9.26.10.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

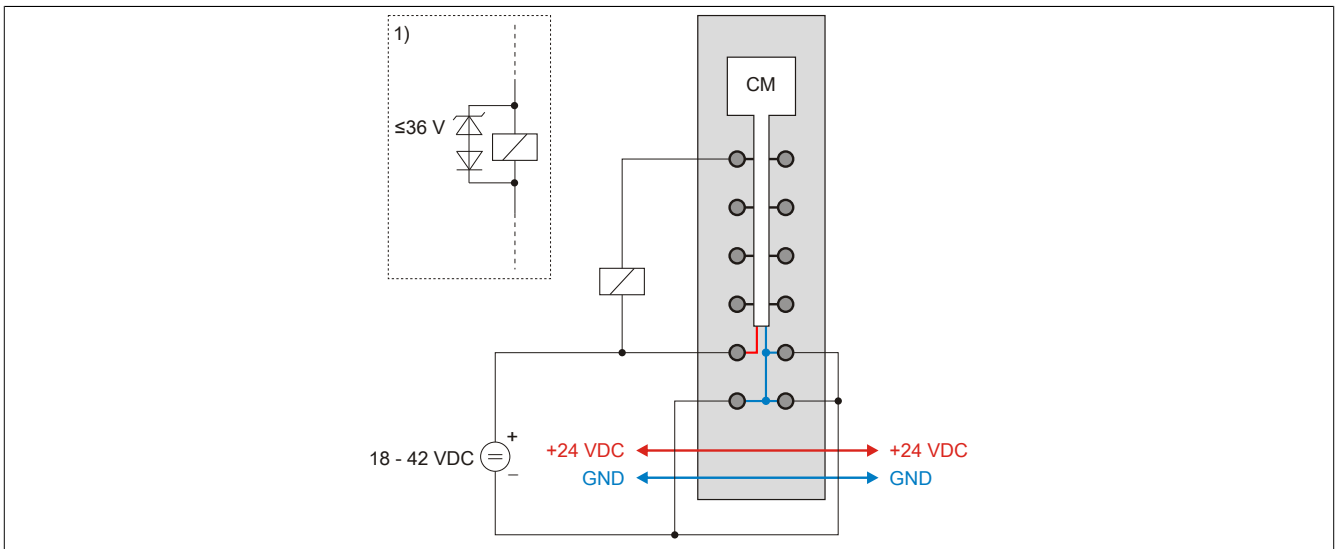

| Figure | LED | Color | Status | Description |
|--------|-------|--------|-----------------------------|--|
| | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered. |
| | e + r | | Red on / Green single flash | Invalid firmware |
| | 1 - 8 | Orange | On/Off | Status of the digital outputs |
| | | | Blinking | Short-circuit / overcurrent cutoff |
| | | | | <p>Information:</p> <p>The output is not automatically activated after an overcurrent cutoff. It must be switched on again.</p> |

- 1) Depending on the configuration, a firmware update can take up to several minutes.

9.26.10.5 Pinout

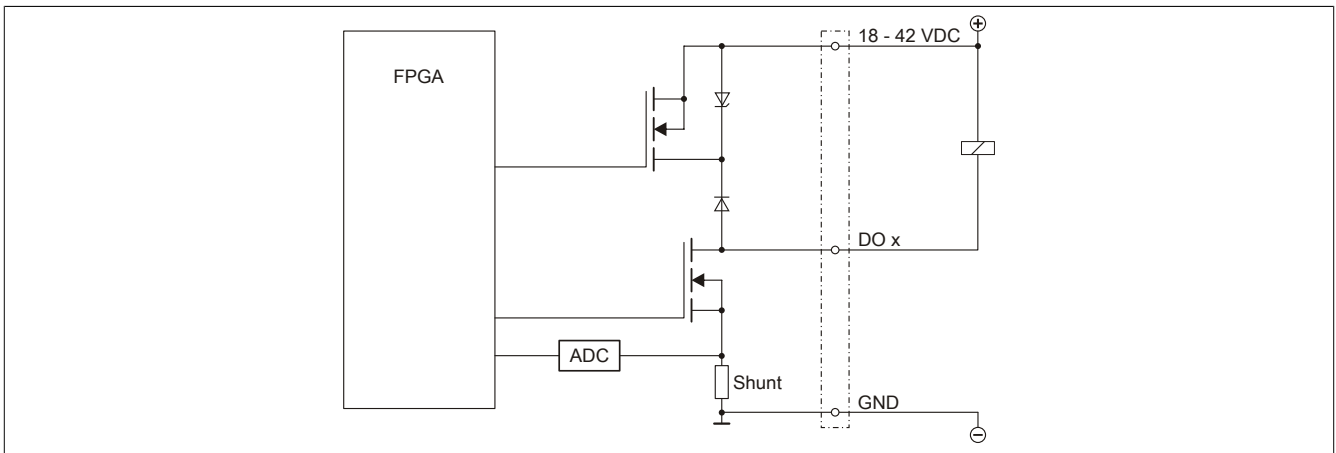

9.26.10.6 Connection example

1) If larger inductances or more current are used; the "transil-diode combination" must be placed externally on the relay/valve.

9.26.10.7 Output circuit diagram

9.26.10.8 Switching inductive loads

Prior to revision G0

From revision G0

In principle, the inductance that is connected is limited by the maximum power dissipation of the module.

If larger inductances or more current are used, the the "transil-diode combination" must be placed externally on the relay/valve (see ["Connection example" on page 3200](#)).

Information:

The inductance of a relay/valve depends greatly on the core material being used. Therefore, an inductance must be used that corresponds to the diagram at 1Hz. This information can be found in the data sheet of the connected inductance (relay/valve).

9.26.10.9 Register description

9.26.10.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.26.10.9.2 Function model 0 - Standard

| Register | Name | Data type | Read | | Write | |
|----------------------|--|-----------|--------|------------|--------|------------|
| | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| Configuration | | | | | | |

| 0 | 0 | IndexAct | UINT | • | | | |
| | 0 | LineID_Act | USINT | | | | |
| | 1 | BlockID_Act | USINT | | | | |

1) The offset specifies the position of the register within the CAN object.

9.26.10.9.4.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.10.9.4.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.26.10.9.5 Configuration registers

9.26.10.9.5.1 Excitation time

Name:

ConfigOutput02

The excitation time is configured in this register.

The output is switched fully on for the time set in this register after the module is switched on. After the excitation time expires, the module goes into PWM mode.

| Data type | Value | Information |
|-----------|----------|---|
| USINT | 0 to 255 | In steps of 100 µs or 1000 µs. Bus controller default setting: 0 |

9.26.10.9.5.2 PWM duty cycle

Name:

ConfigOutput03

In this register, a configuration is made for the percentage of the PWM cycle (in 1% steps) that the PWM output is logical 1, i.e. ON.

| Data type | Value | Information |
|-----------|---------|---|
| USINT | 0 | PWM output always off |
| | 1 to 99 | Switch-on time in 1% steps. Bus controller default setting: 50 |
| | 100 | PWM output always on |

9.26.10.9.5.3 Module configuration

Name:

ConfigOutput04

This register is used to configure the module's general parameters.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|-------|---|
| 0 | PWM frequency | 0 | 1 kHz (bus controller default setting) |
| | | 1 | 50 kHz |
| 1 | Reserved | | |
| 2 | Excitation time base | 0 | 100 μ s (bus controller default setting) |
| | | 1 | 1000 μ s |
| 3 | Reserved | | |
| 4 | Switching point search | 0 | Low-point method (bus controller default setting) |
| | | 1 | Curvature method |
| 5 - 7 | Reserved | | |

9.26.10.9.5.4 Current and time differential

Name:

ConfigOutput05 to ConfigOutput20

The switching point search is configured with the parameters dl and dt in these non-cyclic registers.

- dl - Current differential in LSB
- dt - Time differential in 100 μ s steps

For a sample configuration, see ["Configuring dl and dt" on page 3212](#)

| Data type | Values | Information |
|-----------|----------|-----------------------------------|
| USINT | 0 to 255 | Bus controller default setting: 0 |

| Registers | Description | |
|----------------|-------------|-----------|
| ConfigOutput05 | dl | Channel 1 |
| ConfigOutput06 | dt | |
| ... | | ... |
| ConfigOutput19 | dl | Channel 8 |
| ConfigOutput20 | dt | |

9.26.10.9.5.5 Disabling the high-speed cutoff

Name:

ConfigOutput21

The high-speed cutoff can be enabled or disabled for individual channels in this register.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-----|-------------------|-------|--|
| 0 | High-speed cutoff | 0 | Enabled for channel 1 (bus controller default setting) |
| | | 1 | Disabled for channel 1 |
| ... | | ... | |
| 7 | High-speed cutoff | 0 | Enabled for channel 8 (bus controller default setting) |
| | | 1 | Disabled for channel 8 |

9.26.10.9.5.6 Configuration of the time base

Name:

TimeBase

This register can be used to configure the interval between current measurement points.

The interval between measurement points is normally one quarter of the defined X2X Link cycle. When using a CAN controller this value is not available. The time base for the 1/4 measurement cycle must therefore be set separately in [Function model 254 - Bus controller](#).

| Data type | Value | Information |
|-----------|--------------|--|
| UINT | 400 to 10000 | Measurement point interval in μ s for 1/4 measurement cycle. Bus controller default setting: X2X cycle time |

9.26.10.9.6 Communication registers

9.26.10.9.6.1 Uploading the current curves (function models 0 and 1)

A current curve with 200 values is recorded for each channel. The interval between measurement points is equal to a quarter of the defined X2X Link cycle.

The following registers are used to read the current curve recorded by the module:

- "AnalogInput01" on page 3205
- "AnalogInput02 to Analog09" on page 3205

Set the channel number and line index

Name:

AnalogInput01

If this register contains a valid value (i.e. index is in the valid range) then registers "AnalogInput02 to AnalogInput09" on page 3205 provide a block of 8 current values for Channel X.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------|---------|-------------|
| 0 - 2 | Channel number | 0 | Channel 1 |
| | | ... | |
| | | 7 | Channel 8 |
| 3 - 7 | Index | 0 to 24 | Line index |

The index specifies which part of the current curve is represented by the block of 8 values:

| Value X of the current curve | Index | Register |
|------------------------------|-------|---------------|
| 1 | 0 | AnalogInput02 |
| 2 | | AnalogInput03 |
| ... | | ... |
| 8 | | AnalogInput09 |
| 9 | 1 | AnalogInput02 |
| ... | | ... |
| 193 | | AnalogInput02 |
| ... | | ... |
| 200 | 24 | AnalogInput09 |

Table 554: Relationship between index, channel and AnalogInput02 - AnalogInput09

Examples

The 200th value of the curve contains the switching point of the connected valve/relay found by the module.

- Value 200 = 78: The 78th measurement point corresponds to the switching point of the valve/relay.
- Value 200 = 255: No switching point was found.

Analog input values

Name:

AnalogInput02 to AnalogInput09

A current curve with 200 values is recorded for each channel. These registers provide a block of 8 current values from Channel X.

The following register is required for configuration:

- The "AnalogInput01" on page 3205 register defines the channel used and the block index.
- The interval between measurement points is equal to a quarter of the defined X2X Link cycle.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

Programming example in ANSI C for uploading the curves:

```

#include <bur/plctypes.h>
#define ILEN 200

typedef struct {
    USINT          data[ILEN];
} curve_typ;
typedef struct {
    BOOL          ok;
    UDINT        serial;
    UINT         id, hw, fwver;
    BOOL         out[8];
    UINT         delay;
    USINT        i_addr;
    USINT        i_ch1_in, i_ch2_in, i_ch3_in, i_ch4_in;
    USINT        i_ch5_in, i_ch6_in, i_ch7_in, i_ch8_in;
    curve_typ    curves[8];
    USINT        switched;
} cm8323_typ;
_LOCAL cm8323_typ cm;
_LOCAL USINT ventilNummer, adrPtr;

void _INIT up() {}

void _CYCLIC cycle() {
    ventilNummer = cm.i_addr & 0x07;
    adrPtr = cm.i_addr >> 3;

    if(cm.i_addr != 200 && ventilNummer <= 7) {
        cm.curves[ventilNummer].data[adrPtr * 8 + 0] = cm.i_ch1_in;
        cm.curves[ventilNummer].data[adrPtr * 8 + 1] = cm.i_ch2_in;
        cm.curves[ventilNummer].data[adrPtr * 8 + 2] = cm.i_ch3_in;
        cm.curves[ventilNummer].data[adrPtr * 8 + 3] = cm.i_ch4_in;
        cm.curves[ventilNummer].data[adrPtr * 8 + 4] = cm.i_ch5_in;
        cm.curves[ventilNummer].data[adrPtr * 8 + 5] = cm.i_ch6_in;
        cm.curves[ventilNummer].data[adrPtr * 8 + 6] = cm.i_ch7_in;
        cm.curves[ventilNummer].data[adrPtr * 8 + 7] = cm.i_ch8_in;
    }
}

```

I/O mapping of following data points for curve evaluation:

| Data point | Variable |
|---------------|-------------|
| AnalogInput01 | cm.i_addr |
| AnalogInput02 | cm.i_ch1_in |
| AnalogInput03 | cm.i_ch2_in |
| AnalogInput04 | cm.i_ch3_in |
| AnalogInput05 | cm.i_ch4_in |
| AnalogInput06 | cm.i_ch5_in |
| AnalogInput07 | cm.i_ch6_in |
| AnalogInput08 | cm.i_ch7_in |
| AnalogInput09 | cm.i_ch8_in |

9.26.10.9.6.2 Uploading the current curves with CAN I/O

A current curve with 200 values is recorded for each channel. The interval between measurement points is equal to the value set in the "TimeBase" on page 3204 register.

The following registers are needed in order to read the current curve recorded by the module in the [Function model 254 - Bus controller](#):

- "BlockID_Set" on page 3207
- "BlockID_Act" on page 3207
- "LineID_Set" on page 3207
- "LineID_Act" on page 3208
- "AnalogInput01 to AnalogInput04" on page 3208

Summary of set registers

Name:

AddressSet

This register is a summary of the "LineID_Set" on page 3207 and "BlockID_Set" on page 3207 registers.

| Data type | Bit | Information |
|-----------|--------|-------------|
| UINT | 0 - 7 | LineID_Set |
| | 8 - 15 | BlockID_Set |

Summary of read registers

Name:

IndexAct

This register is a summary of the "LineID_Act" on page 3208 and "BlockID_Act" on page 3207.

| Data type | Bit | Information |
|-----------|--------|-------------|
| UINT | 0 - 7 | LineID_Act |
| | 8 - 15 | BlockID_Act |

Sets the channel number

Name:

BlockID_Set

The channel for the data stream can be selected in this register. The value of this register can be read using "BlockID_Act" on page 3207.

| Data type | Value | Information |
|-----------|-------|-------------|
| USINT | 0 | Channel 1 |
| | ... | ... |
| | 7 | Channel 8 |

Reads the channel number

Name:

BlockID_Act

Reads the "BlockID_Set" on page 3207 register. This register allows you to determine which channel is providing the current values in registers "AnalogInput01 to AnalogInput04" on page 3208. If the selected channel or line does not exist, then this register returns the value 255.

| Data type | Value | Information |
|-----------|--------|--------------------------------------|
| USINT | 0 to 7 | Channel or line currently being used |
| | 255 | Invalid selection |

Setting the line index

Name:

LineID_Set

The line index for the data stream can be selected in this register. The value of this register can be read using "LineID_Act" on page 3208.

| Data type | Value | Information |
|-----------|---------|---------------------------|
| USINT | 0 to 49 | Line index currently used |

Reading the line index

Name:

LineID_Act

Reads the "LineID_Set" on page 3207 register. This register allows you to determine which line is providing the current values in registers "AnalogInput01 to AnalogInput04" on page 3208. If the selected channel or line does not exist, then this register returns the value 255.

If the channel number and index are in the valid range, then registers "AnalogInput01 to AnalogInput04" on page 3208 provide a block of 4 current values for Channel X.

The index specifies which part of the current curve is represented by the block of 4 values:

| Data type | Value | Information | Register |
|-----------|------------------------------|-------------|-------------------|
| USINT | Value X of the current curve | Index | |
| | 1 | 0 | AnalogInput01 |
| | ... | | ... |
| | 4 | | AnalogInput04 |
| | 5 | 1 | AnalogInput01 |
| | ... | | ... |
| | 197 | | AnalogInput01 |
| | ... | 49 | ... |
| | 200 | | AnalogInput04 |
| | 255 | | Invalid selection |

Analog input values - CAN I/O

Name:

AnalogInput01 to AnalogInput04

A current curve with 200 values is recorded for each channel. These registers provide a block of 4 current values from Channel X.

The following registers are required for configuration:

- The "BlockID_Set" on page 3207 register defines the channel used.
- The "LineID_Set" on page 3207 register defines the block index within the channel.
- The interval between measurement points is equal to the value set in the "TimeBase" on page 3204 register.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.26.10.9.6.3 Digital outputs

Name:

DigitalOutput

DigitalOutput01 to DigitalOutput08

Registers "DigitalOutput01" to "DigitalOutput08" set the output value of Channels 1 to 8.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------|--------|-----------------------------------|
| 0 | DigitalOutput01 | 0 or 1 | Output value of digital output 01 |
| ... | | ... | |
| 7 | DigitalOutput08 | 0 or 1 | Output value of digital output 08 |

9.26.10.9.6.4 Status of the outputs

Name:
StatusInput01

This register indicates whether a switching point has been found for a channel.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------|-------|--|
| 0 | Switching point | 0 | Channel 1 was not switched or no switching point was found |
| | | 1 | Switching point found for Channel 1 |
| ... | | ... | |
| 7 | Switching point | 0 | Channel 8 was not switched or no switching point was found |
| | | 1 | Switching point found for Channel 8 |

9.26.10.9.6.5 Module status

Name:
StatusInput02

The current module status is indicated in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|-------|------------------------------|
| 0 - 2 | Reserved | 0 | |
| 3 | Overload cutoff | 0 | No overcurrent |
| | | 1 | Overcurrent cutoff activated |
| 4 - 7 | Reserved | 0 | |

9.26.10.9.6.6 Switching delay of channels

Name:
StatusOutput01

2 bits of this register are used to set the switching delay for each channel. Values of the switching delay are specified in quarter-steps of the X2X Link cycle.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|------------------------------|-------|-------------------------------------|
| 0 - 1 | Switching delay of channel 1 | 00 | No delay |
| | | 01 | 1/4 of the X2X Link cycle |
| | | 10 | 2/4 of the X2X Link cycle |
| | | 11 | 3/4 of the X2X Link cycle |
| 2 - 3 | Switching delay of channel 2 | x | For possible values, see channel 1. |
| ... | | ... | |
| 14 - 15 | Switching delay of channel 8 | x | For possible values, see channel 1. |

9.26.10.9.6.7 Reads actual values of the current

Name:

Current01 to Current08

These registers are used to read the actual value of the current from channels 1 to 8. These values have no units and are used only as characteristic values. A more precise, compensated current measurement is not possible using this module.

Relationship between register name and channel number:

| Register name | Channel number |
|---------------|--|
| Current01 | Actual value of the current of Channel 1 |
| ... | ... |
| Current08 | Actual value of the current of Channel 8 |

If an output is switched off, the corresponding register returns the value 0. After the output is switched on, valid current measurements are not available on the module until after two X2X Link cycles. The measurements in the registers are delayed by two cycles to account for this.

When the output is switched on, the corresponding bit in the "[StatusCurrent](#)" on page 3210 register can be used to check whether the register contains valid measurements. The first measured value is provided with the rising edge of this bit.

| Data type | Value | Information |
|-----------|----------|------------------------|
| USINT | 0 | Output is switched off |
| | 1 to 255 | Current value |

9.26.10.9.6.8 Checking for measured values

Name:

StatusCurrent

StatusCurrent01 to StatusCurrent08

This register can be used to check whether valid measured values are present in registers "[Current01 to Current08](#)" on page 3210.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------|-------|---|
| 0 | StatusCurrent01 | 0 | Output switched off |
| | | 1 | The current value of channel 01 is valid. |
| ... | | ... | |
| 7 | StatusCurrent08 | 0 | Output switched off |
| | | 1 | The current value of channel 08 is valid. |

9.26.10.9.7 Functionality of the digital outputs

The following image shows the configuration and functionality of a digital output.

Configuration registers

- 1) Switching delay: See register "StatusOutput01" on page 3209
- 2) PWM frequency: See bit 0 of register "ConfigOutput04" on page 3204
- 3) PWM duty cycle: See register "ConfigOutput03" on page 3203
- 4) Excitation time = ConfigOutput02 * Excitation time base (bit 2 of "ConfigOutput04" on page 3204)
- 5) di / dt : See registers "ConfigOutput05 to 20" on page 3204

9.26.10.9.8 Configuring dl and dt

9.26.10.9.8.1 Procedure - Searching for switching points

Figure 274: Searching for switching points

The current in the inductance gradually rises when the valve is switched on. The valve starts to move mechanically at a certain point. This process becomes noticeable due to a current dip that occurs as a result of the braking voltage (anti-EMF) (point P1).

When this mechanical process is complete, the current returns to its original curve and continues to rise (point P2).

Point P3 and point P1 have the same current value, but different times.

A valid low-point, which simultaneously corresponds to the switching point, must meet the following criteria:

- Point 2 must be lower than P1 by dI
- The time between P1 and P3 must be longer than dt

9.26.10.9.8.2 Configuration example for dl and dt with trace data from Automation Studio

Figure 275: Search for the switching point with trace data from Automation Studio

The difference between the "current high-point" ($P1 = 131$) and the subsequent low-point ($P2 = 58$) is calculated ($P1 - P2 = 73$). The module compares this difference to the configured parameter dI .

If the difference measured by the module is larger than the configured dI value, then the first condition for a switching point search is met:

- In the module, the parameter dI should therefore be set to at least 72.

The next criteria is the time between P1 and P3. This must be larger than the value set for the parameter dt .

According to the trace data, this is 4.43 ms:

- In the module, the parameter dt should therefore be set to 43 ($4430 \mu s / 100 \mu s$).

With that, the second condition is met and a valid switching point can be detected.

It is recommended to avoid setting values all the way to the limits, since valves and relays change mechanically over time, which can lead to faulty readings (unless you wish to detect every minor deviation from the reference curve).

9.26.10.9.8.3 Modified switching point search (curvature method)

The method described (searching for and detecting switching points by locating low-points in the current trace) may not provide the desired level of reliability for certain types of valves and under certain conditions (e.g. pneumatic pressure).

For this reason, an alternative method of switchover detection is provided. This method is based on an evaluation of the curvature of the current curve. In the module configuration, the user can select which method to use for switchover detection (see "[Module configuration](#)" on page 3204).

The modified switching point search calculates the first derivative (slope) and then the second derivative (curvature) for every point in the current curve. At the switching point this second derivative has a local maximum, which is found by the module. More specifically, in order to improve the signal/noise ratio, a summation window is moved over the second derivative and the maximum of this summation is searched for.

This is not only valid when the current trace itself has a more or less low minimum in the switching point, but also in cases where the current increase only levels-out in the area of the switching point, but never becomes negative. Therefore, it can be said that the curvature method should generally be more sensitive.

Like the switching point search with the low-point method, valid switching points are configured using the parameters dl and dt. The meaning of these parameters is different here, however.

- dl - minimum curvature sum
- dt - width of the summation window in 1/4 X2X Link cycles

Meaningful values for this parameter can no longer be obtained simply by reading / measuring the current trace. That is why the module provides, in addition to the switching point (200th value of the current curve), also the following measurement and calculation values that can be used for the configuration:

| Value X of the current curve | Description |
|------------------------------|---|
| 1 | 1. Value of the current curve |
| : | : |
| 197 | Peak position of the first valid or highest invalid curvature peak |
| 198 | Height of the peak sum of the first valid or highest invalid peak |
| 199 | Width of the first valid or highest invalid peak (Important: not standardized to 100 μ s) |
| 200 | 255 at invalid peak, otherwise peak position in the current trace |

When a valid maximum curvature has been found (Value 198 \geq dl) then Values 197 to 199 represent the position (= Value 200), height and width of the first maximum that meets the criteria. Any higher and/or wider maximum that occurs later will not be found!

If no maximum curvature reaches the necessary height, then Values 197 through 200 represent the highest invalid maximum.

Determining the parameters dl and dt

| | |
|------------------------|--|
| dl \ll Value 198 | Set dl much lower than 198 |
| dt \approx Value 199 | dt should be set approximately the same as Value 199 Note: Maximum value for dt = 16 |

A certain amount of jitter in Value 198 must be assumed due to the high sensitivity of the modified switching point search. It is therefore recommended to monitor Value 198 over several switching cycles before setting dl with a safety clearance from the lowest monitored value.

As you can see in the examples below, the switching point peak is a number of times higher than any other peak in the summation curves.

The switching point peak is also still the first peak that occurs in the positive range. Therefore, it should not be a problem to set dl far enough from the minimum of the Value198 and far above the highest peak that arises from the noise (or valve chatter).

Example 1:

Configuration example of the modified switching point detection for a valve with a distinctive switching point.

Table 555: X20CMR010 - Order data

9.26.11.2 Module description

The module is designed for measuring ambient conditions in the control cabinet as well as recording operating hours and power-on cycles. In addition, the module offers the option of storing user data directly on the module and supports blackout mode.

Functions:

- "Measuring and evaluating ambient conditions"
- "Recording operating data"
- "Internal module memory for user data"
- "Blackout mode"

Measuring and evaluating ambient conditions

The ambient conditions are continuously evaluated by the module. The duration in which individual parameters are within certain ranges is stored internally. This makes it possible, for example, to determine how long the system remained in a certain temperature range. The histograms recorded by the module can be read out by the user.

Internal module memory for user data

With 512 kB nonvolatile user memory (flash), data from the application can be saved directly on the module and also read back from the module. The data is therefore retained after the module or CPU is restarted and remains with the module in the event that the module is connected to another machine or system, for example. Data retention is maintenance-free – without batteries.

Information:

It is important to note that the internal module memory is not available in function model "Bus controller"!

Blackout mode

The integrated blackout mode ensures that module functionality is maintained even in the event of network failure.

9.26.11.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|--------------------------------|--|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | Mode RESET |
| | | | Double flash | Blackout mode active |
| | | | Blinking | Mode PREOPERATIONAL |
| | | | On | Mode RUN |
| | e | Red | Off | Module not supplied with power or everything OK |
| | e + r | Solid red / Single green flash | Invalid firmware | |
| | R | Green | Off | No data is being read from internal memory. |
| | | | On | The user is reading data from internal memory. |
| | W | Yellow | Off | No data is being written to internal memory. |
| On | | | The user is writing data to internal memory. | |

9.26.11.5 Pinout

9.26.11.6 Function description

9.26.11.6.1 Measuring and evaluating ambient conditions

The module is equipped with internal sensors to collect the following conditions:

- Relative humidity [%]
- Ambient temperature [°C]

Information:

The sampling rate is 1 s.

Since the sensor for relative humidity and ambient temperature is located directly in the module, the measured values depend on the intrinsic heating of the module and the heat radiated by neighboring modules.

The effect of this warming on the measured values can be circumvented by using an external temperature sensor on another module. The value measured with the external temperature sensor is used as a reference. With this value, the relative humidity at the position of the external temperature sensor is calculated using the Magnus formula.

$$\text{saturated water vapor pressure [Pa]} = 611.2 \cdot e^{\frac{17.62 \cdot \text{temperature}}{243.12 + \text{temperature}}}$$

$$\text{absolute humidity [g/m}^3\text{]} = \frac{\text{saturated water vapor pressure}}{461.52 \cdot (273.15 + \text{temperature})} \cdot 1000$$

$$\text{humidity [g/m}^3\text{]} = \text{absolute humidity} \cdot \text{relative humidity}$$

$$\text{relative humidity [\%]} = \frac{\text{humidity}}{\text{absolute humidity}} \cdot 100$$

Example

The following example calculates the relative humidity at the position of the external temperature sensor using the Magnus formula.

- Relative humidity in module: 20%
- Ambient temperature in module: 40°C
- External temperature sensor: 35°C

Module

$$\text{saturated water vapor pressure}_{\text{module}} = 611.2 \cdot e^{\frac{17.62 \cdot 40}{243.12 + 40}} = 7367.5 \text{ Pa}$$

$$\text{absolute humidity}_{\text{module}} = \frac{7367.5}{461.52 \cdot (273.15 + 40)} \cdot 1000 = 50.98 \text{ g/m}^3$$

$$\text{humidity}_{\text{module}} = 50.98 \cdot 0.2 = 10.2 \text{ g/m}^3$$

External temperature sensor

$$\text{saturated water vapor pressure}_{\text{ExtSensor}} = 611.2 \cdot e^{\frac{17.62 \cdot 35}{243.12 + 35}} = 5612.8 \text{ Pa}$$

$$\text{absolute humidity}_{\text{ExtSensor}} = \frac{5612.8}{461.52 \cdot (273.15 + 35)} \cdot 1000 = 39.47 \text{ g/m}^3$$

$$\text{relative humidity}_{\text{ExtSensor}} = \frac{10.2}{39.47} \cdot 100 = 25.84\%$$

In this example, a deviation of the relative humidity of approx. 6% results between the measured value in the module and the calculated value at the position of the external temperature sensor.

9.26.11.6.1.1 Additional information

The ambient conditions are recorded and evaluated in the module. The following values can be read:

- Smallest value occurred
- Largest value occurred

Information:

The values are saved to module-internal FRAM.

If needed, the values can be reset.

The registers are described in section "[Additional information](#)" on page 3227.

9.26.11.6.1.2 Histogram for relative humidity

A histogram for relative humidity is recorded in the module. The measuring range for the relative humidity is divided into 10 areas:

| Area | Relative humidity | Register |
|------|-------------------|---------------------------------------|
| 1 | 0 to <10% | RelHumHist01Entry RelHumHist01Time |
| 2 | 10 to <20% | RelHumHist02Entry RelHumHist02Time |
| 3 | 20 to <30% | RelHumHist03Entry RelHumHist03Time |
| 4 | 30 to <40% | RelHumHist04Entry RelHumHist04Time |
| 5 | 40 to <50% | RelHumHist05Entry RelHumHist05Time |
| 6 | 50 to <60% | RelHumHist06Entry RelHumHist06Time |
| 7 | 60 to <70% | RelHumHist07Entry RelHumHist07Time |
| 8 | 70 to <80% | RelHumHist08Entry RelHumHist08Time |
| 9 | 80 to <90% | RelHumHist09Entry RelHumHist09Time |
| 10 | 90 to 100% | RelHumHist10Entry RelHumHist10Time |

As soon as the relative humidity reaches one of the predefined areas, a delay time of 3 s begins. Once the delay time has expired, the entry counter is increased by 1 and the dwell time begins. The delay time prevents the counter from constantly being incremented in the crossover area.

Information:

The values are saved to module-internal FRAM.

If needed, the registers can be reset.

The registers are described in section "[Relative humidity](#)" on page 3228.

9.26.11.6.1.3 Histogram for ambient temperature

A histogram for ambient temperature is recorded in the module. The measuring range for the ambient temperature is divided into 12 areas:

| Area | Ambient temperature | Register |
|------|---------------------|-----------------------------------|
| 1 | <-20°C | TempHist01Entry TempHist01Time |
| 2 | -20 to <-10°C | TempHist02Entry TempHist02Time |
| 3 | -10 to <0°C | TempHist03Entry TempHist03Time |
| 4 | 0 to <10°C | TempHist04Entry TempHist04Time |
| 5 | 10 to <20°C | TempHist05Entry TempHist05Time |
| 6 | 20 to <30°C | TempHist06Entry TempHist06Time |
| 7 | 30 to <40°C | TempHist07Entry TempHist07Time |
| 8 | 40 to <50°C | TempHist08Entry TempHist08Time |
| 9 | 50 to <60°C | TempHist09Entry TempHist09Time |
| 10 | 60 to <70°C | TempHist10Entry TempHist10Time |
| 11 | 70 to <80°C | TempHist11Entry TempHist11Time |
| 12 | ≥80°C | TempHist12Entry TempHist12Time |

As soon as the ambient temperature reaches one of the predefined areas, a delay time of 3 s begins. Once the delay time has expired, the entry counter is increased by 1 and the dwell time begins. The delay time prevents the counter from constantly being incremented in the crossover area.

Information:

The values are saved to module-internal FRAM.

If needed, the registers can be reset.

The registers are described in section "[Ambient temperature](#)" on page 3228.

9.26.11.6.2 Recording operating data

The following operating data is collected by the module:

- Operating time with active connection to network master
- Operating time without active connection to network master (blackout mode)
- Total operating time
- Number of power-on cycles

Information:

The values are saved to module-internal FRAM.

If needed, the operating data can be reset.

The registers are described in section "[Operating data](#)" on page 3227.

9.26.11.6.3 Internal module memory for user data

9.26.11.6.3.1 General information

The module is equipped with 512 kB nonvolatile internal flash memory that can be used by the application. Data can be saved directly to the module and then read back. This makes it possible to store recipe data or production information about the machine on the module, for example.

9.26.11.6.3.2 Operation

The module's memory interface is based on Flatstream communication. Operation takes place using library "AsFltGen".

Information:

For more information about library "AsFltGen", see Automation Help.

Information:

The following points must be observed:

- Up to 256 bytes can be read or written per read or write command. These 256 bytes represent a page. If more than 256 bytes must be read or written, then a consecutive sequence of commands and memory management must be implemented in the application.
- The erase command is based on sectors. One sector is 64 kB. This corresponds to 256 pages. The entire sector containing the specified address is erased. The flash memory is divided into a total of 8 sectors (8 x 64 kB = 512 kB).
- In order to overwrite data, the corresponding sector must first be erased. Only then can the new data be saved.
- Memory can be arranged as needed. A separate sector should be used for data that is overwritten regularly.

9.26.11.6.3.3 Commands

Protocol

A header precedes each command. The data follows the header and depends on the command.

Header

Each request or response begins with a 16-byte header. The following elements must be defined in the header:

| Element | Data type | Activity | Description |
|--------------------|-----------|-------------|---|
| Code | USINT | Requirement | Defines the command: "r" ... Read data (ASCII code 0x72) "w" ... Write data (ASCII code 0x77) "e" ... Erase data (ASCII code 0x65) |
| | | Response | The command code contained in the request is sent back. |
| Consecutive number | USINT | Requirement | Unrestricted use. The consecutive number is important, for example, if more than 256 bytes must be read or written. In this case, the user must implement a sequential series of commands and memory management in the application. |
| | | Response | The number contained in the request is sent back. |
| Status | UINT | Requirement | Not used: The byte is not evaluated. |
| | | Response | Status response: 0x0000 ... Command executed successfully 0x8001 ... Invalid: General fault 0x8002 ... Invalid address 0x8003 ... Invalid size 0x8004 ... Flash memory busy 0x8006 ... Flash memory timeout |
| Address | UDINT | Requirement | Starting address from which data should be read or written. |
| | | Response | The starting address contained in the request is sent back. |
| Data size | UDINT | Requirement | Size of the data to be read or written. |
| | | Response | The data size contained in the request is sent back. |
| Reserve | UDINT | Reserved | |

Write data

| Action | Description |
|-------------|---|
| Requirement | In order to save data to the module, the header must be prepared for communication. The data is appended directly to the header. The header and data must be specified to function block "fitWrite" as a transmit buffer.  |
| Response | The module's response – the returned header – is stored in the receive buffer using function block "fitRead" and can be evaluated by the application.  |

Read data

| Action | Description |
|-------------|--|
| Requirement | In order to read data from the module, the header must be prepared for communication. The header must be specified to function block "fitWrite" as a transmit buffer.  |
| Response | The module's response – the returned header and data – is stored in the receive buffer using function block "fitRead" and can be evaluated by the application.  |

Erasing a sector

| Action | Description |
|-------------|---|
| Requirement | In order to erase an area of the module's flash memory, the header must be prepared for communication. The entire 64 kB sector containing the specified address is erased. The header must be specified to function block "fitWrite" as a transmit buffer.  |
| Response | The module's response – the returned header – is stored in the receive buffer using function block "fitRead" and can be evaluated by the application.  |

9.26.11.6.4 Blackout mode

For a description of blackout mode, see "[Blackout mode](#)" on page 3794.

9.26.11.7 Register description

9.26.11.7.1 Using this module with SGC target systems

Information:

It is not possible to use the module with SGC target systems.

9.26.11.7.2 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

| 4412 + N*16 | - | TempHist0NTime (index N = 1 to 12) | UDINT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.26.11.7.4.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.11.7.4.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.26.11.7.5 Controller

9.26.11.7.5.1 Reset additional information and data point histograms

Name:

ClrStatistics_OperatingData

ClrStatistics_RelHumidity

ClrStatistics_Temperature

Setting the respective bit in the register resets operating data, information and histograms. Procedure:

- Set the bit for resetting the desired data
- The bit must remain set until the registers have been reset
- As soon as the user has determined that the data has been reset, then the bit for resetting the data can be deleted
- If the bit for resetting the data is not deleted, the data will be permanently set to 0

Information:

It can take up to 1 s until the delete operation for the data is executed.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|--------------|
| 0 | ClrStatistics_OperatingData Reset operating data | 0 | Do not reset |
| | | 1 | Reset |
| 1 | ClrStatistics_RelHumidity Resets information and histograms for relative humidity | 0 | Do not reset |
| | | 1 | Reset |
| 2 | ClrStatistics_Temperature Resets information and histograms for ambient temperature | 0 | Do not reset |
| | | 1 | Reset |
| 3 - 15 | Reserved | 0 | |

9.26.11.7.6 Measured values

9.26.11.7.6.1 Relative humidity

Name:

RelHumidity

An internal sensor measures the relative humidity in the area.

| Data type | Values | Information |
|-----------|----------|--------------------------------------|
| INT | 0 to 100 | Relative humidity [%], resolution 1% |

9.26.11.7.6.2 Ambient temperature

Name:

Temperature

An internal sensor measures the ambient temperature.

| Data type | Values | Information |
|-----------|--------------|--|
| INT | -250 to 1250 | Ambient temperature [°C], resolution 0.1°C |

9.26.11.7.7 Additional information

Information:

The following points must be observed:

- Data recorded on the module is saved in intervals of 10 s.
- When resetting the values, it can take up to 1 s until the delete operation is executed (see register "ClrStatistics" on page 3226).

9.26.11.7.7.1 Operating data

Name:

OnTimeConnected
OnTimeDisconnected
OnTimeCombined
PowerCycles

The respective operating data is output in these registers. If needed, the values can be reset using register "ClrStatistics" on page 3226.

| Register | Data type | Values | Information |
|--------------------|-----------|--------------------|---|
| OnTimeConnected | UDINT | 0 to 4,294,967,295 | Operating time during which the module was actively connected to the network master [s], resolution 1 s |
| OnTimeDisconnected | UDINT | 0 to 4,294,967,295 | Operating time during which the module was not actively connected to the network master [s] (blackout mode), resolution 1 s |
| OnTimeCombined | UDINT | 0 to 4,294,967,295 | Total operating time of the module [s], resolution 1 s |
| PowerCycles | UDINT | 0 to 4,294,967,295 | Number of power-on cycles |

9.26.11.7.7.2 Relative humidity

Name:

RelHumidityMin
RelHumidityMax

Information about the relative humidity is output in these registers. The sampling interval is 1 s. If needed, the values can be reset using register "ClrStatistics" on page 3226.

| Register | Data type | Values | Information |
|----------------|-----------|----------|---|
| RelHumidityMin | INT | 0 to 100 | Smallest value that occurred [%], resolution 1% |
| RelHumidityMax | INT | 0 to 100 | Largest value that occurred [%], resolution 1% |

9.26.11.7.7.3 Ambient temperature

Name:

TemperatureMin
TemperatureMax

Information about the ambient temperature is output in these registers. The sampling interval is 1 s. If needed, the values can be reset using register "ClrStatistics" on page 3226.

| Register | Data type | Values | Information |
|----------------|-----------|--------------|--|
| TemperatureMin | INT | -250 to 1250 | Lowest value that occurred [°C], resolution 0.1°C |
| TemperatureMax | INT | -250 to 1250 | Highest value that occurred [°C], resolution 0.1°C |

9.26.11.7.8 Data point histogram

9.26.11.7.8.1 Relative humidity

Name:

RelHumHist01Entry to RelHumHist10Entry

RelHumHist01Time to RelHumHist10Time

The relative humidity histogram data recorded on the module is displayed on these registers. If needed, the values can be reset using register "[ClrStatistics](#)" on page 3226.

| Register | Data type | Values | Information |
|--|-----------|--------------------|--|
| RelHumHist01Entry to RelHumHist10Entry | UDINT | 0 to 4,294,967,295 | Entry counter for the corresponding area |
| RelHumHist01Time to RelHumHist10Time | UDINT | 0 to 4,294,967,295 | Dwell time in corresponding area [s], resolution 1 s |

9.26.11.7.8.2 Ambient temperature

Name:

TempHist01Entry to TempHist12Entry

TempHist01Time to TempHist12Time

The ambient temperature histogram data recorded on the module is displayed on these registers. If needed, the values can be reset using register "[ClrStatistics](#)" on page 3226.

| Register | Data type | Values | Information |
|------------------------------------|-----------|--------------------|--|
| TempHist01Entry to TempHist12Entry | UDINT | 0 to 4,294,967,295 | Entry counter for the corresponding area |
| TempHist01Time to TempHist12Time | UDINT | 0 to 4,294,967,295 | Dwell time in corresponding area [s], resolution 1 s |

9.26.11.7.9 Flatstream communication

For a description of Flatstream communication, see "[Flatstream communication](#)" on page 3802

9.26.11.7.10 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|--------------------|--|
| 200 μ s | |

9.26.11.7.11 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|-------------------------------------|--------|
| Temperature and relative humidity | 1 s |
| User flash Flatstream communication | <10 ms |

9.26.12 X20CMR100

Data sheet version: 1.05

9.26.12.1 Order data

| Model number | Short description | Figure |

Table 557: X20CMR100 - Order data

9.26.12.2 Module description

The module is designed for measuring ambient conditions in the control cabinet as well as recording operating hours and power-on cycles. In addition, the module is equipped with a Technology Guard and supports blackout mode.

Functions:

- "Measuring and evaluating ambient conditions"
- "Recording operating data"
- "Technology Guarding"
- "Blackout mode"

Measuring and evaluating ambient conditions

The ambient conditions are continuously evaluated by the module. The duration in which individual parameters are within certain ranges is stored internally. This makes it possible, for example, to determine how long the system remained in a certain temperature range. The histograms recorded by the module can be read out by the user.

Technology Guarding

With the integrated Technology Guard, it is possible to implement license protection directly via the module instead of the USB dongle. The same functions can be used as with the USB dongle.

Information:

- **Automation Runtime C4.44 or later is required to use the functions of the Technology Guard.**
- **It is important to note that the Technology Guard is not available in function model "Bus controller"!**
- **This module is not suitable for controller redundancy applications.**

Blackout mode

The integrated blackout mode ensures that module functionality is maintained even in the event of network failure.

9.26.12.3 Technical data

| Model number | X20CMR100 |
|--|--|

9.26.12.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|--------------------------------|------------------|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | Mode RESET |
| | | | Double flash | Blackout mode active |
| | | | Blinking | Mode PREOPERATIONAL |
| | | | On | Mode RUN |
| | e | Red | Off | Module not supplied with power or everything OK |
| | e + r | Solid red / Single green flash | Invalid firmware | |
| | TG | Yellow | Off | Technology Guard is not accessed |
| | | | On | The module accesses the Technology Guard |

9.26.12.5 Pinout

9.26.12.6 Function description

9.26.12.6.1 Measuring and evaluating ambient conditions

The module is equipped with internal sensors to collect the following conditions:

- Relative humidity [%]
- Ambient temperature [°C]

Information:

The sampling rate is 1 s.

Since the sensor for relative humidity and ambient temperature is located directly in the module, the measured values depend on the intrinsic heating of the module and the heat radiated by neighboring modules.

The effect of this warming on the measured values can be circumvented by using an external temperature sensor on another module. The value measured with the external temperature sensor is used as a reference. With this value, the relative humidity at the position of the external temperature sensor is calculated using the Magnus formula.

$$\text{saturated water vapor pressure [Pa]} = 611.2 \cdot e^{\frac{17.62 \cdot \text{temperature}}{243.12 + \text{temperature}}}$$

$$\text{absolute humidity [g/m}^3\text{]} = \frac{\text{saturated water vapor pressure}}{461.52 \cdot (273.15 + \text{temperature})} \cdot 1000$$

$$\text{humidity [g/m}^3\text{]} = \text{absolute humidity} \cdot \text{relative humidity}$$

$$\text{relative humidity [\%]} = \frac{\text{humidity}}{\text{absolute humidity}} \cdot 100$$

Example

The following example calculates the relative humidity at the position of the external temperature sensor using the Magnus formula.

- Relative humidity in module: 20%
- Ambient temperature in module: 40°C
- External temperature sensor: 35°C

Module

$$\text{saturated water vapor pressure}_{\text{module}} = 611.2 \cdot e^{\frac{17.62 \cdot 40}{243.12 + 40}} = 7367.5 \text{ Pa}$$

$$\text{absolute humidity}_{\text{module}} = \frac{7367.5}{461.52 \cdot (273.15 + 40)} \cdot 1000 = 50.98 \text{ g/m}^3$$

$$\text{humidity}_{\text{module}} = 50.98 \cdot 0.2 = 10.2 \text{ g/m}^3$$

External temperature sensor

$$\text{saturated water vapor pressure}_{\text{ExtSensor}} = 611.2 \cdot e^{\frac{17.62 \cdot 35}{243.12 + 35}} = 5612.8 \text{ Pa}$$

$$\text{absolute humidity}_{\text{ExtSensor}} = \frac{5612.8}{461.52 \cdot (273.15 + 35)} \cdot 1000 = 39.47 \text{ g/m}^3$$

$$\text{relative humidity}_{\text{ExtSensor}} = \frac{10.2}{39.47} \cdot 100 = 25.84\%$$

In this example, a deviation of the relative humidity of approx. 6% results between the measured value in the module and the calculated value at the position of the external temperature sensor.

9.26.12.6.1.1 Additional information

The ambient conditions are recorded and evaluated in the module. The following values can be read:

- Smallest value occurred
- Largest value occurred

Information:

The values are saved to module-internal FRAM.

If needed, the values can be reset.

The registers are described in section "[Additional information](#)" on page 3240.

9.26.12.6.1.2 Histogram for relative humidity

A histogram for relative humidity is recorded in the module. The measuring range for the relative humidity is divided into 10 areas:

| Area | Relative humidity | Register |
|------|-------------------|---------------------------------------|
| 1 | 0 to <10% | RelHumHist01Entry RelHumHist01Time |
| 2 | 10 to <20% | RelHumHist02Entry RelHumHist02Time |
| 3 | 20 to <30% | RelHumHist03Entry RelHumHist03Time |
| 4 | 30 to <40% | RelHumHist04Entry RelHumHist04Time |
| 5 | 40 to <50% | RelHumHist05Entry RelHumHist05Time |
| 6 | 50 to <60% | RelHumHist06Entry RelHumHist06Time |
| 7 | 60 to <70% | RelHumHist07Entry RelHumHist07Time |
| 8 | 70 to <80% | RelHumHist08Entry RelHumHist08Time |
| 9 | 80 to <90% | RelHumHist09Entry RelHumHist09Time |
| 10 | 90 to 100% | RelHumHist10Entry RelHumHist10Time |

As soon as the relative humidity reaches one of the predefined areas, a delay time of 3 s begins. Once the delay time has expired, the entry counter is increased by 1 and the dwell time begins. The delay time prevents the counter from constantly being incremented in the crossover area.

Information:

The values are saved to module-internal FRAM.

If needed, the registers can be reset.

The registers are described in section "[Relative humidity](#)" on page 3241.

9.26.12.6.1.3 Histogram for ambient temperature

A histogram for ambient temperature is recorded in the module. The measuring range for the ambient temperature is divided into 12 areas:

| Area | Ambient temperature | Register |
|------|---------------------|-----------------------------------|
| 1 | <-20°C | TempHist01Entry TempHist01Time |
| 2 | -20 to <-10°C | TempHist02Entry TempHist02Time |
| 3 | -10 to <0°C | TempHist03Entry TempHist03Time |
| 4 | 0 to <10°C | TempHist04Entry TempHist04Time |
| 5 | 10 to <20°C | TempHist05Entry TempHist05Time |
| 6 | 20 to <30°C | TempHist06Entry TempHist06Time |
| 7 | 30 to <40°C | TempHist07Entry TempHist07Time |
| 8 | 40 to <50°C | TempHist08Entry TempHist08Time |
| 9 | 50 to <60°C | TempHist09Entry TempHist09Time |
| 10 | 60 to <70°C | TempHist10Entry TempHist10Time |
| 11 | 70 to <80°C | TempHist11Entry TempHist11Time |
| 12 | ≥80°C | TempHist12Entry TempHist12Time |

As soon as the ambient temperature reaches one of the predefined areas, a delay time of 3 s begins. Once the delay time has expired, the entry counter is increased by 1 and the dwell time begins. The delay time prevents the counter from constantly being incremented in the crossover area.

Information:

The values are saved to module-internal FRAM.

If needed, the registers can be reset.

The registers are described in section "[Ambient temperature](#)" on page 3241.

9.26.12.6.2 Recording operating data

The following operating data is collected by the module:

- Operating time with active connection to network master
- Operating time without active connection to network master (blackout mode)
- Total operating time
- Number of power-on cycles

Information:

The values are saved to module-internal FRAM.

If needed, the operating data can be reset.

The registers are described in section "[Operating data](#)" on page 3240.

9.26.12.6.3 Technology Guarding

This module is equipped with a Technology Guard. The Technology Guard integrated in the module results in the following advantages:

- USB interface not required for the Technology Guard
- Module can be used when no additional USB interfaces are available
- Module can be used when USB interfaces are prohibited for security reasons

Technology Guarding for the module is based on the same mechanism as the USB dongle connected to the CPU. The licenses themselves are verified in Automation Runtime on the target system. Automation Runtime will signal a license violation if the system has licensing requirements that are not covered by the licenses on the Technology Guard.

The Technology Guard provides the following possibilities:

- 2 tamper-resistant operating hours counters
- Possible to store multiple B&R licenses
- Customized license storage possible
- Customized data storage possible

Information:

The extended user-specific operation of the Technology Guard is handled via library "AsGuard". For more information about library "AsGuard", see Automation Help.

Information:

Automation Runtime C4.44 or later is required to use the functions of the Technology Guard.

9.26.12.6.4 Blackout mode

For a description of blackout mode, see "[Blackout mode](#)" on page 3794.

9.26.12.7 Register description

9.26.12.7.1 Using this module with SGC target systems

Information:

It is not possible to use the module with SGC target systems.

9.26.12.7.2 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.26.12.7.3 Function model 0 - Standard

| Register | Description | Data type | Read | | Write | |

| 4412 + N*16 | - | TempHist0NTime (index N = 1 to 12) | UDINT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.26.12.7.4.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.12.7.4.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.26.12.7.5 Controller

9.26.12.7.5.1 Reset additional information and data point histograms

Name:

ClrStatistics_OperatingData

ClrStatistics_RelHumidity

ClrStatistics_Temperature

Setting the respective bit in the register resets operating data, information and histograms. Procedure:

- Set the bit for resetting the desired data
- The bit must remain set until the registers have been reset
- As soon as the user has determined that the data has been reset, then the bit for resetting the data can be deleted
- If the bit for resetting the data is not deleted, the data will be permanently set to 0

Information:

It can take up to 1 s until the delete operation for the data is executed.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|--------------|
| 0 | ClrStatistics_OperatingData Resets operating data | 0 | Do not reset |
| | | 1 | Reset |
| 1 | ClrStatistics_RelHumidity Resets information and histograms for relative humidity | 0 | Do not reset |
| | | 1 | Reset |
| 2 | ClrStatistics_Temperature Resets information and histograms for ambient temperature | 0 | Do not reset |
| | | 1 | Reset |
| 3 - 15 | Reserved | 0 | |

9.26.12.7.6 Measured values

9.26.12.7.6.1 Relative humidity

Name:

RelHumidity

An internal sensor measures the relative humidity in the area.

| Data type | Values | Information |
|-----------|----------|--------------------------------------|
| INT | 0 to 100 | Relative humidity [%], resolution 1% |

9.26.12.7.6.2 Ambient temperature

Name:

Temperature

An internal sensor measures the ambient temperature.

| Data type | Values | Information |
|-----------|--------------|--|
| INT | -250 to 1250 | Ambient temperature [°C], resolution 0.1°C |

9.26.12.7.7 Additional information

Information:

The following points must be observed:

- Data recorded on the module is saved in intervals of 10 s.
- When resetting the values, it can take up to 1 s until the delete operation is executed (see register "ClrStatistics" on page 3239).

9.26.12.7.7.1 Operating data

Name:

OnTimeConnected
OnTimeDisconnected
OnTimeCombined
PowerCycles

The respective operating data is output in these registers. If needed, the values can be reset using register "ClrStatistics" on page 3239.

| Register | Data type | Values | Information |
|--------------------|-----------|--------------------|---|
| OnTimeConnected | UDINT | 0 to 4,294,967,295 | Operating time during which the module was actively connected to the network master [s], resolution 1 s |
| OnTimeDisconnected | UDINT | 0 to 4,294,967,295 | Operating time during which the module was not actively connected to the network master [s] (blackout mode), resolution 1 s |
| OnTimeCombined | UDINT | 0 to 4,294,967,295 | Total operating time of the module [s], resolution 1 s |
| PowerCycles | UDINT | 0 to 4,294,967,295 | Number of power-on cycles |

9.26.12.7.7.2 Relative humidity

Name:

RelHumidityMin
RelHumidityMax

Information about the relative humidity is output in these registers. The sampling interval is 1 s. If needed, the values can be reset using register "ClrStatistics" on page 3239.

| Register | Data type | Values | Information |
|----------------|-----------|----------|---|
| RelHumidityMin | INT | 0 to 100 | Smallest value that occurred [%], resolution 1% |
| RelHumidityMax | INT | 0 to 100 | Largest value that occurred [%], resolution 1% |

9.26.12.7.7.3 Ambient temperature

Name:

TemperatureMin
TemperatureMax

Information about the ambient temperature is output in these registers. The sampling interval is 1 s. If needed, the values can be reset using register "ClrStatistics" on page 3239.

| Register | Data type | Values | Information |
|----------------|-----------|--------------|--|
| TemperatureMin | INT | -250 to 1250 | Lowest value that occurred [°C], resolution 0.1°C |
| TemperatureMax | INT | -250 to 1250 | Highest value that occurred [°C], resolution 0.1°C |

9.26.12.7.8 Data point histogram

9.26.12.7.8.1 Relative humidity

Name:

RelHumHist01Entry to RelHumHist10Entry

RelHumHist01Time to RelHumHist10Time

The relative humidity histogram data recorded on the module is displayed on these registers. If needed, the values can be reset using register "[ClrStatistics](#)" on page 3239.

| Register | Data type | Values | Information |
|--|-----------|--------------------|--|
| RelHumHist01Entry to RelHumHist10Entry | UDINT | 0 to 4,294,967,295 | Entry counter for the corresponding area |
| RelHumHist01Time to RelHumHist10Time | UDINT | 0 to 4,294,967,295 | Dwell time in corresponding area [s], resolution 1 s |

9.26.12.7.8.2 Ambient temperature

Name:

TempHist01Entry to TempHist12Entry

TempHist01Time to TempHist12Time

The ambient temperature histogram data recorded on the module is displayed on these registers. If needed, the values can be reset using register "[ClrStatistics](#)" on page 3239.

| Register | Data type | Values | Information |
|------------------------------------|-----------|--------------------|--|
| TempHist01Entry to TempHist12Entry | UDINT | 0 to 4,294,967,295 | Entry counter for the corresponding area |
| TempHist01Time to TempHist12Time | UDINT | 0 to 4,294,967,295 | Dwell time in corresponding area [s], resolution 1 s |

9.26.12.7.9 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.26.12.7.10 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|-------------------------------------|--------|
| Temperature and relative humidity | 1 s |
| User flash Flatstream communication | <10 ms |

Table 559: X20CMR111 - Order data

9.26.13.2 Module description

The module is designed for measuring ambient conditions in the control cabinet as well as recording operating hours and power-on cycles. In addition, the module offers the option of storing user data directly on the module, is equipped with a Technology Guard as well as inputs/outputs and supports blackout mode.

Functions:

- [Measuring and evaluating ambient conditions](#)
- [Recording operating data](#)
- [Internal module memory for user data](#)
- [Technology Guarding](#)
- [Configuration of inputs](#)
- [Blackout mode](#)

Measuring and evaluating ambient conditions

The ambient conditions are continuously evaluated by the module. The duration in which individual parameters are within certain ranges is stored internally. This makes it possible, for example, to determine how long the system remained in a certain temperature range. The histograms recorded by the module can be read out by the user.

Internal module memory for user data

With 512 kB nonvolatile user memory (flash), data from the application can be saved directly on the module and also read back from the module. The data is therefore retained after the module or CPU is restarted and remains with the module in the event that the module is connected to another machine or system, for example. Data retention is maintenance-free – without batteries.

Information:

It is important to note that the internal module memory is not available in function model "Bus controller"!

Technology Guarding

With the integrated Technology Guard, it is possible to implement license protection directly via the module instead of the USB dongle. The same functions can be used as with the USB dongle.

Information:

- **Automation Runtime C4.44 or later is required to use the functions of the Technology Guard.**
- **It is important to note that the Technology Guard is not available in function model "Bus controller"!**
- **This module is not suitable for controller redundancy applications.**

Inputs/Outputs

The module is equipped with 2 inputs for PT1000 temperature sensors, 2 digital inputs (24 VDC) and 1 digital output (24 VDC).

Blackout mode

The integrated blackout mode ensures that module functionality is maintained even in the event of network failure.

9.26.13.7.3 PT1000 temperature inputs

9.26.13.8 Function description

9.26.13.8.1 Measuring and evaluating ambient conditions

The module is equipped with internal sensors to collect the following conditions:

| Condition | Unit | Sampling rate |
|---------------------|-------|---------------|
| Relative humidity | [%] | 1 s |
| Ambient temperature | [°C] | 1 s |
| Acceleration | [g] | Typ. 10 ms |
| Rotation | [dps] | Typ. 10 ms |

9.26.13.8.1.1 Relative humidity and ambient temperature

Since the sensor for relative humidity and ambient temperature is located directly in the module, the measured values depend on the intrinsic heating of the module and the heat radiated by neighboring modules.

The effect of this warming on the measured values can be circumvented by connecting an external temperature sensor on one of the temperature sensors on the module. The value measured with the external temperature sensor is used as a reference. With this value, the relative humidity at the position of the external temperature sensor is calculated using the Magnus formula.

$$\text{saturated water vapor pressure [Pa]} = 611.2 \cdot e^{\frac{17.62 \cdot \text{temperature}}{243.12 + \text{temperature}}}$$

$$\text{absolute humidity [g/m}^3\text{]} = \frac{\text{saturated water vapor pressure}}{461.52 \cdot (273.15 + \text{temperature})} \cdot 1000$$

$$\text{humidity [g/m}^3\text{]} = \text{absolute humidity} \cdot \text{relative humidity}$$

$$\text{relative humidity [\%]} = \frac{\text{humidity}}{\text{absolute humidity}} \cdot 100$$

Example

The following example calculates the relative humidity at the position of the external temperature sensor using the Magnus formula.

- Relative humidity in module: 20%
- Ambient temperature in module: 40°C
- External temperature sensor: 35°C

Module

$$\text{saturated water vapor pressure}_{\text{module}} = 611.2 \cdot e^{\frac{17.62 \cdot 40}{243.12 + 40}} = 7367.5 \text{ Pa}$$

$$\text{absolute humidity}_{\text{module}} = \frac{7367.5}{461.52 \cdot (273.15 + 40)} \cdot 1000 = 50.98 \text{ g/m}^3$$

$$\text{humidity}_{\text{module}} = 50.98 \cdot 0.2 = 10.2 \text{ g/m}^3$$

External temperature sensor

$$\text{saturated water vapor pressure}_{\text{ExtSensor}} = 611.2 \cdot e^{\frac{17.62 \cdot 35}{243.12 + 35}} = 5612.8 \text{ Pa}$$

$$\text{absolute humidity}_{\text{ExtSensor}} = \frac{5612.8}{461.52 \cdot (273.15 + 35)} \cdot 1000 = 39.47 \text{ g/m}^3$$

$$\text{relative humidity}_{\text{ExtSensor}} = \frac{10.2}{39.47} \cdot 100 = 25.84\%$$

In this example, a deviation of the relative humidity of approx. 6% results between the measured value in the module and the calculated value at the position of the external temperature sensor.

9.26.13.8.1.2 Acceleration and rotation

Acceleration and rotation measured by the internal sensor are returned as raw values. The conversion is to be carried out in the application.

| Measured size | Conversion |
|---------------|--|
| Acceleration | 16 g = 32767 -16 g = -32768 |
| Rotation | 2000 dps = 32767 -2000 dps = -32768 |

9.26.13.8.1.3 Additional information

The ambient conditions are recorded and evaluated in the module. The following values can be read:

- Smallest value occurred
- Largest value occurred

Information:

The values are saved to module-internal FRAM.

If needed, the values can be reset.

The registers are described in section ["Additional information" on page 3263](#).

9.26.13.8.1.4 Histogram for relative humidity

A histogram for relative humidity is recorded in the module. The measuring range for the relative humidity is divided into 10 areas:

| Area | Relative humidity | Register |
|------|-------------------|---------------------------------------|
| 1 | 0 to <10% | RelHumHist01Entry RelHumHist01Time |
| 2 | 10 to <20% | RelHumHist02Entry RelHumHist02Time |
| 3 | 20 to <30% | RelHumHist03Entry RelHumHist03Time |
| 4 | 30 to <40% | RelHumHist04Entry RelHumHist04Time |
| 5 | 40 to <50% | RelHumHist05Entry RelHumHist05Time |
| 6 | 50 to <60% | RelHumHist06Entry RelHumHist06Time |
| 7 | 60 to <70% | RelHumHist07Entry RelHumHist07Time |
| 8 | 70 to <80% | RelHumHist08Entry RelHumHist08Time |
| 9 | 80 to <90% | RelHumHist09Entry RelHumHist09Time |
| 10 | 90 to 100% | RelHumHist10Entry RelHumHist10Time |

As soon as the relative humidity reaches one of the predefined areas, a delay time of 3 s begins. Once the delay time has expired, the entry counter is increased by 1 and the dwell time begins. The delay time prevents the counter from constantly being incremented in the crossover area.

Information:

The values are saved to module-internal FRAM.

If needed, the registers can be reset.

The registers are described in section ["Relative humidity" on page 3265](#).

9.26.13.8.1.5 Histogram for ambient temperature

A histogram for ambient temperature is recorded in the module. The measuring range for the ambient temperature is divided into 12 areas:

| Area | Ambient temperature | Register |
|------|---------------------|-----------------------------------|
| 1 | <-20°C | TempHist01Entry TempHist01Time |
| 2 | -20 to <-10°C | TempHist02Entry TempHist02Time |
| 3 | -10 to <0°C | TempHist03Entry TempHist03Time |
| 4 | 0 to <10°C | TempHist04Entry TempHist04Time |
| 5 | 10 to <20°C | TempHist05Entry TempHist05Time |
| 6 | 20 to <30°C | TempHist06Entry TempHist06Time |
| 7 | 30 to <40°C | TempHist07Entry TempHist07Time |
| 8 | 40 to <50°C | TempHist08Entry TempHist08Time |
| 9 | 50 to <60°C | TempHist09Entry TempHist09Time |
| 10 | 60 to <70°C | TempHist10Entry TempHist10Time |
| 11 | 70 to <80°C | TempHist11Entry TempHist11Time |
| 12 | ≥80°C | TempHist12Entry TempHist12Time |

As soon as the ambient temperature reaches one of the predefined areas, a delay time of 3 s begins. Once the delay time has expired, the entry counter is increased by 1 and the dwell time begins. The delay time prevents the counter from constantly being incremented in the crossover area.

Information:

The values are saved to module-internal FRAM.

If needed, the registers can be reset.

The registers are described in section "[Ambient temperature](#)" on page 3265.

9.26.13.8.1.6 Histogram for acceleration

A histogram for acceleration is recorded in the module. The measurement range for the acceleration is divided into 8 areas:

| Area | Acceleration | Register |
|------|---------------|-------------------------------------|
| 1 | -16 to <-12 g | AccHist0N01Entry AccHist0N01Time |
| 2 | -12 to <-8 g | AccHist0N02Entry AccHist0N02Time |
| 3 | -8 to <-4 g | AccHist0N03Entry AccHist0N03Time |
| 4 | -4 to <0 g | AccHist0N04Entry AccHist0N04Time |
| 5 | 0 to <4 g | AccHist0N05Entry AccHist0N05Time |
| 6 | 4 to <8 g | AccHist0N06Entry AccHist0N06Time |
| 7 | 8 to <12 g | AccHist0N07Entry AccHist0N07Time |
| 8 | 12 to 16 g | AccHist0N08Entry AccHist0N08Time |

Legend: N = 1 to 3

As soon as the acceleration reaches one of the predefined areas, a delay time of 3 s begins. Once the delay time has expired, the entry counter is increased by 1 and the dwell time begins. The delay time prevents the counter from constantly being incremented in the crossover area.

Information:

The values are saved to module-internal FRAM.

If needed, the registers can be reset.

The registers are described in section "[Acceleration](#)" on page 3265.

9.26.13.8.1.7 Histogram for rotation

A histogram for rotation is recorded in the module. The measurement range for the rotation is divided into 8 areas:

| Area | Rotation | Register |
|------|---------------------|---|
| 1 | -2000 to <-1500 dps | RotationHist0N01Entry RotationHist0N01Time |
| 2 | -1500 to <-1000 dps | RotationHist0N02Entry RotationHist0N02Time |
| 3 | -1000 to <-500 dps | RotationHist0N03Entry RotationHist0N03Time |
| 4 | -500 to <0 dps | RotationHist0N04Entry RotationHist0N04Time |
| 5 | 0 to <500 dps | RotationHist0N05Entry RotationHist0N05Time |
| 6 | 500 to <1000 dps | RotationHist0N06Entry RotationHist0N06Time |
| 7 | 1000 to <1500 dps | RotationHist0N07Entry RotationHist0N07Time |
| 8 | 1500 to 2000 dps | RotationHist0N08Entry RotationHist0N08Time |

Legend: N = 1 to 3

As soon as the rotation reaches one of the predefined areas, a delay time of 3 s begins. Once the delay time has expired, the entry counter is increased by 1 and the dwell time begins. The delay time prevents the counter from constantly being incremented in the crossover area.

Information:

The values are saved to module-internal FRAM.

If needed, the registers can be reset.

The registers are described in section ["Rotation" on page 3265](#).

9.26.13.8.2 Recording operating data

The following operating data is collected by the module:

- Operating time with active connection to network master
- Operating time without active connection to network master (blackout mode)
- Total operating time
- Number of power-on cycles

Information:

The values are saved to module-internal FRAM.

If needed, the operating data can be reset.

The registers are described in section ["Operating data" on page 3263](#).

9.26.13.8.3 Internal module memory for user data

9.26.13.8.3.1 General information

The module is equipped with 512 kB nonvolatile internal flash memory that can be used by the application. Data can be saved directly to the module and then read back. This makes it possible to store recipe data or production information about the machine on the module, for example.

9.26.13.8.3.2 Operation

The module's memory interface is based on Flatstream communication. Operation takes place using library "AsFitGen".

Information:

For more information about library "AsFitGen", see [Automation Help](#).

Information:

The following points must be observed:

- Up to 256 bytes can be read or written per read or write command. These 256 bytes represent a page. If more than 256 bytes must be read or written, then a consecutive sequence of commands and memory management must be implemented in the application.
- The erase command is based on sectors. One sector is 64 kB. This corresponds to 256 pages. The entire sector containing the specified address is erased. The flash memory is divided into a total of 8 sectors (8 x 64 kB = 512 kB).
- In order to overwrite data, the corresponding sector must first be erased. Only then can the new data be saved.
- Memory can be arranged as needed. A separate sector should be used for data that is overwritten regularly.

9.26.13.8.3.3 Commands

Protocol

A header precedes each command. The data follows the header and depends on the command.

Header

Each request or response begins with a 16-byte header. The following elements must be defined in the header:

| Element | Data type | Activity | Description |
|--------------------|-----------|-------------|---|
| Code | USINT | Requirement | Defines the command: "r" ... Read data (ASCII code 0x72) "w" ... Write data (ASCII code 0x77) "e" ... Erase data (ASCII code 0x65) |
| | | Response | The command code contained in the request is sent back. |
| Consecutive number | USINT | Requirement | Unrestricted use. The consecutive number is important, for example, if more than 256 bytes must be read or written. In this case, the user must implement a sequential series of commands and memory management in the application. |
| | | Response | The number contained in the request is sent back. |
| Status | UINT | Requirement | Not used: The byte is not evaluated. |
| | | Response | Status response: 0x0000 ... Command executed successfully 0x8001 ... Invalid: General fault 0x8002 ... Invalid address 0x8003 ... Invalid size 0x8004 ... Flash memory busy 0x8006 ... Flash memory timeout |
| Address | UDINT | Requirement | Starting address from which data should be read or written. |
| | | Response | The starting address contained in the request is sent back. |
| Data size | UDINT | Requirement | Size of the data to be read or written. |
| | | Response | The data size contained in the request is sent back. |
| Reserve | UDINT | Reserved | |

Write data

| Action | Description |
|-------------|--|
| Requirement | In order to save data to the module, the header must be prepared for communication. The data is appended directly to the header. The header and data must be specified to function block "fitWrite" as a transmit buffer. <div style="text-align: center; margin-top: 10px;"> </div> |
| Response | The module's response – the returned header – is stored in the receive buffer using function block "fitRead" and can be evaluated by the application. <div style="text-align: center; margin-top: 10px;"> </div> |

Read data

| Action | Description |
|-------------|---|
| Requirement | In order to read data from the module, the header must be prepared for communication. The header must be specified to function block "ftWrite" as a transmit buffer.  |
| Response | The module's response – the returned header and data – is stored in the receive buffer using function block "ftRead" and can be evaluated by the application.  |

Erasing a sector

| Action | Description |
|-------------|--|
| Requirement | In order to erase an area of the module's flash memory, the header must be prepared for communication. The entire 64 kB sector containing the specified address is erased. The header must be specified to function block "ftWrite" as a transmit buffer.  |
| Response | The module's response – the returned header – is stored in the receive buffer using function block "ftRead" and can be evaluated by the application.  |

9.26.13.8.4 Technology Guarding

This module is equipped with a Technology Guard. The Technology Guard integrated in the module results in the following advantages:

- USB interface not required for the Technology Guard
- Module can be used when no additional USB interfaces are available
- Module can be used when USB interfaces are prohibited for security reasons

Technology Guarding for the module is based on the same mechanism as the USB dongle connected to the CPU. The licenses themselves are verified in Automation Runtime on the target system. Automation Runtime will signal a license violation if the system has licensing requirements that are not covered by the licenses on the Technology Guard.

The Technology Guard provides the following possibilities:

- 2 tamper-resistant operating hours counters
- Possible to store multiple B&R licenses
- Customized license storage possible
- Customized data storage possible

Information:

The extended user-specific operation of the Technology Guard is handled via library "AsGuard". For more information about library "AsGuard", see Automation Help.

Information:

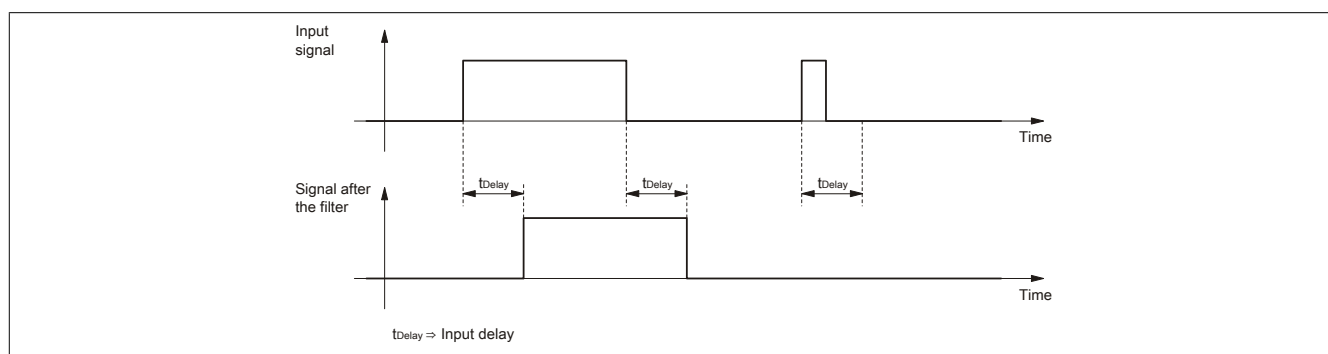

Automation Runtime C4.44 or later is required to use the functions of the Technology Guard.

9.26.13.8.5 Digital inputs

This module is equipped with 2 digital inputs. This makes it possible to use a door contact to determine whether the control cabinet door is open or closed, for example.

9.26.13.8.5.1 Input filter

An input filter is available for each input. Disturbance pulses which are shorter than the input delay are suppressed by the input filter.

The input delay can be set in steps of 100 μs . It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 μs .

| Values | Filter |
|--------|--|
| 0 | No software filter |
| 2 | 0.2 ms |
| ... | ... |
| 250 | 25 ms - Higher values are limited to this value. |

Information:

The register is described in section "Digital input filter" on page 3258.

9.26.13.8.5.2 Record input state

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

9.26.13.8.6 Analog inputs

Using 2 PT1000 temperature inputs, the control cabinet temperature can be determined at critical locations.

9.26.13.8.6.1 Filter level

The filter level determines the number of measurements for averaging. The external temperature sensors are measured every 1 ms. This means that by default, a new value (100 x 1 ms = 100 ms) with 100 measurements is available for averaging every 100 ms.

Information:

The register is described in section "[Filter level and input ramp limiting](#)" on page 3259.

9.26.13.8.6.2 Input ramp limiting

Input ramp limiting can only be performed in conjunction with filtering. Input ramp limiting is performed before filtering.

The difference of the input value change is checked for exceeding the specified limit. In the event of overshoot, the tracked input value is equal to the old value ± the limit value. The input value is monitored with the scanning grid every 1 ms.

Input ramp limiting is well suited for suppressing disturbances (spikes).

Information:

The register is described in section "[Filter level and input ramp limiting](#)" on page 3259.

9.26.13.8.6.3 Limiting the analog value

When an error state occurs, the analog value is set by default to the values listed below.

| Error state | Digital value on error |
|------------------------------|-------------------------------|
| Open circuit | 32767 (0x7FFF) |
| Upper limit value overshoot | 32767 (0x7FFF) |
| Lower limit value undershoot | -32767 (0x8001) |
| Invalid value | -32768 (0x8000) ¹⁾ |

1) After switching off the channel during operation or when the channel is disabled

9.26.13.8.6.4 Output value

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- If the input is not switched on, 0x8000 is output.

9.26.13.8.7 Blackout mode

For a description of blackout mode, see "[Blackout mode](#)" on page 3794.

9.26.13.9 Register description

9.26.13.9.1 Using this module with SGC target systems

Information:

It is not possible to use the module with SGC target systems.

9.26.13.9.2 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.26.13.9.3 Function model 0 - Standard

1) The offset specifies the position of the register within the CAN object.

9.26.13.9.4.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.13.9.4.2 CAN I/O bus controller

The module occupies 4 analog logical slots on CAN I/O.

9.26.13.9.5 Configuration

9.26.13.9.5.1 Digital input filter

Name:

CfO_DiFilter

The filter value for all digital inputs can be configured in this register.

| Data type | Values | Filter |
|-----------|--------|---|
| USINT | 0 | No software filter (bus controller default setting) |
| | 2 | 0.2 ms |
| | ... | ... |
| | 250 | 25 ms - Higher values are limited to this value. |

9.26.13.9.5.2 Filter level and input ramp limiting

Name:

CfO_AnFilter

The filter level and input ramp limiting of the input filter of the analog inputs are set in this register.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|---------------------|-------|--|
| 0 - 7 | Filter level | 0 | Filter switched off |
| | | 1 | 1 measurement |
| | | 2 | 2 measurements |
| | | 3 | 3 measurements |
| | | : | : |
| | | 100 | 100 measurements: Default |
| | | : | : |
| | | 255 | 255 measurements |
| 8 - 10 | Input ramp limiting | 000 | The input value is applied without limiting. |
| | | 001 | Limit value = 0x3FFF (16383) |
| | | 010 | Limit value = 0x1FFF (8191) |
| | | 011 | Limit value = 0x0FFF (4095) |
| | | 100 | Limit value = 0x07FF (2047) |
| | | 101 | Limit value = 0x03FF (1023) |
| | | 110 | Limit value = 0x01FF (511) |
| | | 111 | Limit value = 0x00FF (255): Default |
| 11 - 15 | Reserved | 0 | |

9.26.13.9.5.3 Enable analog input

Name:

CfO_AnEnable

These registers enable the analog inputs

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|-------------|-------|-------------|
| 0 | Channel 1 | 0 | Not enabled |
| | | 1 | Enabled |
| 1 - 7 | Reserved | 0 | |
| 8 | Channel 2 | 0 | Not enabled |
| | | 1 | Enabled |
| 9 - 15 | Reserved | 0 | |

9.26.13.9.6 Controller

9.26.13.9.6.1 Switching state of the digital output

Name:

DigitalOutput01

This register controls the digital output.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|-------|--------------|
| 0 | DigitalOutput01 | 0 | Reset output |
| | | 1 | Set output |
| 1 - 7 | Reserved | 0 | |

9.26.13.9.6.2 Reset additional information and data point histograms

Name:

ClrStatistics_OperatingData

ClrStatistics_RelHumidity

ClrStatistics_Temperature

ClrStatistics_Acceleration01 to ClrStatistics_Acceleration03

ClrStatistics_Rotation01 to ClrStatistics_Rotation03

Setting the respective bit in the register resets operating data, information and histograms. Procedure:

- Set the bit for resetting the desired data
- The bit must remain set until the registers have been reset
- As soon as the user has determined that the data has been reset, then the bit for resetting the data can be deleted
- If the bit for resetting the data is not deleted, the data will be permanently set to 0

Information:

It can take up to 1 s until the delete operation for the data is executed.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|-------|--------------|
| 0 | ClrStatistics_OperatingData Resets operating data | 0 | Do not reset |
| | | 1 | Reset |
| 1 | ClrStatistics_RelHumidity Resets information and histograms for relative humidity | 0 | Do not reset |
| | | 1 | Reset |
| 2 | ClrStatistics_Temperature Resets information and histograms for ambient temperature | 0 | Do not reset |
| | | 1 | Reset |
| 3 - 7 | Reserved | 0 | |
| 8 | ClrStatistics_Acceleration01 Resets information and histograms for Acceleration01 | 0 | Do not reset |
| | | 1 | Reset |
| 9 | ClrStatistics_Acceleration02 Resets information and histograms for Acceleration02 | 0 | Do not reset |
| | | 1 | Reset |
| 10 | ClrStatistics_Acceleration03 Resets information and histograms for Acceleration03 | 0 | Do not reset |
| | | 1 | Reset |
| 11 | ClrStatistics_Rotation01 Resets information and histograms for Rotation01 | 0 | Do not reset |
| | | 1 | Reset |
| 12 | ClrStatistics_Rotation02 Resets information and histograms for Rotation02 | 0 | Do not reset |
| | | 1 | Reset |
| 13 | ClrStatistics_Rotation03 Resets information and histograms for Rotation03 | 0 | Do not reset |
| | | 1 | Reset |
| 14 - 15 | Reserved | 0 | |

9.26.13.9.7 Communication**9.26.13.9.7.1 Status of digital inputs, digital output and I/O power supply**

Name:

DigitalInput01

DigitalInput02

StateDigitalOutput01

PowerSupply

This register is used to indicate the status of the digital inputs, the digital output and the I/O power supply voltage.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|--------|--|
| 0 | DigitalInput01 | 0 or 1 | Input state - Digital input 1 |
| 1 | DigitalInput02 | 0 or 1 | Input state - Digital input 2 |
| 2 - 3 | Reserved | - | |
| 4 | StateDigitalOutput01 | 0 or 1 | Output state digital output 1 |
| 5 - 6 | Reserved | - | |
| 7 | PowerSupply State of I/O power supply voltage | 0 | I/O power supply in the permissible range: 24 VDC -15% / +20% |
| | | 1 | I/O power supply outside the permissible range |

9.26.13.9.7.2 Module status

Name:

ModuleState01

Status register for monitoring analog inputs.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|------------------|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Range undershoot |
| | | 10 | Range overshoot |
| | | 11 | Open circuit |
| 2 - 3 | Channel 2 | 00 | No error |
| | | 01 | Range undershoot |
| | | 10 | Range overshoot |
| | | 11 | Open circuit |
| 4 - 7 | Reserved | - | |

9.26.13.9.8 Measured values**9.26.13.9.8.1 Relative humidity**

Name:
RelHumidity

An internal sensor measures the relative humidity in the area.

| Data type | Values | Information |
|-----------|----------|--------------------------------------|
| INT | 0 to 100 | Relative humidity [%], resolution 1% |

9.26.13.9.8.2 Ambient temperature

Name:
Temperature

An internal sensor measures the ambient temperature.

| Data type | Values | Information |
|-----------|--------------|--|
| INT | -250 to 1250 | Ambient temperature [°C], resolution 0.1°C |

9.26.13.9.8.3 Acceleration

Name:
Acceleration01 to Acceleration03

An internal sensor measures the acceleration.

| Data type | Values | Information |
|-----------|-----------------|---|
| INT | -32768 to 32767 | Acceleration as raw value. The conversion is to be carried out in the application: <ul style="list-style-type: none"> • 16 g = 32767 • -16 g = -32768 |

9.26.13.9.8.4 Rotation

Name:
Rotation01 to Rotation03

An internal sensor measures the rotation.

| Data type | Values | Information |
|-----------|-----------------|---|
| INT | -32768 to 32767 | Rotation as raw value. The conversion is to be carried out in the application: <ul style="list-style-type: none"> • 2000 dps = 32767 • -2000 dps = -32768 |

9.26.13.9.8.5 Analog inputs

Name:
TempExt01 to TempExt02

This register contains the analog input values. The input filter and input ramp limiting are set with register "[CfO_An-Filter](#)" on page 3259.

| Data type | Digital value | Input signal |
|-----------|---------------------------------|--|
| INT | -400 to 1250 (resolution 0.1°C) | Sensor type PT1000, Temperature measurement -40.0 to 125.0°C |

9.26.13.9.9 Additional information

Information:

The following points must be observed:

- Data recorded on the module is saved in intervals of 10 s.
- When resetting the values, it can take up to 1 s until the delete operation is executed (see register "ClrStatistics" on page 3260).

9.26.13.9.9.1 Operating data

Name:

OnTimeConnected
OnTimeDisconnected
OnTimeCombined
PowerCycles

The respective operating data is output in these registers. If needed, the values can be reset using register "ClrStatistics" on page 3260.

| Register | Data type | Values | Information |
|--------------------|-----------|--------------------|---|
| OnTimeConnected | UDINT | 0 to 4,294,967,295 | Operating time during which the module was actively connected to the network master [s], resolution 1 s |
| OnTimeDisconnected | UDINT | 0 to 4,294,967,295 | Operating time during which the module was not actively connected to the network master [s] (blackout mode), resolution 1 s |
| OnTimeCombined | UDINT | 0 to 4,294,967,295 | Total operating time of the module [s], resolution 1 s |
| PowerCycles | UDINT | 0 to 4,294,967,295 | Number of power-on cycles |

9.26.13.9.9.2 Relative humidity

Name:

RelHumidityMin
RelHumidityMax

Information about the relative humidity is output in these registers. The sampling interval is 1 s. If needed, the values can be reset using register "ClrStatistics" on page 3260.

| Register | Data type | Values | Information |
|----------------|-----------|----------|---|
| RelHumidityMin | INT | 0 to 100 | Smallest value that occurred [%], resolution 1% |
| RelHumidityMax | INT | 0 to 100 | Largest value that occurred [%], resolution 1% |

9.26.13.9.9.3 Ambient temperature

Name:

TemperatureMin
TemperatureMax

Information about the ambient temperature is output in these registers. The sampling interval is 1 s. If needed, the values can be reset using register "ClrStatistics" on page 3260.

| Register | Data type | Values | Information |
|----------------|-----------|--------------|--|
| TemperatureMin | INT | -250 to 1250 | Lowest value that occurred [°C], resolution 0.1°C |
| TemperatureMax | INT | -250 to 1250 | Highest value that occurred [°C], resolution 0.1°C |

9.26.13.9.9.4 Acceleration

Name:

Acceleration01Min to Acceleration03Min
Acceleration01Max to Acceleration03Max

Information about acceleration is output in these registers. The sampling interval is typ. 10 ms. If needed, the values can be reset using register "ClrStatistics" on page 3260.

The acceleration is provided as a raw value. The conversion is to be carried out in the application.

| Register | Data type | Values | Information |
|--|-----------|-----------------|-------------------------|
| Acceleration01Min to Acceleration03Min | INT | -32768 to 32767 | Smallest value occurred |
| Acceleration01Max to Acceleration03Max | INT | -32768 to 32767 | Largest value occurred |

9.26.13.9.9.5 Rotation

Name:

Rotation01Min to Rotation03Min

Rotation01Max to Rotation03Max

Information about rotation is output in these registers. The sampling interval is typ. 10 ms. If needed, the values can be reset using register "[ClrStatistics](#)" on page 3260.

The rotation is provided as a raw value. The conversion is to be carried out in the application.

| Register | Data type | Values | Information |
|-----------------------------------|-----------|-----------------|-------------------------|
| Rotation01Min to Rotation03Min | INT | -32768 to 32767 | Smallest value occurred |
| Rotation01Max to Rotation03Max | INT | -32768 to 32767 | Largest value occurred |

9.26.13.9.10 Data point histogram

9.26.13.9.10.1 Relative humidity

Name:

RelHumHist01Entry to RelHumHist10Entry

RelHumHist01Time to RelHumHist10Time

The relative humidity histogram data recorded on the module is displayed on these registers. If needed, the values can be reset using register "[ClrStatistics](#)" on page 3260.

| Register | Data type | Values | Information |
|--|-----------|--------------------|--|
| RelHumHist01Entry to RelHumHist10Entry | UDINT | 0 to 4,294,967,295 | Entry counter for the corresponding area |
| RelHumHist01Time to RelHumHist10Time | UDINT | 0 to 4,294,967,295 | Dwell time in corresponding area [s], resolution 1 s |

9.26.13.9.10.2 Ambient temperature

Name:

TempHist01Entry to TempHist12Entry

TempHist01Time to TempHist12Time

The ambient temperature histogram data recorded on the module is displayed on these registers. If needed, the values can be reset using register "[ClrStatistics](#)" on page 3260.

| Register | Data type | Values | Information |
|------------------------------------|-----------|--------------------|--|
| TempHist01Entry to TempHist12Entry | UDINT | 0 to 4,294,967,295 | Entry counter for the corresponding area |
| TempHist01Time to TempHist12Time | UDINT | 0 to 4,294,967,295 | Dwell time in corresponding area [s], resolution 1 s |

9.26.13.9.10.3 Acceleration

Name:

AccHist0101Entry to AccHist0108Entry

AccHist0101Time to AccHist0108Time

AccHist0201Entry to AccHist0208Entry

AccHist0201Time to AccHist0208Time

AccHist0301Entry to AccHist0308Entry

AccHist0301Time to AccHist0308Time

The acceleration histogram data recorded on the module is displayed on these registers. If needed, the values can be reset using register "[ClrStatistics](#)" on page 3260.

| Register | Data type | Values | Information |
|--------------------------------------|-----------|--------------------|--|
| AccHist0N01Entry to AccHist0N08Entry | UDINT | 0 to 4,294,967,295 | Entry counter for the corresponding area |
| AccHist0N01Time to AccHist0N08Time | UDINT | 0 to 4,294,967,295 | Dwell time in corresponding area [s], resolution 1 s |

Legend: N = 1 to 3

9.26.13.9.10.4 Rotation

Name:

RotationHist0101Entry to RotationHist0108Entry

RotationHist0101Time to RotationHist0108Time

RotationHist0201Entry to RotationHist0208Entry

RotationHist0201Time to RotationHist0208Time

RotationHist0301Entry to RotationHist0308Entry

RotationHist0301Time to RotationHist0308Time

The rotation histogram data recorded on the module is displayed on these registers. If needed, the values can be reset using register "[ClrStatistics](#)" on page 3260.

| Register | Data type | Values | Information |
|--|-----------|--------------------|--|
| RotationHist0N01Entry to RotationHist0N08Entry | UDINT | 0 to 4,294,967,295 | Entry counter for the corresponding area |
| RotationHist0N01Time to RotationHist0N08Time | UDINT | 0 to 4,294,967,295 | Dwell time in corresponding area [s], resolution 1 s |

Legend: N = 1 to 3

9.26.13.9.11 Flatstream communication

For a description of Flatstream communication, see ["Flatstream communication" on page 3802](#)

9.26.13.9.12 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|--------------------|-------------|
| | 200 μ s |

9.26.13.9.13 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|-------------------------------------|---|
| Temperature and relative humidity | 1 s |
| Acceleration and rotation | Typ. 10 ms |
| Digital inputs | 100 μ s without filtering 200 μ s with filtering |
| Digital output | Equal to the minimum cycle time |
| Analog inputs | 1 ms |
| State of I/O power supply voltage | <10 ms |
| User flash Flatstream communication | <10 ms |

9.26.14 X20DS4387

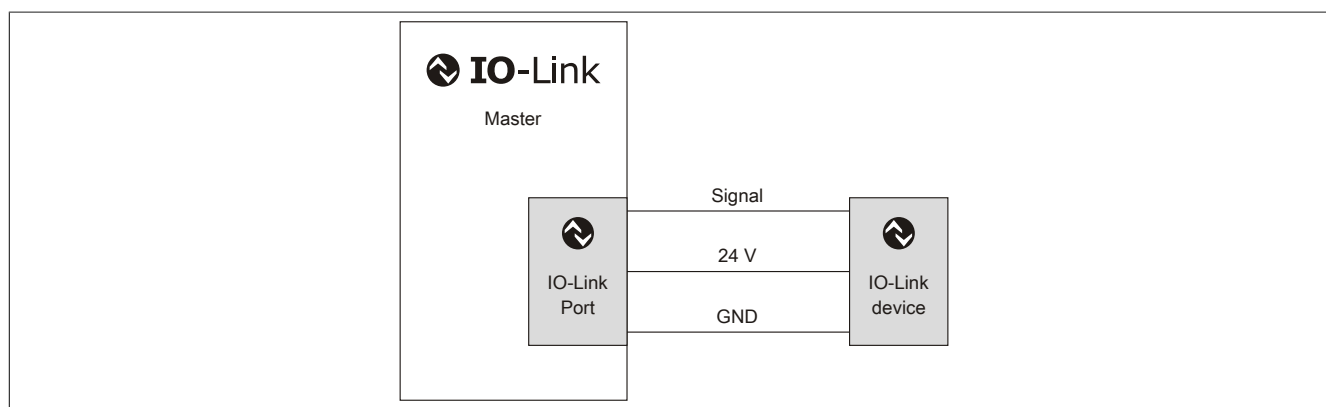

Data sheet version: 3.04

9.26.14.1 General information

IO-Link is a standardized communication system for connecting intelligent sensors and actuators in an automation system. The standardization includes electrical connection data as well as a digital communication protocol, which is used by the sensors and actuators in the automation system for data exchange.

An IO-Link system consists of an IO-Link master and one or more IO-Link devices, i.e. sensors and actuators. The IO-Link master makes the interface available for higher level control and controls communication with the connected IO-Link devices.

An IO-Link device is an intelligent sensor or actuator. With regard to IO-Link, "intelligent" means that a device possesses a series number or parameter data (sensitivity, switching delays or characteristic curves), which can be written to or read via the IO-Link protocol.

Process optimization

The use of intelligent sensors and actuators contributes to process optimization. Process optimization means that downtimes should be kept as short as possible. These consist mainly of standstills due to errors and setup times.

Integrated communication down to the IO-Link devices offers many advantages in error diagnostics. Errors are detected much faster than before. If a sensor or actuator must be replaced, lengthy configuration work is no longer necessary after the change thanks to a potentiometer, or a configuration tool and laptop. After changing the sensor/actuator, the parameters are automatically transferred to the sensor.

This parameter download is not only beneficial when errors occur. It can also be used for changing parameters when a load change is performed. This shortens setup times, making product changes and small batches more economical.

Integration of IO-Link in X20 System

IO-Link is integrated in the X20 system using this digital module. All 4 channels are IO-Link interfaces, but can also be used as standard inputs or outputs. The specified 3-wire connections can be ideally implemented thanks to the X20 connector system with 12 terminal points per module. All specified transfer rates are also supported.

POWERLINK integration

IO-Link doesn't stop at the I/O module. It must be integrated in the higher-level bus system to fully utilize the benefits. When using POWERLINK, access is made possible via device description files in XML format.

- 4 IO-Link interfaces per module
- Each interface can be configured as a standard input or output
- Seamless integration in POWERLINK
- Supports all transfer rates

9.26.14.2 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | Other functions |  |
| X20DS4387 | X20 digital signal module, 4x IO-Link master, 4 digital channels configurable as inputs or outputs, 3-wire connections | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |
| | | |
| | | |

Table 562: X20DS4387 - Technical data

9.26.14.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

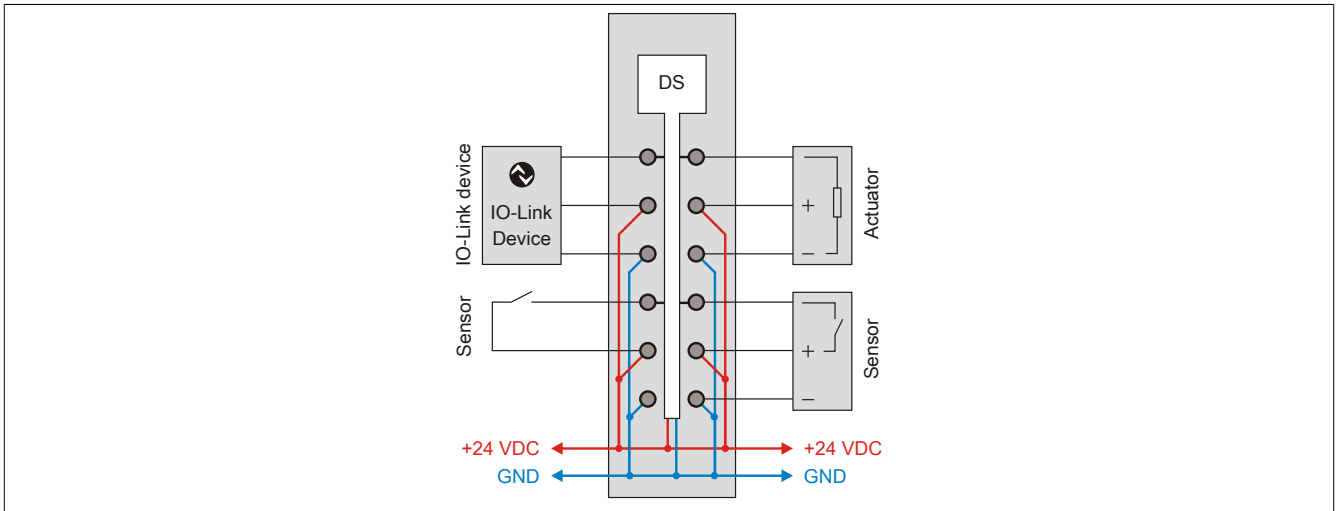

| Figure | LED | Color | Status | Description |
|---|---------|-----------|--------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | Warning / error for an IO-Link interface |
| | C1 - C4 | Green/Red | Off | Interface in SIO mode |
| | | | Green | Interface in IO-Link mode |
| | | | Red | Output overloaded (short circuit, temperature) |
| | Q1 - Q4 | Orange | | Input/output status of the corresponding IO-Link interface |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.26.14.8 Register description

9.26.14.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.26.14.8.2 Function model 0 - default

| Register | Name | Data type | Read | | Write | |
|------------------------------|--|-----------|-----------------|---------|-----------------|---------|

1) The offset specifies the position of the register within the CAN object.

9.26.14.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "Using I/O modules on the bus controller" on page 3789.

9.26.14.8.3.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.26.14.8.4 Limitations

The I/O module offers extensive function and configuration options. Many of these options require cycle data. The amount of cycle data required depends on the following parameters:

- Number of interfaces in use
- Use of events
- Runtime configuration in the cycle data

Take note that the amount of cycle data available for each I/O module used in the system is limited:

| | |
|-------------------------|----------|
| Sum of the input data: | 29 bytes |
| Sum of the output data: | 30 bytes |

Runtime configuration and events

Each I/O module requires the following amounts of cycle data for runtime configuration and events, if enabled:

| Activated function | Input | Output |
|---|-------|--------|
| Runtime configuration in the cycle data | 6 | 10 |
| Events | 4 | 1 |

Interface data

The following amounts of cyclic data are required for each interface being used:

| Functionality | Operating state | | | | | | | |
|--------------------|-----------------------|-----------------------|----------|--------|-----------|--------|----------|--------|
| | OPERATE | | DIGINPUT | | DIGOUTPUT | | INACTIVE | |
| | Input | Output | Input | Output | Input | Output | Input | Output |
| Payload | 0 to 27 ¹⁾ | 0 to 30 ¹⁾ | 1 | - | - | 1 | - | - |
| Status information | 2 | - | 2 | - | 2 | - | - | - |

1) User configurable

9.26.14.8.5 Interface operation

9.26.14.8.5.1 Communication mode

Name:

Control01 to Control04

Writing to this register defines the desired state of the IO-Link device. This register can be used to define if the IO-Link device should be operated in "normal" communication mode (OPERATE), as a digital input (DIGINPUT) or as a digital output (DIGOUTPUT).

Switching to SIO mode can make sense for IO-Link devices that only transfer digital information anyway (e.g. light curtains) but after the basic configuration should be faster than is possible in "normal" communication mode. A parameter configuration for the object directory can also be made in SIO mode.

To deactivate an interface, INACTIV should be used.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 10 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------|-------|--|
| 0 - 3 | Communication mode | 0 | INACTIV |
| | | 1 | DIGINPUT |
| | | 2 | DIGOUTPUT |
| | | 10 | OPERATE (bus controller default setting) |
| 4 - 7 | Reserved | - | |

9.26.14.8.5.2 Operating state

Name:

StatusEvents01 to StatusEvents04

This register contains the actual status of communication between the module and IO-Link device. Additionally, the number of events read by the IO-Link device are also counted in this register.

| Data type | Values |
|---------------------|------------------------|
| USINT ¹⁾ | See the bit structure. |
| UINT | |

1) In the bus controller or standard function model, of communication mode = INACTIV

Bit structure:

| Bit | Description | Value | Information |
|-------------|--|-------|-----------------|
| 0 - 3 | State of the IO-Link device | x | See table below |
| 4 - 7 or 15 | Event counter from the respective IO-Link device | x | |

State of the IO-Link device

| Value | Abbreviation | Description |
|-------|----------------|---|
| 0 | INACTIVE | Interface is inactive: No communication and signal output or input. This state is not changed automatically. |
| 1 | DIGINPUT | SIO input mode: The interface behaves like a digital input. |
| 2 | DIGOUTPUT | SIO output mode: The interface behaves like a digital output. |
| 4 | ESTABLISHCOMM | Establishing connection to IO-Link device. This state remains as long as a device is not found. |
| 5 | INITMASTER | Consecutive states experienced during startup and configuration of an IO-Link device. |
| 6 | INITDEVICE | |
| 7 | INITOPERATE | |
| 8 | PREOPERATE | |
| 9 | READYTOOPERATE | Waiting for valid data from the IO-Link device. This state can follow the OPERATE state if the device reports during operation that it cannot send any more valid data. |
| 10 | OPERATE | Communication with the IO-Link device via serial protocol. Valid data is exchanged. |
| 11 | COMSTOP | The IO-Link interface is reinitialized. The ESTABLISHCOMM state follows this state. |
| 12 | FALLBACK | For switching to SIO mode |
| 13 | STARTUP | IO-Link device restart |
| 14 | SIO | Switching to SIO mode |

States with a gray background are applied continuously, all others are intermediate states. An exception is state ESTABLISHCOMM (4): This state is permanently assumed if no device is connected.

Dynamic values from the IO-Link device make up the input data for an IO-Link interface if one of the states DIGINPUT, DIGOUTPUT or OPERATE has been reached. These states can also be exited when errors occur. The device is restarted if a fatal error occurs, which means the state reverts back to ESTABLISHCOMM. Another possibility is that there is no new data being read from the device in the OPERATE state. In this case, the state changes to READYTOOPERATE and waits for new data.

During the first startup, the module sends the value 0 for the inputs of an IO-Link interface. If the states DIGINPUT, DIGOUTPUT or OPERATE are exited, then the inputs are frozen at the most recently read value until valid data is able to be read from the device again.

9.26.14.8.5.3 Length of the I/O cycle

Name:

CycleLength01 to CycleLength04

The value in this register specifies how many X2X cycles are required on the respective interface for a the IO-Link process data to be completely updated.

The module automatically selects the best possible IO-Link cycle time per interface for the connected IO-Link device. This is always a multiple of the X2X cycle time. The cycle times of the 4 IO-Link interfaces are independent of one another.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.14.8.5.4 Reading

Name:

DeviceID01 to DeviceID04

This register contains the IO-Link device ID assigned by the manufacturer. The device ID can be read for every IO-Link interface.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.14.8.5.5 Function ID

Name:

FunctionID01 to FunctionID04

This register contains the IO-Link function ID assigned by the manufacturer. The function ID can be read for every IO-Link interface.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.14.8.5.6 IO-Link vendor ID

Name:

VendorID01 to VendorID04

This register contains the IO-Link vendor ID. The ID can be read for every IO-Link interface.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.14.8.5.7 Cyclic input data

Name:

DataIn01_01 to DataIn01_27 (bus controller function model: up to xx01_04)

...

DataIn04_01 to DataIn04_27 (bus controller function model: up to xx04_04)

This register contains the cyclic input data for the respective interface.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.26.14.8.5.8 Cyclic output data

Name:

DataOut01_01 to DataOut01_30 (bus controller function model: up to xx01_04)

...

DataOut04_01 to DataOut04_30 (bus controller function model: up to xx04_04)

This register contains the cyclic output data for the respective interface.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.26.14.8.6 SIO mode

The IO-Link interface can be used like a digital input or output in SIO mode. To activate the SIO mode, the operating state must be set in the "Control0x" on page 3275 register to DIGINPUT or DIGOUTPUT. Runtime configuration is not possible during operation in SIO mode, however the boot configuration can be used.

9.26.14.8.6.1 Digital input filter

Name:

ChInputFilter01 to ChInputFilter04

When operated as a digital input, a filter time can be configured in this register. Valid values for the filter time are 0 and 2 to 250. Value 0 disables the filter. Other values specify the filter time as a multiple of 0.1 ms.

| Data type | Values | Filter |
|-----------|--------|--|
| USINT | 0 | No software filter |
| | 2 | 0.2 ms |
| | ... | ... |
| | 10 | 1 ms (bus controller default setting) |
| | ... | ... |
| | 250 | 25 ms - Higher values are limited to this value. |

9.26.14.8.6.2 Digital inputs

Name:

DigitalInput01 to DigitalInput04

These registers display the input states of the digital inputs individually for each channel.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

| Bit | Name | Value | Information |
|-------|----------------|--------|-------------------------------|
| 0 | DigitalInput0x | 0 or 1 | Input state - Digital input x |
| 1 - 7 | Reserved | - | |

9.26.14.8.6.3 Digital outputs

Name:

DigitalOutput01 to DigitalOutput04

These registers display the output states of the digital outputs individually for each channel.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

| Bit | Name | Value | Information |
|-------|-----------------|-------|------------------------|
| 0 | DigitalOutput0x | 0 | Digital output x reset |
| | | 1 | Digital output x set |
| 1 - 7 | Reserved | - | |

9.26.14.8.7 Parameter

IO-Link devices can provide user parameters. There are two ways to access these parameters:

- "Boot configuration" on page 3279
- "Runtime configuration" on page 3279

9.26.14.8.7.1 Boot configuration

The values specified by the user are transferred during the boot procedure (or when the IO-Link device is connected).

Up to 32 parameter values can be specified for each IO-Link interface. 1, 2, and 4 byte parameters are supported.

The boot configuration can be used in the operating states OPERATE, DIGINPUT and DIGOUTPUT.

The following specifications are necessary for parameters that should be set during the boot procedure:

| Name | Range of values | Description |
|----------|--------------------|---|
| Index | 0 to 65535 | Parameter index according to device manufacturer's specifications |
| Subindex | 0 to 255 | Parameter sub index according to device manufacturer's specifications |
| Length | 1, 2, 4 | Length of data in bytes |
| Data | 0 to 4,294,967,295 | Data to be written. Only low-order bytes are used for 1 or 2 byte parameters. |

9.26.14.8.7.2 Runtime configuration

The runtime configuration can also be made after the IO-Link device has booted up. Parameters can be read or written.

The runtime configuration can take place in the cyclic data or through acyclic communication (function blocks AsIOAccRd and AsIOAccWr).

Runtime configuration is available for interfaces in the OPERATE state.

The following specifications are necessary for accessing parameters:

| Name | Range of values | Description |
|-----------------|-----------------|--|
| Interface | 0, 1, 2, 3 | Addressed interface of the module |
| Sequence number | 0 to 15 | A change to this value indicates a new task. The sequence number is set identically to the value of the request in the response message. |
| Index | 0 to 65535 | Parameter index according to device manufacturer's specifications. |
| Subindex | 0 to 255 | Parameter sub index according to device manufacturer's specifications. |
| Length | 0 to 228 (229) | Length of data in bytes. Up to 228 bytes are supported for write access and 229 bytes for read access. The length does not have to be specified when requesting a read access (the device reports the length of the read data). |
| Data | | IO-Link supports up to 228 (229) bytes of data each time a parameter is accessed. The length is limited to 1, 2 or 4 bytes in the cyclic data with boot configuration and runtime configuration. The full data range can be used with acyclic runtime configuration (AsIOAcc Library). |
| Read/write | 0, 1 | For the request to the IO-Link device. 0 → read 1 → write |
| Errors | 0, 1 | Defined in the response from the IO-Link device. 0 → No error occurred 1 → Error When an error occurs, the first two bytes of data are contained in the error code (the reported length is 2). |
| Sequence number | 0 to 15 | |

Access to an IO-Link device's parameters occurs via a request and subsequent response from the device.

A new request is detected due to a changed sequence number. Therefore, the sequence number must be the last data item that is written.

The response contains the sequence number of the request.

The length is not relevant for a read request. It is automatically determined by the IO-Link device and reported in the response message.

If an error occurs (e.g. due to accessing an index or sub index that does not exist), this is signaled by a set error bit in the response. The error response always has a length of 2. These 2 bytes contain the manufacturer-specific error code.

9.26.14.8.8 Object directory access

Writing to the corresponding registers "[ParameterCmdOut](#)" on page 3282 and "[ParameterCtrlOut](#)" on page 3281 defines and sends an order for reading or writing an IO-Link object.

Procedure for sending an order

- Define register "[ParameterCmdOut](#)" on page 3282 by entering the length, index and subindex
- During write access, write the required parameter data that is to be stored in the object directory to registers "[ParameterDataOut_XX](#)" on page 3282.
- Define register "[ParameterCtrlOut](#)" on page 3281 by entering the interface number, read/write ID and the incremental sequence number. Additionally, an error bit can be configured during read access.

The module detects when the sequence number changes and accepts the order. Communication with the IO-Link device takes place.

When evaluating read/write access, the following is available from the register "[ParameterCtrlIn](#)" on page 3281:

- Access sequence number
- Access interface number
- Type of access
- Payload length for read access to values smaller than 15 bytes
- Read access error bit

When evaluating read/write access, the following is available from the register "[ParameterCmdIn](#)" on page 3281:

- Payload length for read access
- Access index and subindex

When evaluating read access, the following is available from the register "[ParameterDataIn_XX](#)" on page 3282:

- Values read/written

During write access, the sequence number in register "[ParameterCtrlIn](#)" on page 3281 is only set to the written value when processing the order has been completed and the parameter data has been read from the object directory for the IO-Link device and entered in the registers "[ParameterDataIn_XX](#)" on page 3282.

A response provided by increasing the sequence number must be guaranteed (a timeout may be necessary for this purpose). That means, if the written sequence number from register "[ParameterCtrlOut](#)" on page 3281 is accepted by register "[ParameterCtrlIn](#)" on page 3281, then the application can safely assume that access has taken place.

Limit values for write/read access

- Index: 0 to 65535
- Subindex: 0 to 255
- Data length: 1 to 228 bytes for write access
- Data length: 1 to 229 bytes for read access

The resulting changes are written once to the IO-Link device without being temporarily saved on the module. That means, after disconnecting the IO-Link device, the values from the ODW registers are written back to the IO-Link device (see register "[ODW_Data_XX](#)" on page 3282).

9.26.14.8.8.1 Response to read/write access

Name:

ParameterCtrlIn

This register contains the response for dynamic read/write access of the object directory.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|-------------------------------------|--------------|-----------------|
| 0 - 3 | Sequence number | x | |
| 4 - 7 | Interface number | 00 | Interface 1 |
| | | 01 | Interface 2 |
| | | 10 | Interface 3 |
| | | 11 | Interface 4 |
| 8 - 11 | Payload data length | 0000 to 1111 | Number of bytes |
| 12 - 13 | Reserved | - | |
| 14 | Read / write | 0 | Read access |
| | | 1 | Write access |
| 15 | Errors | 0 | No error |
| | | 1 | Errors |

Payload data length

The payload data length of the parameter access is copied by the module from the register "[ParameterCmdIn](#)" on [page 3281](#) (bit 24 to 27). Because this is a 4-bit value, the specification of the payload length is possible for a value with a maximum of 15 bytes. In the event that parameter sets larger than 15 bytes are accessed, the information about the number of bytes read during the parameter access must be taken from "[ParameterCmdIn](#)".

9.26.14.8.8.2 Configuration of dynamic read/write access

Name:

ParameterCtrlOut

This register is used to configure dynamic read/write access of the object directory.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|--|
| 0 - 3 | Sequence number | x | |
| 4 - 7 | Interface number | 00 | Interface 1 (bus controller default setting) |
| | | 01 | Interface 2 |
| | | 10 | Interface 3 |
| | | 11 | Interface 4 |
| 8 - 13 | Reserved | - | |
| 14 | Read / write | 0 | Read access (bus controller default setting) |
| | | 1 | Write access |
| 15 | Error response (only defined for read access, this bit should be set to "0" for write access) | 0 | Inactive (bus controller default setting) |
| | | 1 | Active |

9.26.14.8.8.3 Feedback from I/O object information

Name:

ParameterCmdIn

This register returns the number of bytes read during a read access.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|----------------------------|-------|-------------|
| 0 - 15 | Object index being used | x | |
| 16 - 23 | Object subindex being used | x | |
| 24 - 31 | Number of bytes read | x | |

9.26.14.8.8.4 Configuration of the I/O object information

Name:

ParameterCmdOut

This register is used to configure dynamic read/write access of the object directory.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UDINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|-------------------------|------------|-----------------------------------|
| 0 - 15 | Object index | 0 to 65535 | Bus controller default setting: 0 |
| 16 - 23 | Object subindex | 0 to 255 | Bus controller default setting: 0 |
| 24 - 31 | Payload length in bytes | 0 to 255 | Bus controller default setting: 0 |

9.26.14.8.8.5 Runtime parameter data read

Name:

ParameterDataIn_0 to ParameterDataIn_57

The corresponding parameter data is written to this register during read access of the object directory for the IO-Link device.

The length specified in register "ParameterCmdOut" determines how many 4-byte registers are read from the object directory for the IO-Link device and how many in the last byte are still valid.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.14.8.8.6 Runtime parameter data written

Name:

ParameterDataOut_0 to ParameterDataOut_57

The parameter data from this register is written during write access of the object directory for the IO-Link device.

The length specified in register "ParameterCmdOut" on page 3282 determines how many 4-byte registers are written to the object directory for the IO-Link device and how many in the last byte are still valid.

| Data type | Values | Information |
|-----------|--------------------|-----------------------------------|
| UDINT | 0 to 4,294,967,295 | Bus controller default setting: 0 |

9.26.14.8.8.7 Boot parameter data

Name:

ODW_Data_0 to ODW_Data_127

This register contains parameter data for configuration of the IO-Link device.

| Data type | Values | Information |
|-----------|--------------------|-----------------------------------|
| UDINT | 0 to 4,294,967,295 | Bus controller default setting: 0 |

9.26.14.8.8.8 Boot I/O object information

Name:

ODW_Target_0 to ODW_Target_127

A write procedure on this register will transfer the parameter information from the corresponding "ODW_Data" on [page 3282](#) register to the IO-Link device.

Example:

If the ODW_Target_0 register is written to, the parameter data from ODW_Data_0 is applied by the module and transferred to the object dictionary of the IO-Link device.

Unlike short-term access, the values are also stored in RAM on the module in order to be able to reload these parameters in the object directory for the IO-Link device when restarting the IO-Link device.

Information:

"ODW_Data" must be defined before "ODW_Target".

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UDINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|------------------|-------|--|
| 0 - 15 | Object index | x | |
| 16 - 23 | Subindex | x | |
| 24 - 27 | Interface number | 00 | Interface 1 (bus controller default setting) |
| | | 01 | Interface 2 |
| | | 10 | Interface 3 |
| | | 11 | Interface 4 |
| 28 - 30 | Length in bytes | x | |

9.26.14.8.9 Errors and warnings

Name:

ErrorsWarnings01 to ErrorsWarnings04

The counter is increased by one if the IO-Link device reports an error or warning.

An error is a fatal event if it causes an IO-Link device to lose its intended functionality. An error causes the IO-Link device to leave the OPERATE state (see ["Operating state" on page 3276](#)) and re-initialize.

The cause of a warning could be one-time communication disturbances. Warnings are events that deviate from normal operating behavior but do not necessarily result in loss of functionality. Several consecutively occurring warnings can result in an error.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|-------|---|
| 0 - 3 | Warning counter | x | Counts the errors that do not immediately lead to ending the communication with the IO-Link device |
| 4-7 | Error counter | x | Counts the errors that causes the IO-Link device to change from status "10 = cyclic data exchange" and be reinitialized |

9.26.14.8.10 Event handling

If an event occurs on an IO-Link device, then the device retrieves it and stores the data in the following registers:

| Register | Description |
|----------------------------------|--|
| "EventPortSeq" on page 3285 | IO-Link device interface that triggered the event. Sequence number, incremented with each event |
| "Event description" on page 3284 | Event description: Instance, type and mode |
| "Event code" on page 3284 | Event code |

The sequence number for the event counter is incremented by 1 with each event in order to notify the application. After the application has read the event data, the module has to use the "EventQuit" on page 3285 register to signal that the values were retrieved from registers "EventQualifier" and "EventCode" and then the module can read the next event from IO-Link device. The value in register "EventPortSeq" is considered a correct acknowledgment value.

Events are available for interfaces in the OPERATE state. An event inhibit can also be set in Automation Studio. This is specified as a number of X2X Link cycles for an event before it can be overwritten by the next event. Events that occur during the inhibit time are cached on the module.

9.26.14.8.10.1 Event code

Name:

EventCode

This register is used to indicate the manufacturer-specific code for the IO-Link device.

In addition to manufacturer-specific codes, there are also the event codes specified for IO-Link in case the IO-Link device does not provide an EventCode.

| Data type | Value | Information |
|-----------|----------------|---------------------------------------|
| UINT | 0 to 65535 | Event code |
| | 0x34 / 0xFFFF0 | Invalid event from the IO-Link device |
| | 0x54 / 0xFF80 | IO-Link device message |
| | 0x74 / 0xFF80 | IO-Link device error |
| | 0x74 / 0x6320 | Parameter error |
| | 0x70 / 0xFF10 | Communication error |

9.26.14.8.10.2 Event description

Name:

EventQualifier

IO-Link devices can generate events (including manufacturer-specific events). Information about the instance, type and mode of the event can be read from this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------------------------------|------------|--|
| 0 - 2 | Instance layer generated by the event | 000 | Unknown |
| | | 001 | Hardware |
| | | 010 | Data exchange layer for the IO-Link device |
| | | 011 | Application layer for the IO-Link device |
| | | 100 | Application |
| | | 101 to 111 | Reserved |
| 3 | Reserved | - | |
| 4 - 5 | Type of event | 00 | Reserved |
| | | 01 | Information |
| | | 10 | Warning |
| | | 11 | Errors |
| 6 - 7 | Mode of the event | 00 | Reserved |
| | | 01 | One-time event |
| | | 10 | Pending event is gone |
| | | 11 | Pending event |

9.26.14.8.10.3 Event interface

Name:

EventPortSeq

IO-Link devices can generate events (including manufacturer-specific events). Information about the interface that caused the event can be read from this register. By reading the sequence number, the application can determine if a new event has occurred. For this topic, see also ["Event handling" on page 3284](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------|---------|--|
| 0 - 3 | Interface | 0 | Interface 1 |
| | | 1 | Interface 2 |
| | | 2 | Interface 3 |
| | | 3 | Interface 4 |
| | | 4 - 7 | Reserved |
| 4 - 7 | Event counter | 0 to 15 | Sequence number is incremented with each new event that occurs |

9.26.14.8.10.4 Acknowledge events

Name:

EventQuit

Register for acknowledging events so that the module can retrieve the next event. The event that has been read must be acknowledged with the value from register ["EventPortSeq" on page 3285](#).

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.26.14.8.11 IO-Link cycle time

The I/O module automatically selects the best possible IO-Link cycle time per interface for the connected IO-Link device. This is always a multiple of the X2X cycle time. The cycle times of the 4 IO-Link interfaces are independent of one another. The module can read back which cycle time was selected for an IO-Link interface.

The minimum cycle time is 2.3 ms.

9.26.15 X20(c)DS438A

Data sheet version: 1.52

9.26.15.1 General information

The module is an IO-Link master that allows intelligent sensors and actuators to be connected to the X20 system in accordance with the IO-Link standard. The module can be used to operate up to 4 IO-Link devices. All IO-Link channels can be used either as standard digital inputs or outputs.

- 4 IO-Link devices
- 4 digital channels, can be configured as input or output
- 24 VDC and GND for sensor/actuator supply
- NetTime timestamps: IO-Link data

NetTime timestamps for IO-Link

Using these timestamps, applications can record value changes at on the IO-Link network and trigger events that have a higher resolution than the I/O cycle would allow.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise time, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

Conversely, the CPU can predefine output events, apply a timestamp and transfer them to the module. The module then executes the predefined action at the precise time defined by the CPU.

9.26.15.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.26.15.3 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | Other functions | |
| X20DS438A | X20 digital signal module, 4x IO-Link master V1.1, 4 digital channels configurable as inputs or outputs, 3-wire connections, NetTime function |  |
| X20cDS438A | X20 digital signal module, coated, 4x IO-Link master V1.1, 4 digital channels configurable as inputs or outputs, 3-wire connections, NetTime function | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |
| X20cBM11 | X20 bus module, coated, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |

Table 563: X20DS438A, X20cDS438A - Order data

Optional accessories for sensors

Connectors and cables from the X67 system accessories can be used to connect standard IO-Link sensors and devices.

Sensors/Devices with M12 connector

| M12 connector | |
|---------------|--|
| X67AC0C21 | X67 female M12 connector, 5-pin, A-keyed, shielded, cage clamp connection |
| X67AC2C21 | X67 female M12 connector, 5-pin, A-keyed, shielded, screw clamp connection |

Sensors/Devices with M8 connector

| M8 connector | |
|---|---|
| X67AC0P20 | Female M8 connector, 4-pin, piercing connection |
| M8 connector with cable, open on one side | |
| X67CA0P20.xxxx | M8 attachment cable, 4-pin, straight |
| X67CA0P30.xxxx | M8 attachment cable, 4-pin, angled |

9.26.15.4 Technical data

| Model number | X20DS438A | X20cDS438A |
|---|---|------------|
| Short description | | |
| I/O module | IO-Link master with 4 IO-Link interfaces | |
| General information | | |
| B&R ID code | 0xCAC0 | 0xEB57 |
| Status indicators | IO-Link, operating state, module status | |
| Diagnostics | | |
| Module run/error | Yes, using status LED and software | |
| IO-Link operating state | Yes, using status LED and software | |
| C/Q status | Yes, using status LED and software | |
| Cable specification | | |
| Cable type | 3-pin standard sensor cable, unshielded | |
| Cable length | Max. 20 m | |
| Line capacitance | Max. 3 nF | |
| Loop resistance | Max. 6 Ω | |
| Power consumption | | |
| Bus | 0.01 W | |
| Internal I/O | 0.71 W | |
| Additional power dissipation caused by actuators (resistive) [W] | - | |
| Certifications | | |
| CE | Yes | |
| EAC | Yes | |

| Sensor/Actuator power supply | | |
| Voltage | I/O power supply minus voltage drop for short circuit protection | |
| Voltage drop for short-circuit protection at 0.5 A | Max. 0.3 V | |
| Power consumption | Max. 12 W per IO-Link interface | |
| Short-circuit proof | Yes | |
| Overload protection | | |
| Switch-off delay | Configurable using software | |
| Switch-off duration | Configurable using software | |
| IO-Link in master mode | | |
| Transfer rates | | |
| COM1 | 4.8 kbaud | |
| COM2 | 38.4 kbaud | |
| COM3 | 230.4 kbaud | |
| Limit values for COM3 | | |
| Max. connection capacity | 22 nF (cable + IO-Link device) | |
| Max. load | 96 Ω / 250 mA | |
| Data format | 1 start bit, 8 data bits, 1 parity bit (even), 1 stop bit | |
| Bus level | 24 VDC (active), 0 VDC (resting voltage) | |
| IO-Link in master mode or in SIO mode "digital output" | | |
| Variant | Bipolar, positive and negative switching | |
| Peak short-circuit current | <1.3 A | |
| Residual voltage | <0.7 VDC at nominal current 0.25 A | |
| Switching voltage | I/O power supply minus voltage drop for short circuit protection and semiconductor switch | |
| Voltage drop on semiconductor switch | Max. 0.5 VDC at 0.25 A | |
| Switching frequency | Typ. 25 kHz 300 kHz in IO-Link master mode | |
| Switching delay | | |
| 0 → 1 | <10 μs | |
| 1 → 0 | <10 μs | |
| Switch-on in the event of overload shutdown or short-circuit shutdown | Configurable with software | |
| Isolation voltage between IO-Link and bus | 500 V _{Eff} | |
| IO-Link in SIO mode "digital output" | | |
| Nominal voltage | 24 VDC | |
| Nominal output current | 0.25 A | |
| Total nominal current | Max. 1 A | |
| Output circuit | Sink or source | |
| Switching frequency (resistive load) | Max. 500 Hz | |
| Output protection ¹⁾ | Thermal cutoff if overcurrent or short circuit occurs, integrated protection for switching inductances | |
| IO-Link in SIO mode "digital input" | | |
| Nominal voltage | 24 VDC | |

Table 564: X20DS438A, X20cDS438A - Technical data

| Model number | X20DS438A | X20cDS438A |
|---|--|---|
| Input characteristics per EN 61131-2 | Type 1 | |
| Input filter | | |
| Hardware | 300 ns | |
| Software | - | |
| Input circuit | Sink | |
| Input voltage | 24 VDC -15% / +20% | |
| Input current at 24 VDC | Typ. 4 mA | |
| Input resistance | Typ. 6 kΩ | |
| Switching threshold | | |
| Low | <5 VDC | |
| High | >15 VDC | |
| Isolation voltage between IO-Link and bus | 500 V _{Eff} | |
| Electrical properties | | |
| Electrical isolation | Bus isolated from IO-Link IO-Link not isolated from IO-Link | |
| Operating conditions | | |
| Mounting orientation | | |
| Horizontal | Yes | |
| Vertical | Yes | |
| Installation elevation above sea level | | |
| 0 to 2000 m | No limitations | |
| >2000 m | Reduction of ambient temperature by 0.5°C per 100 m | |
| Degree of protection per EN 60529 | IP20 | |
| Ambient conditions | | |
| Temperature | | |
| Operation | | |

Table 564: X20DS438A, X20cDS438A - Technical data

1) Interrupting current during overload: Between 0.3 A and 0.8 A.

9.26.15.5 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

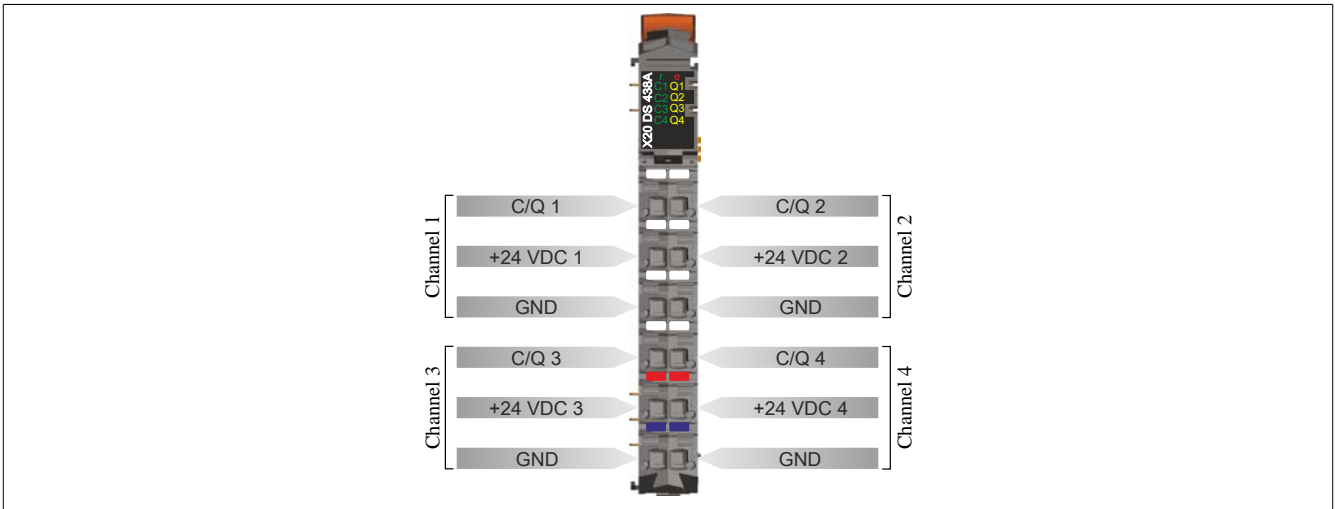

| Figure | LED | Color | Status | Description |
|---|---------|-----------|--------------|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | Mode BOOT (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | OPERATE mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Double flash | One of the following errors has occurred: |
| | C1 - C4 | Red | On | Overload on the supply or on the channel's C/Q line |
| | | | Off | Interface in SIO mode |
| | | Green/Red | Single flash | Channel in OPERATE mode, no IO-Link communication |
| | | | Double flash | Channel in OPERATE mode, error on inspection level |
| | Q1 - Q4 | Green | On | Channel in OPERATE mode, IO-Link communication active |
| | | | Orange | Input/output state of corresponding IO-Link interface |

1) Depending on the configuration, a firmware update can take up to several minutes.

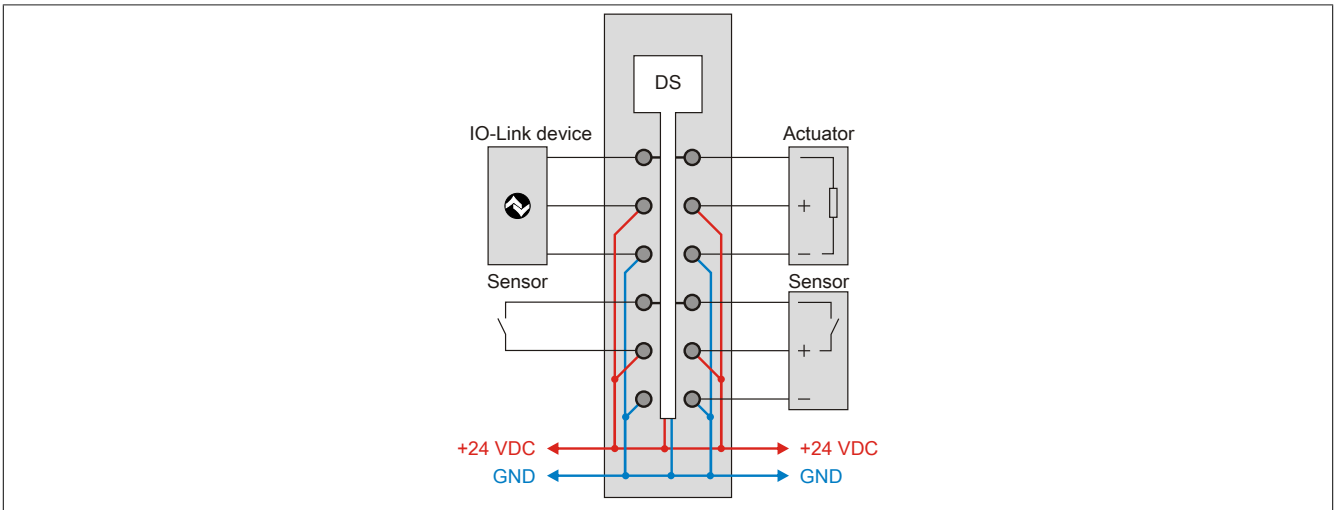

Blink times of LEDs C1 through C4 for single and double flash.

| | |
|--------------|---|
| Single flash |  |
| Double flash |  |
| | 1 second |

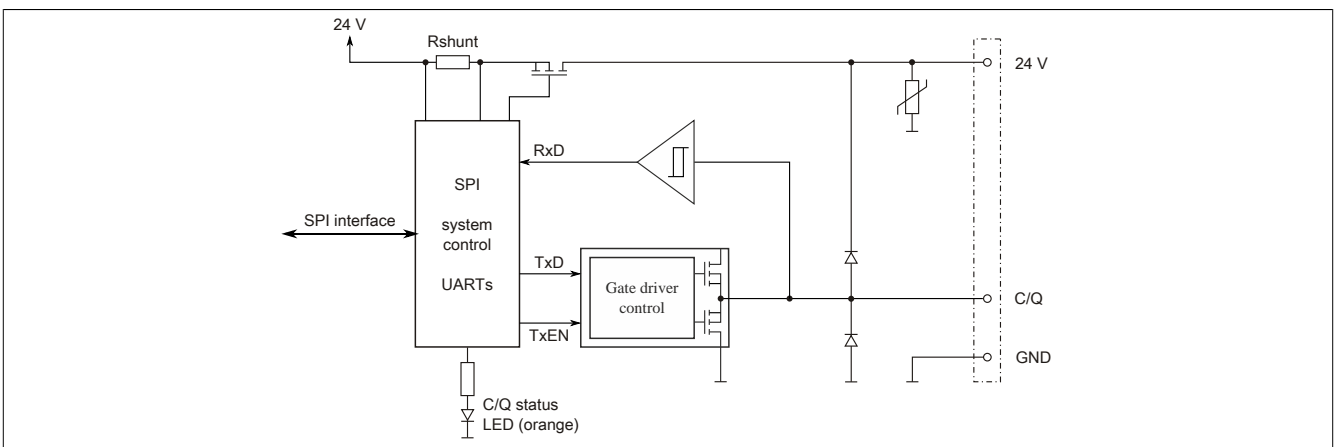

9.26.15.6 Pinout

9.26.15.7 Connection example

9.26.15.8 Input/output circuit diagram

9.26.15.9 SG3 support

This module does not support SG3 target systems.

9.26.15.10 Register description

9.26.15.10.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.26.15.10.2 Function model 0 - Standard

1) The offset specifies the position of the register within the CAN object.

9.26.15.10.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.15.10.3.2 CAN I/O bus controller

The module occupies 3 analog logical slots with CAN I/O.

9.26.15.10.4 Module configuration

The module can be used to connect IO-Link devices (IO-Link version 1.1). The power supply of 24 VDC for the IO-Link sensor/actuator is permitted to be obtained from the module. To avoid damage to the hardware, the module is equipped with overload protection.

Information:

Separate overload protection is implemented for each connection pin of the sensor/actuator power supply, i.e. the power supplies of each connected IO-Link device are galvanically isolated from one another.

If an IO-Link device triggers the overload protection on the module, the subsequent limitation of the supply current only affects this device. All other connected devices are unaffected.

9.26.15.10.4.1 Configuring overload protection for the IO-Link supply

Name:

CfO_SupplyConfig

This register can be used to define how the module supply behaves for all channels when an overload occurs. The following rules apply:

- The overload duration (bits 6-7) corresponds to the time that the supply remains switched on after an overload is detected. The supply is only cut off if the overcurrent occurs for the entire time configured.
- The switch-off duration (bits 4-5) corresponds to the time that the supply remains switched off after an overload-related cutoff until it is switched back on.

For this reason, an overload that occurs over a longer period can cause the module supply to cyclically switch on/off.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|---|-------|---------------------------------------|
| 0 - 3 | Reserved | - | |
| 4 - 5 | Switch-off duration after overload | 00 | 5 ms (bus controller default setting) |
| | | 01 | 20 ms |
| | | 10 | 50 ms |
| | | 11 | Forbidden |
| 6 - 7 | Overload duration until error detection | 00 | 1 ms (bus controller default setting) |
| | | 01 | 4 ms |
| | | 10 | 10 ms |
| | | 11 | Forbidden |

9.26.15.10.4.2 OperatingMode

Name:

CfO_OperatingMode01 to CfO_OperatingMode04

This register is the same as the first byte of register "[ChannelMode](#)" on page 3296 in the IO-Link configuration. It contains all settings of an IO-Link channel that are permitted to be changed at runtime.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|---|
| 0 - 1 | Channel mode | 00 | Mode: Inactive (bus controller default setting) |
| | | 01 | Mode: SIO output The channel's C/Q connector is configured as a digital output. |
| | | 10 | Mode: SIO input The channel's C/Q connector is configured as a digital input. |
| | | 11 | Mode: Operate The channel's C/Q connector is configured for IO-Link data transfer. |
| 2 - 7 | Reserved | - | |

9.26.15.10.5 IO-Link configuration

The module establishes communication with the IO-Link device if register "ChannelMode" on page 3296 of the corresponding channel is configured. The other registers in this section can be used to adapt the data exchange to the application requirements.

9.26.15.10.5.1 ChannelMode

Name:

CfO_ChannelMode01 to CfO_ChannelMode04

The user has the option of setting all channel-specific settings via this register.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UDINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Values | Information |
|---------|---|--------|---|
| 0 - 1 | Channel mode | 00 | Mode: Inactive (bus controller default setting) |
| | | 01 | Mode: SIO output The channel's C/Q connector is configured as a digital output. |
| | | 10 | Mode: SIO input The channel's C/Q connector is configured as a digital input. |
| | | 11 | Mode: Operate The channel's C/Q connector is configured for IO-Link data transfer. |
| 2 - 7 | Reserved | - | |
| 8 - 9 | Threshold value for overcurrent on the channel ¹⁾ (OverCurrentThreshold in Automation Studio configuration) | 00 | 250 mA (bus controller default setting) |
| | | 01 | 125 mA |
| | | 10 | 75 mA |
| | | 11 | 50 mA |
| 10 - 11 | Reserved | - | |
| 12 - 13 | Switch-off duration after overload ¹⁾ (OverloadOffTime in Automation Studio configuration) | 00 | 20 ms (bus controller default setting) |
| | | 01 | 12 ms |
| | | 10 | 6.4 ms |
| | | 11 | 32 ms |
| 14 - 15 | Reserved | - | |
| 16 - 17 | Mode for synchronization | 00 | Free-running (asynchronous) (bus controller default setting) |
| | | 01 | Synchronous (manual) |
| | | 10 | Synchronous (automatic) |
| | | 11 | Impermissible |
| 18 - 19 | Reserved | - | |
| 20 - 23 | Inspection level | 0 | Tests disabled (bus controller default setting) |
| | | 1 | Testing VendorID and DeviceID |
| 24 - 25 | IO-Link timestamp | 00 | No timestamp (bus controller default setting) |
| | | 01 | Input timestamp |
| | | 10 | Output timestamp |
| | | 11 | Input and output timestamps |
| 26 | Format of the IO-Link output timestamp ²⁾ | 0 | 32-bit (DINT) (bus controller default setting) |
| | | 1 | 16-bit (INT) |
| 27 - 32 | Reserved | - | |

- 1) This is overload protection for the C/Q connector of the IO-Link channels (IO-Link data line or SIO output) as opposed to overload protection of the IO-Link power supply.
- 2) This bit informs the module of the format used for the `IoLinkTimestampOut` output timestamp. In Automation Studio, this setting is made implicitly in the I/O configuration together with the selection of the data type for the IO-Link timestamp.

9.26.15.10.5.2 IdentificationRevisionID

Name:

CfO_IdentificationRevisionId01 to CfO_IdentificationRevisionId04

If the identifiers (IDs) of the connected device should be verified during startup, the IO-Link revision with which the check takes place can be disclosed in this register.

| Data type | Values | Information |
|---|--------|--|
| USINT | 0 | The revision read from the device is used. |
| | 16 | The connected device is checked per revision V1.0. |
| | 17 | The connected device is checked per revision V1.1. |
| <p>If the device does not support this standard, error code 41 is output in register "ChannelStatus" on page 3306.</p> | | |

9.26.15.10.5.3 IdentificationVendorID

Name:

CfO_IdentificationVendorId01 to CfO_IdentificationVendorId04

If the Vendor ID is to be verified during startup, then the expected value must be specified in this register. The verification can be enabled by setting the inspection level in the "ChannelMode" on page 3296 register.

Information:

If the expected ID does not match the actual ID of the connected IO-Link device, communication will not be started for this channel.

| Data type | Values | Information |
|-----------|-------------|-----------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 0 |

9.26.15.10.5.4 IdentificationDeviceID

Name:

CfO_IdentificationDeviceId01 to CfO_IdentificationDeviceId04

If the device ID should be verified during startup, then the expected ID of the IO-Link device must be specified in this register. The verification can be enabled by setting the inspection level in the "ChannelMode" on page 3296 register.

Information:

If the expected ID does not match the actual ID of the connected IO-Link device, communication will not be started for this channel.

| Data type | Values | Information |
|-----------|--------------------|-----------------------------------|
| UDINT | 0 to 4,294,967,295 | Bus controller default setting: 0 |

9.26.15.10.5.5 PDI_TypeInfo

Name: CfO_PDI_TypeInfo01 to CfO_PDI_TypeInfo04

To transfer process data from the IO-Link device to the CPU (application), the information is first read from the module and saved temporarily. Typically, 4 bytes are reserved for each piece for registered information (see "IO-Link communication" on page 3303).

This register is used to configure how the incoming IO-Link process data stream (IO-Link frame) is divided. According to this configuration, the IO-Link process data is made available to the application via the corresponding InputData registers. The input data registers are assigned to individual data points with the corresponding data type in the I/O mapping.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| UDINT | See bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|-----------------------|-------------|--|
| 0 to 3 | IO-Link information 1 | 0000 | Array[4] of Bytes (bus controller default setting) |
| | | 0001 | USINT |
| | | 0010 | SINT |
| | | 0011 | UINT |
| | | 0100 | INT |
| | | 0101 | UDINT |
| | | 0110 | DINT |
| | | 0111 | REAL |
| | | 1000 - 1111 | Reserved |
| 4 - 7 | IO-Link information 2 | | Possible values are identical with IO-Link information 1 |
| 8 - 11 | IO-Link information 3 | | |
| 12 - 15 | IO-Link information 4 | | |
| 16 - 19 | IO-Link information 5 | | |
| 20 - 23 | IO-Link information 6 | | |
| 24 - 27 | IO-Link information 7 | | |
| 28 - 31 | IO-Link information 8 | | |

Information:

With setting 0 (Array[4] of Bytes), the bytes are copied from the IO-Link data stream unchanged. In all other modes, the byte order is changed (from big endian to little endian).

9.26.15.10.5.6 PDO_TypeInfo

Name: CfO_PDO_TypeInfo01 to CfO_PDO_TypeInfo04

In order to transfer process data to the IO-Link device, this register is used to configure which data type of the individual "OutputData" on page 3303 registers are used to merge the outgoing IO-Link process data stream (IO-Link frame, see "IO-Link communication" on page 3303). According to this configuration, OutputData registers are assigned to data points with the corresponding data types in Automation Studio (I/O mapping).

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| UDINT | See bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|-----------------------|-------------|--|
| 0 to 3 | IO-Link information 1 | 0000 | Array[4] of Bytes (bus controller default setting) |
| | | 0001 | USINT |
| | | 0010 | SINT |
| | | 0011 | UINT |
| | | 0100 | INT |
| | | 0101 | UDINT |
| | | 0110 | DINT |
| | | 0111 | REAL |
| | | 1000 - 1111 | Reserved |
| 4 - 7 | IO-Link information 2 | | Possible values are identical with IO-Link information 1 |
| 8 - 11 | IO-Link information 3 | | |
| 12 - 15 | IO-Link information 4 | | |
| 16 - 19 | IO-Link information 5 | | |
| 20 - 23 | IO-Link information 6 | | |
| 24 - 27 | IO-Link information 7 | | |
| 28 - 31 | IO-Link information 8 | | |

Information:

With setting 0 (Array[4] of Bytes), the bytes are copied from the IO-Link data stream unchanged. In all other modes, the byte order is changed (from big endian to little endian).

9.26.15.10.5.7 Timing of IO-Link communication

At runtime, the module needs to manage data sets from 2 different communication standards. For efficient X2X Link communication, it is important to make sure that the cycle time of all X2X modules is the same as the bus cycle time.

Cycle times specified in IO-Link

The IO-Link specification defines the timing cycle for polling an IO-Link device. This cycle is called the IO-Link cycle. Valid IO-Link cycle times range from 0.4 ms to 132.8 ms. There are three ranges:

| Area | Increment | Calculation | Valid cycle times |
|------------------|-----------|-----------------------------------|-------------------------------------|
| 0.4 to 6.3 ms | 0.1 ms | Cycle time = 0.1 ms * n + 0.4 ms | 0.4, 0.5, 0.6 to 6.2, 6.3 ms |
| 6.4 to 32.6 ms | 0.4 ms | Cycle time = 0.4 ms * n + 6.4 ms | 6.4, 6.8, 7.2 to 32.2, 32.6 ms |
| 32.0 to 132.8 ms | 1.6 ms | Cycle time = 1.6 ms * n + 32.0 ms | 32.0, 33.6, 35.2 to 131.2, 132.8 ms |

Module timer

An internal module timer that applies globally to all channels serves as the bases for synchronizing the individual channels. Using this defined time basis, X2X and IO-Link communication can be synchronized with each other. The period duration for the module timer can be defined in μ s. To make communication as efficient and deterministic as possible, the module timer is configured in automatic mode to match the X2X Link cycle time by default. If necessary, the start of the module timer can be offset using the "TimerOffset" on page 3301.

The module timer's cycle is synchronized automatically with the X2X cycle. Depending of the ratio between the X2X and module timer cycle time, there may be different ratios between the cycles.

Examples

| | | |
|--------|------------------------------------|---|
| 1 to 1 | (X2X cycle 1000, cycle timer 1000) | → Always exactly one timer cycle per X2X cycle |
| 2 to 1 | (X2X cycle 2000, cycle timer 1000) | → Always exactly two timer cycles per X2X cycle |
| 1 to 2 | (X2X cycle 1000, cycle timer 2000) | → Always exactly one timer cycle per 2 X2X cycles |
| 3 to 5 | (X2X cycle 1500, cycle timer 2500) | → Always exactly 3 timer cycles per 5 X2X cycles |

Synchronous operation

Unlike to free-running operation, synchronous mode and the synchronization cycle time in this operating mode can be configured individually for each channel.

The SYNCHRONIZED operating mode optimizes the interaction between X2X and IO-Link communication. The module's resources were designed for this mode, so this configuration should be used for the module's channels.

- In the mode SYNCHRONIZED (automatic), the module calculates the necessary timing parameters itself. An IO-Link cycle is set that complies with the IO-Link specification. The selected IO-Link cycle time corresponds to the lowest possible multiple of the module timer cycle time that meets the following conditions:
 - Valid IO-Link cycle time
 - Greater than or equal to the minimum cycle time on the device
- In the mode SYNCHRONIZED (manual), the user can configure the module's timing manually. Both the synchronization cycle time and the IO-Link cycle can be defined manually by setting a factor.

Synchronization cycle time

$$\text{Synchronization cycle time} = \text{Timer cycle time} * \text{CfO_ReqCycleMultiple0x}$$

The synchronization ensures that synchronization cycles run parallel with the same synchronization cycle time and are not offset by timer cycles.

IO-Link cycle time

$$\text{IO-Link cycle time} = \text{Synchronization cycle time} / \text{CfO_ReqCycleDivisor0x}$$

The IO-Link cycle is set individually for each channel. If necessary, the IO-Link cycle of a channel can be offset using a channel-specific offset. This allows channels to be adjusted so that their queries end at the same time, for example.

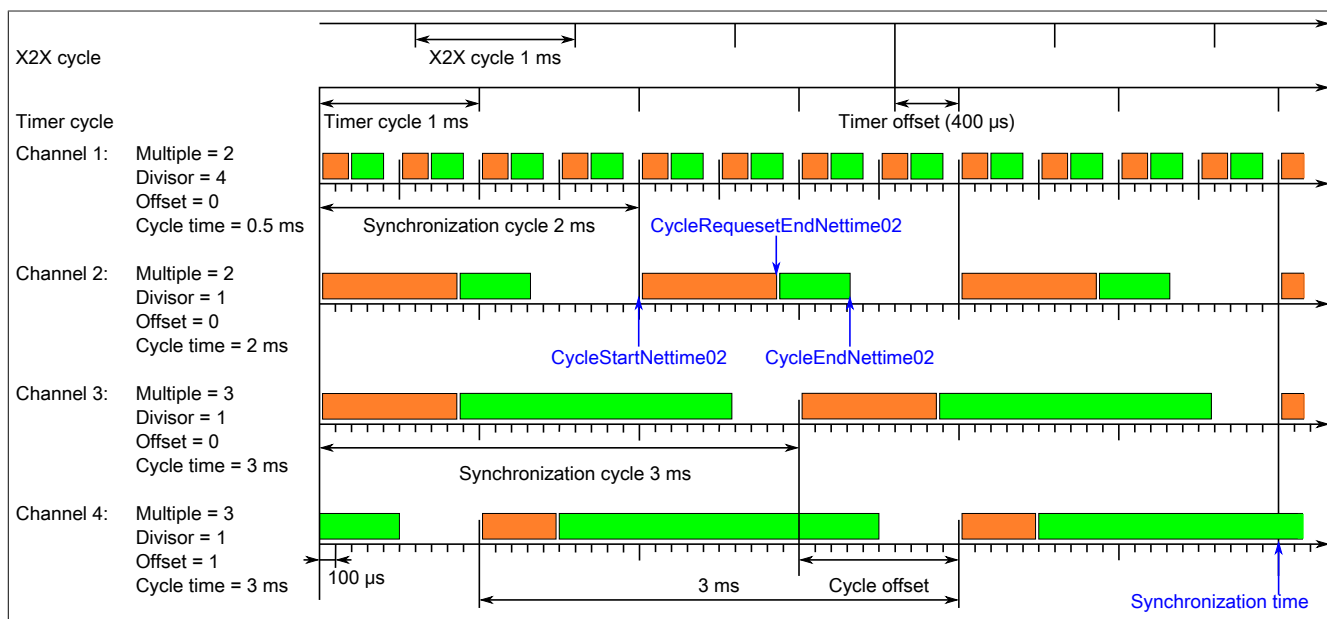

With very short cycle times (<1 ms) it is possible that the data cannot be processed fast enough. When this happens, the subsequent cycles are delayed, which is indicated by the status bit for synchronization being reset.

Information:

If the IO-Link cycle is configured to be less than the device's minimum cycle time, then a cycle that meets the following conditions is selected automatically:

- **Multiple of the module timer cycle**
- **Valid IO-Link cycle time**
- **Greater than or equal to the minimum cycle time on the device**

Example of a configuration

The module timer in this example

- The duration of the module timer period was not defined explicitly. In this case, it corresponds to the X2X Link cycle time.
- An offset of 400 µs was applied to the module timer; i.e. the module timer cycle begins 400 µs after the X2X Link cycle.

IO-Link communication in this example

- The parameters "Multiple" on page 3301 and "Divisor" on page 3301 produce a channel-specific cycle time for IO-Link communication.
- Channels 1 and 2 have a shared synchronization cycle of 2 ms. Channels 3 and 4 have a shared synchronization cycle of 3 ms, which is shifted due to the offset.
- Channels start their query together at the beginning of a shared synchronization cycle.
- The IO-Link cycle of the fourth channel was delayed with an offset of 1 ms.
- All channels have a shared synchronization cycle of 6 ms.

Free-running (asynchronous) mode

If the IO-Link and X2X Link cycle times cannot be synchronized, then the IO-Link cycle time can be specified explicitly. IO-Link communication then runs independently of the module timer and X2X cycle. Except for "CycleEndNettime" on page 3307, no other NetTime data points can be used. The cycle times of free-running IO-Link channels are defined directly via the corresponding registers. However, deviations may occur if the module's resources are exhausted.

TimerCycle

Name:

CfO_TimerCycle

This register can be used to configure synchronous IO-Link communication. If the module timer is not meant to be operated with the same cycle, then it is possible to define the period length of the module timer in μs using this register. This allows channels to be synchronized with one another even if using a very unusual X2X cycle time.

| Data type | Values | Information |
|-----------|--------------------|--|
| UDINT | 0 to 4,294,967,295 | Bus controller default setting: Current X2X cycle time |

TimerOffset

Name:

CfO_TimerOffset

This register can be used to configure synchronous IO-Link communication. If the module timer should run with a timing offset to X2X Link, this register can be used to define how many microseconds in front of or behind the module timer should be shifted.

| Data type | Values | Information |
|-----------|-----------------|-----------------------------------|
| INT | -32768 to 32767 | Bus controller default setting: 0 |

ReqCycleMultiple

Name:

CfO_ReqCycleMultiple01 to CfO_ReqCycleMultiple04

This register can be used to manually configure the synchronization cycle time. This cycle time can be used together with the "ReqCycleDivisor" on page 3301 register to define the IO-Link cycle time. See "Synchronous operation" on page 3299 for an example.

Information:

If this register is not defined for an IO-Link channel or predefined with zero, the values of the Cycle-Multiple and CycleDivisor registers are calculated automatically when the module is started.

| Data type | Values | Information |
|-----------|-------------|-----------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 0 |

ReqCycleDivisor

Name:

CfO_ReqCycleDivisor01 to CfO_ReqCycleDivisor04

This register can be used together with "ReqCycleMultiple" on page 3301 to define the IO-Link cycle time. See "Synchronous operation" on page 3299 for an example.

Information:

If this register is not defined for an IO-Link channel or predefined with zero, the values of the Cycle-Multiple and CycleDivisor registers are calculated automatically when the module is started.

| Data type | Values | Information |
|-----------|-------------|-----------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 0 |

ReqCycleOffset

Name:

CfO_ReqCycleOffset01 to CfO_ReqCycleOffset04

This register can be used to offset the IO-Link cycle of a channel with the synchronization cycle. This offset may be sensible if all channels are running with the same cycle time. In this case, all channels are finished at the same time, which could result in the module not being able to process all data in time. Offsets can be used to prevent these sorts of bottlenecks so that data traffic can be divided up more evenly.

| Data type | Value | Information |
|-----------|------------|--|
| UINT | 0 to 65535 | Configured in timer cycles. Bus controller default setting: 0 |

ReqCycleTime

Name:

CfO_ReqCycleTime01 to CfO_ReqCycleTime04

This register is used with free-running (asynchronous) IO-Link communication. It contains the explicitly defined cycle time for the IO-Link query in μs .

Information:

- In free-running mode, no **NetTime** data points are permitted to be used except for "**CycleEnd-Nettime**" on page 3307.
- If the cycle time predefined for IO-Link communication falls below the device's minimum cycle time, the IO-Link data is queried using the device's minimum cycle time.
- For efficient IO-Link communication, the configured query time should correspond to the specified IO-Link cycle times. If a value is unsuitable, the next suitable cycle time is used automatically.

| Data type | Value | Information |
|-----------|------------|--|
| UINT | 0 to 65535 | In 100 μs steps. Bus controller default setting: 0 |

9.26.15.10.6 IO-Link communication

If the corresponding IO-Link channel of the module has been configured to "Operate" in Automation Studio, the IO-Link module attempts to exchange process data with the connected IO-Link device. For each active IO-Link channel, 8 `InputData0x_y` and 8 `OutputData0x_y` registers are allocated in the memory of the module.

| | | | | | | | | | | | | | |
|----------|---------------|-------|-------|-------|---------------|-------|-------|-------|-----|---------------|-------|-------|-------|
| Register | InputData0x_1 | | | | InputData0x_2 | | | | ... | InputData0x_8 | | | |
| | 8-bit | 8-bit | 8-bit | 8-bit | 8-bit | 8-bit | 8-bit | 8-bit | | 8-bit | 8-bit | 8-bit | 8-bit |

To define the actual IO-Link frame, you must define how many of the maximum 8 registers are used as well as the data type of the IO-Link data.

| | | | | | | | | | | | | | |
|----------|---------------|-------|-------|-------|---------------|-------|-------|-------|-----|---------------|-------|-------|-------|
| Register | InputData0x_1 | | | | InputData0x_2 | | | | ... | InputData0x_8 | | | |
| | SINT | 8-bit | 8-bit | 8-bit | INT | 8-bit | 8-bit | 8-bit | | DINT | 8-bit | 8-bit | 8-bit |

The IO-Link frame for communication with the IO-Link device results from these initialized data points.

In order to transfer the IO-Link data to the PLC, the bandwidth of the X2X Link network must also be taken into account when defining the data type for the IO-Link communication. This limitation can be minimized if the "OCTET" data points or "multiplexed OCTET" data points are used instead of the standard data types.

"OCTET" byte arrays:

8 registers with up to 32 bits are available per channel and direction. This way, 8 data points can be transferred. If this amount of data is insufficient, a byte array can be used to generate the IO-Link frame. The user must manage the distribution of IO-Link frames within the application and observe the byte order in the IO-Link device.

"Multiplexed OCTET" byte arrays:

When transferring the IO-Link data via the X2X Link network, it is important to note that not all 32 bytes of the 4 IO-Link channels can be simultaneously registered on the cyclic part of the X2X Link network. In the input direction, the module has been extended in this respect. Time-multiplexed data transfer can take place in the background. Depending on the amount of data, several X2X cycles may be required to transfer new data between the module and the controller. This mode is not available in the output direction. Therefore, IO-Link output data can only be generated with a maximum length of 27 bytes.

SIO mode

"SIO" stands for "standard I/O" and defines an alternative use for the C/Qx connection. If a channel of the module is not required for IO-Link communication, the pin can be used as standard I/O. The user can decide whether to use the standard I/O as input or output. The IO-Link standard also permits IO-Link communication to be stopped and restarted. If IO-Link communication is stopped at runtime, the C/Qx connection can be used as a standard output.

9.26.15.10.6.1 OutputData

Name:

OutputData01_1 to OutputData04_8

Output data from the IO-Link device in IO-Link communication mode. A byte array is also a possible alternative. The user then has to make sure that the bytes are divided up into the necessary data types.

The "[PDO_TypeInfo](#)" on page 3298 register can be used to configure how many bytes should be applied to the IO-Link frame from the output registers.

| Data type | Value |
|-----------|---------------------------------|
| USINT | 0 to 255 |
| SINT | -128 to 127 |
| UINT | 0 to 65535 |
| INT | -32,768 to 32,767 |
| UDINT | 0 to 4,294,967,295 |
| DINT | -2,147,483,648 to 2,147,483,647 |
| REAL | -3.4E38 – 3.4E38 |

9.26.15.10.6.2 Digital SIO outputs

Name:

DigitalOutput01 to DigitalOutput04

DisablePowerSupply01 to DisablePowerSupply04

If a channel is being operated in SIO mode (SIO output), this register can be used to control the SIO output of the IO-Link channel. It is also possible switch on/off the supply for each IO-Link channel individually.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|----------------------|-------|--|
| 0 | DigitalOutput01 | 0 | Reset digital SIO output 01 |
| | | 1 | Set digital SIO output 01 |
| ... | | ... | |
| 3 | DigitalOutput04 | 0 | Reset digital SIO output 04 |
| | | 1 | Set digital SIO output 04 |
| 4 | DisablePowerSupply01 | 0 | Switch on supply for IO-Link channel 01 |
| | | 1 | Switch off supply for IO-Link channel 01 |
| ... | | ... | |
| 7 | DisablePowerSupply04 | 0 | Switch on supply for IO-Link channel 04 |
| | | 1 | Switch off supply for IO-Link channel 04 |

9.26.15.10.6.3 InputData

Name:

InputData01_1 to InputData04_8

Input data from the IO-Link device in IO-Link communication mode. A byte array is also a possible alternative. The user then has to make sure that the bytes are divided up into the necessary data types.

| Data type | Value |
|-----------|---------------------------------|
| USINT | 0 to 255 |
| SINT | -128 to 127 |
| UINT | 0 to 65535 |
| INT | -32,768 to 32,767 |
| UDINT | 0 to 4,294,967,295 |
| DINT | -2,147,483,648 to 2,147,483,647 |
| REAL | -3.4E38 – 3.4E38 |

9.26.15.10.6.4 Digital SIO inputs

Name:

DigitalInput01 to DigitalInput04

If a channel is being operated in SIO mode (SOI input), this register can be used to read the input status of the channel.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------|-------|----------------------------|
| 0 | DigitalInput01 | 0 | Reset digital SIO input 01 |
| | | 1 | Set digital SIO input 01 |
| ... | | ... | |
| 3 | DigitalInput04 | 0 | Reset digital SIO input 04 |
| | | 1 | Set digital SIO input 04 |
| 4 - 7 | Reserved | - | |

9.26.15.10.7 IO-Link status response

The status registers for IO-Link communication are explained in the following chapter. The status information provides information about the current situation between the module and the IO-Link device. They can be retrieved from the controller and evaluated in the application task.

9.26.15.10.7.1 Sync (status byte)

Name:

Synchronized01 to Synchronized04

CycleEnd01 to CycleEnd04

The module uses this status register to report whether error-free communication with the device was possible during the last module cycle.

- The CycleEnd bits indicate whether the last data transmitted to the IO-Link device has been processed. The CycleEnd bits are reset after each X2X cycle.
- The synchronized bits indicate that the channel is synchronized without errors.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|----------------|-------|--|
| 0 | Synchronized01 | 0 | Synchronization for channel 1 not OK |
| | | 1 | Synchronization for channel 1 OK |
| ... | | ... | |
| 3 | Synchronized04 | 0 | Synchronization for channel 4 not OK |
| | | 1 | Synchronization for channel 4 OK |
| 4 | CycleEnd01 | 0 | I/O cycle end: No new IO-Link data |
| | | 1 | I/O cycle end: New data transmitted and received |
| ... | | ... | |
| 7 | CycleEnd04 | 0 | I/O cycle end: No new IO-Link data |
| | | 1 | I/O cycle end: New data transmitted and received |

9.26.15.10.7.2 Overload (status byte)

Name:

Overload01 to Overload04

This status register is used by the module to report whether an overload in the form of overcurrent or overtemperature occurred in the channel supply.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|------------------------|
| 0 | Overload01 | 0 | Channel 1: No overload |
| | | 1 | Channel 1: Overload |
| ... | | ... | |
| 3 | Overload04 | 0 | Channel 4: No overload |
| | | 1 | Channel 4: Overload |
| 4 - 7 | Reserved | - | |

9.26.15.10.7.3 ChannelStatus

Name:

ChannelStatus01 to ChannelStatus04

This register is used to show the current status of the IO-Link channel.

| Data type | Value | Information | Status |
|-----------|-----------|--|--|
| USINT | 0 | Channel inactive | Disabled |
| | 1 | Use as digital SIO output | SIO mode |
| | 2 | Use as digital SIO input | |
| | 3 | Startup of IO-Link device, PREOPERATIONAL mode | Communication is running but no process data is exchanged. However, acyclic access is also possible. |
| | 4 | Operation, OPERATE mode | Communication is running |
| | 5 | Operation, parameter server data OK | |
| | 6 | Parameter server: Upload active | Communication is running and process data is being returned. |
| | 7 | Parameter server: Download active | |
| | 8 | Parameter server: Deleting active | |
| | 9 | IODD parameters are written | |
| | 10 to 20 | Reserved | |
| | 21 | General error in the parameter server . For example: <ul style="list-style-type: none"> Parameter server not supported Error accessing an object that is managed by the parameter server Internal error | Communication is running. However, an error has occurred on the parameter server. Parameter server errors can be acknowledged via the " DsControl " on page 3310 register. |
| | 22 | Parameter server locked by IO-Link device | |
| | 23 | Parameter server empty: Tried to load data to the IO-Link device even though no data is saved in EEPROM | |
| | 24 | New serial number recognized: The user must decide via the " DsControl " on page 3310 register what has to be done (Upload – Download – Restore default values) | |
| | 25 | Parameter server not compatible (new DeviceID or new VendorID recognized): The data in EEPROM is not suitable for the connected IO-Link device. The user must decide via the " DsControl " on page 3310 register whether an upload should be carried out. | |
| | 26 | Upload request received. The user must decide via the " DsControl " on page 3310 register what must be done (Upload – Download – Restore default values). | |
| | 27 | The parameter checksum of the IO-Link device has changed: The user must decide via the " DsControl " on page 3310 register what must be done (Upload – Download – Restore default values). | |
| | 28 | Error when sending the SAVE command | |
| | 29 | Reserved | |
| | 30 | Process data invalid | Communication is running. However, process data was marked as invalid by the device. |
| | 31 - 39 | Reserved | |
| | 40 | No connection | No communication |
| | 41 | The configured revision ID is not supported by the connected device. | |
| | 42 | The DeviceID and VendorID of the connected IO-Link device do not match the predefined IDs. | Communication is running but no process data is exchanged. However, acyclic access is also possible. |
| | 43 | The configured serial number does not match the serial number of the connected device. | |
| | 44 | Timestamp error The IO-Link device does not support IO-Link timestamps. | |
| | 45 | Error starting up the device | No communication |
| | 46 to 255 | Reserved | |

9.26.15.10.7.4 FrameCount

Name:

FrameCount01 to FrameCount04

Received IO-Link frames are counted in this register. Unlike the [sync bits](#), the FrameCount register ensures that all frames are actually recognized. This is the case even if X2X cycles are lost or if the IO-Link cycle is faster than the X2X cycle.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

9.26.15.10.7.5 CycleStartNettime

Name:

CycleStartNettime01 to CycleStartNettime04

This register is used to read out the NetTime value at the start time of the last IO-Link cycle.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Value |
|-----------|---------------------------------|
| INT | -32768 to 32767 |
| DINT | -2,147,483,648 to 2,147,483,647 |

9.26.15.10.7.6 CycleEndNettime

Name:

CycleEndNettime01 to CycleEndNettime04

This register is used to read out the NetTime value at the end time of the last IO-Link cycle.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Value |
|-----------|---------------------------------|
| INT | -32768 to 32767 |
| DINT | -2,147,483,648 to 2,147,483,647 |

9.26.15.10.8 IO-Link event interface

The event interface involves interrupt-controlled background communication. It enables the connected IO-Link devices to transmit special messages, or "event codes", to the master.

The module can receive up to 16 of these messages, buffer them and make them available for retrieval from the controller. Essentially, FIFO memory is used for this; this is managed independently of the cyclic communication.

Information:

If a message is received via the event interface and the FIFO memory is full, the oldest message in the buffer is overwritten. In rare cases, this can lead to messages being lost before they have been evaluated.

Sequence for reading an event

- A new event was triggered by the device. This is indicated by an increase in ["EventPortSeq" on page 3308](#).
- Event data can be read using registers ["EventQualifier" on page 3308](#) and ["EventCode" on page 3308](#).
- The event must be acknowledged. To do so, the sequence number from ["EventPortSeq" on page 3308](#) must be copied to the sequence number from ["EventQuit" on page 3309](#).
- The next event is specified only after the event is acknowledged.

9.26.15.10.8.1 EventPortSeq

Name:
EventPortSeq

As soon as a new event is generated by an IO-Link device, the sequence number is increased in this register. The affected channel number is also displayed.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|---------|-----------------|
| 0 - 3 | Sequence number | 0 to 15 | |
| 4 - 5 | IO-Link channel number | 00 | IF1 (channel 1) |
| | | 01 | IF2 (channel 2) |
| | | 10 | IF3 (channel 3) |
| | | 11 | IF4 (channel 4) |
| 6 - 7 | Reserved | 0 | |

9.26.15.10.8.2 EventQualifier

Name:
EventQualifier

This register contains additional information about the event.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------------------------------|-------|--|
| 0 - 2 | Instance layer generated by the event | 000 | Unknown |
| | | 001 | Hardware |
| | | 010 | Data exchange layer of the IO-Link device |
| | | 011 | Application layer of the IO-Link device |
| | | 100 | Application |
| 3 | Cause of the event | 0 | Device |
| | | 1 | Master |
| 4 - 5 | Type of event | 00 | Reserved |
| | | 01 | Information |
| | | 10 | Warning |
| | | 11 | Errors |
| 6 - 7 | Mode of the event | 00 | Reserved |
| | | 01 | One-time event |
| | | 10 | Event no longer reported (e.g. voltage OK again) |
| | | 11 | Event reported (e.g. voltage too low) |

9.26.15.10.8.3 EventCode

Name:
EventCode

The event code of the event being transferred is indicated in this register. The event codes may be vendor-specific event codes or event codes defined in the IO-Link specification.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.15.10.8.4 EventsLeft

Name:
EventsLeft

This register indicates the number of as yet unprocessed events in the FIFO buffer.

| Data type | Value |
|-----------|---------|
| USINT | 0 to 16 |

9.26.15.10.8.5 EventQuit

Name:
EventQuit

This register can be used to acknowledge events. This is done by copying the sequence number of the event to be acknowledged to this register.

| Data type | Values |
|-----------|---------|
| USINT | 0 to 15 |

9.26.15.10.8.6 EventQuitReadBack

Name:
EventQuitReadBack

This register contains the sequence number of the most recently acknowledged event.

| Data type | Value |
|-----------|---------|
| USINT | 0 to 15 |

9.26.15.10.9 IO-Link parameter server

The parameter server is a function that is defined by the IO-Link specification. This function is normally enabled in the module and can be managed with register "[CfO_DS_Config](#)" on page 3311.

The parameter server permits the module to read configuration parameters of the connected IO-Link device. The data of the third-party device is stored in the EEPROM and can then be restored automatically, e.g. after replacing the IO-Link device.

Information:

The selection of the transferred configuration data depends on the connected IO-Link device. The module only functions as data storage. It requests the configuration data of the IO-Link device, stores the response and transmits the received information back to the connected IO-Link device, if required.

A change to the read parameter server data in the memory of the module is not foreseen.

Event code 0xFF91

The module is able to process the "data memory upload request" (event code 0xFF91) of the connected IO-Link device in order to automatically manage the memory of the parameter server in the module.

The standard does not specify exactly when the event code must be generated. Most IO-Link devices generate it as soon as the configuration parameters change. With some IO-Link devices, it can be advantageous to request the upload and download processes manually. For this purpose the module includes an option for adapting the transfer of the parameter server data to the individual application requirements.

Information:

Automatic management can be used if the connected third-party IO-Link device supports the parameter server function and can generate the event code.

The parameter server

If supported by the IO-Link device, the IO-Link parameter server can be used to read the application-specific device configuration from the IO-Link master, for example. The parameter server of the module is generally activated and can be used with the help of a controller register.

Which data storage parameters are transferred depends on the connected IO-Link device. The read information is stored in EEPROM on the module and can be fed back automatically after replacing the device, for example.

The module is capable of processing the data storage upload request (event code 0xFF91) of the IO-Link specification. The request is usually triggered if parameters on the device are changed. In this case, depending on the configuration, an upload of data storage data can be started (standard).

Automatic management of data storage parameters

Automatic management has been designed according to IO-Link specification. Since the IO-Link standard exhibits a degree of tolerance here, it is possible that some IO-Link devices may have to be handled differently. This can be configured using the register.

An upload/download is performed under the following conditions:

- DsControl0x = 1
- While the device is starting up or if a data storage upload request has been received.

Offline configuration

With offline configuration, the configuration data set up for the device in Automation Studio is stored in the project. This data is then used to configure the CPU automatically when the project is downloaded or data is generated for the memory card. In contrast to the parameter server, where values are read from an existing device, the values in this case are defined explicitly in the application. The values are automatically configured only one time after the download. This procedure only occurs again if a new parameter file is received from Automation Studio, the device is replaced or if the download is started manually by the library.

This function works independently of the parameter server. If the parameter server is still enabled, however, it can be started as needed after the offline configuration to store the corresponding data. In the event of a replaced device, the data can be loaded to the device from the parameter server.

9.26.15.10.9.1 DsControl

Name:

DsControl01 to DsControl04

This register can be used to control the "parameter server" on page 3309 manually. Each action is carried out exactly once when the corresponding value is set. If the same action should be executed multiple times, then this register must be set to the value 0 beforehand.

| Data type | Value | Information |
|-----------|----------|--|
| USINT | 0 | No action (bus controller default setting) |
| | 1 | Operating mode of the parameter server: Automatic upload and download |
| | 2 | Upload if data storage parameters are available on the device |
| | 3 | Download if data storage parameters are available in the CPU's memory and the device can process them |
| | 4 | Acknowledge error status from parameter server (see "ChannelStatus" on page 3306: error messages 21 to 28) |
| | 5 | Delete data storage parameters on the CPU's memory |
| | 6 | Start dummy upload. Starts an upload without saving the data. This can be used to acknowledge an upload request. |
| | 7 to 255 | Reserved |

9.26.15.10.9.2 DsProgress

Name:

DsProgress01 to DsProgress04

The module uses this register to report the progress of the upload or download from the parameter server. The values from 0 to 100 can be used for implementing a progress display.

| Data type | Value |
|-----------|----------|
| USINT | 0 to 100 |

9.26.15.10.9.3 CfO_DS_Config

Name:

CfO_DS_Config01 to CfO_DS_Config04

This register can be used to set the behavior of the parameter server module (when operating the parameter server manually). By doing this, a corresponding reaction is assigned to every trigger event.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| UDINT | See bit structure. | 0 |

Bit structure:

| Bit | Event | Value | Reaction |
|---------|---|-------|---|
| 0 - 3 | The device ID of the connected device no longer matches the device ID saved together with the parameters. | 000 | No reaction (bus controller default setting) |
| | | 001 | Cancel |
| | | 010 | User-defined reaction. See "ChannelStatus" on page 3306: Status message 25 |
| | | 011 | Upload |
| 4 - 7 | The device transmitted an upload request. | 000 | No reaction (bus controller default setting) |
| | | 001 | Cancel |
| | | 010 | User-defined reaction. See "ChannelStatus" on page 3306: Status message 26 |
| | | 011 | Upload |
| 8 - 11 | A new parameter checksum was detected when starting the device. | 000 | No reaction (bus controller default setting) |
| | | 001 | Cancel |
| | | 010 | User-defined reaction. See "ChannelStatus" on page 3306: Status message 27 |
| | | 011 | Upload |
| | | 100 | Download |
| 12 - 15 | The serial number of the connected device no longer matches the serial number saved together with the parameters. | 000 | No reaction (bus controller default setting) |
| | | 001 | Cancel |
| | | 010 | User-defined reaction. See "ChannelStatus" on page 3306: Status message 24 |
| | | 011 | Upload |
| | | 100 | Download |
| 16 - 23 | Reserved | - | |
| 24 - 26 | Specifies the order that individual events are checked | 000 | Device ID, serial number, upload request, parameter checksum (bus controller default setting) |
| | | 001 | DeviceID, serial number, parameter checksum, upload request |
| | | 010 | DeviceID, upload request, parameter checksum, serial number |
| | | 011 | DeviceID, upload request, serial number, parameter checksum |
| | | 100 | DeviceID, parameter checksum, upload request, serial number |
| | | 101 | DeviceID, parameter checksum, serial number, upload request |
| 27 - 31 | Reserved | - | |

9.26.15.10.9.4 CfO_DS_SaveCtrl

Name:

CfO_DS_SaveCtrl01 to CfO_DS_SaveCtrl04

This register is used together with "CfO_DS_SaveData" on page 3312.

Some IO-Link devices must be instructed to save transferred data storage parameters in remanent memory after a download. In order for these parameters to be applied to remanent memory on these devices, the recorded index and subindex in these registers must be sent together with the save command (e.g. value 163 on index 2, subindex 0).

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| UDINT | See bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|-------------|----------|--|
| 0 - 15 | Index | 0 to 255 | Device-specific index for save command |
| 16 - 24 | Subindex | 0 to 255 | Device-specific subindex for save command |
| 24 - 26 | Data length | 0 | Save command disabled |
| | | 1 to 4 | The data length of the save command estimated by the device in bytes |
| 27 - 31 | Reserved | | |

9.26.15.10.9.5 CfO_DS_SaveData

Name:

CfO_DS_SaveData01 to CfO_DS_SaveData04

This register is used together with "[CfO_DS_SaveCtrl](#)" on page 3311 and contains the value written to the index configured in the CfO_DS_SaveCtrl register.

| Data type | Values | Information |
|-----------|--------------------|-----------------------------------|
| UDINT | 0 to 4,294,967,295 | Bus controller default setting: 0 |

9.26.15.10.10 IO-Link timestamp

The IO-Link timestamp registers allow the assignment of IO-Link timestamps to the NetTime of a controller, and vice versa.

This makes it possible for value changes of the IO-Link device to be assigned exactly to the NetTime of the controller, and vice versa. Events can be captured or triggered with a higher timing resolution than would be possible with the IO-Link cycle. This allows a highly precise timed response from the controller to signals from the sensor, and vice versa. The resolution depends on the devices being used.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

Examples

- For an input device, the timestamp is saved directly by the device when a certain event occurs (e.g. photo-electric sensor triggered) and then transferred via IO-Link. The IO-Link master converts this IO-Link-specific timestamp to a NetTime timestamp that can be used across the system.
- In the output direction, a converted timestamp is transferred to the device via IO-Link. The output device responds at the corresponding instant and executes the intended event (e.g. closes a switch).

Information:

- **The timestamp function is device-specific and not supported by every IO-Link device.**
- **This function cannot be used if the channel is being operated in free-running mode (asynchronous).**

9.26.15.10.10.1 IoLinkTimestampIn

Name:

IoLinkTimestampIn01 to IoLinkTimestampIn04

This register indicates the NetTime instant at which the application event occurred.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Value |
|-----------|---------------------------------|
| INT | -32768 to 32767 |
| DINT | -2,147,483,648 to 2,147,483,647 |

9.26.15.10.10.2 IoLinkTimestampInStatusSeq

Name:

IoLinkTimestampInStatusSeq01 to IoLinkTimestampInStatusSeq04

This register indicates information about the [input timestamp](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------------------------|---------|--|
| 0 - 3 | Sequence number | 0 to 15 | The sequence number is increased by 1 each time a valid timestamp is received. If the sequence number is increased by more than 1, it means that the event was lost. |
| 4 | Event 1 triggered by application | x | Signal state when timestamp occurs |
| 5 | Event 2 triggered by application | x | Signal state when timestamp occurs Example: Signal state when timestamp occurs <ul style="list-style-type: none"> – Photoelectric sensor triggered → This bit = 0 – Photoelectric sensor not triggered → This bit = 1 |
| 6 | Reserved | - | |
| 7 | Timestamp error | 0 | No error |
| | | 1 | An error occurred on the IO-Link device. Possible causes: <ul style="list-style-type: none"> • More timestamps were generated than could be transferred. • The value of the IO-Link timestamp exceeded the permitted range of values. In both cases, it may help to reduce the IO-Link cycle time. |

9.26.15.10.10.3 IoLinkTimestampOut

Name:

IoLinkTimestampOut01 to IoLinkTimestampOut04

The user can write the NetTime for the output timestamp to this register.

The NetTime is automatically converted to an IO-Link timestamp. The event is triggered at the defined NetTime. The "[IoLinkTimestampOutStatus](#)" on page 3314 register is used for acknowledgment.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

Information:

The NetTime must be at least three IO-Link cycles in the future; otherwise, a warning is set in [IoLinkTimestampOutStatus](#).

This register's data type must match the format configured in register "[ChannelMode](#)" on page 3296, bit 26.

| Data type | Values | Information |
|-----------|---------------------------------|-----------------------------------|
| INT | -32768 to 32767 | Bus controller default setting: 0 |
| DINT | -2,147,483,648 to 2,147,483,647 | |

9.26.15.10.10.4 IoLinkTimestampOutCtrlSeq

Name:

IoLinkTimestampOutCtrlSeq01 to IoLinkTimestampOutCtrlSeq04

This register is used to control how the [timestamp](#) is applied.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------------|---------|--|
| 0 - 3 | Sequence number | 0 to 15 | Output timestamp and application event bits applied when the sequence number is increased by 1 |
| 4 | Application event 1 | x | Output state at the timestamp |
| 5 | Application event 2 | x | Output state at the timestamp |
| 6 | Acknowledge warning | 0 | Do not acknowledge (bus controller default setting) |
| | | 1 | Acknowledge warning |
| 7 | Acknowledging errors | 0 | Do not acknowledge (bus controller default setting) |
| | | 1 | Acknowledging errors |

9.26.15.10.10.5 IoLinkTimestampOutStatus

Name:

IoLinkTimestampOutStatus01 to IoLinkTimestampOutStatus04

This register is used to indicate the status of the [output timestamp](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------------------|---------|--|
| 0 - 3 | Acknowledgment of sequence number | 0 to 15 | When an output timestamp has been successfully applied, then the sequence number from "IoLinkTimestampOutCtrlSeq" on page 3313 is acknowledged here. |
| 4 - 5 | Reserved | - | |
| 6 | Warning | 0 | No warning |
| | | 1 | A timestamp was not at least 3 cycles in the future, so output may be delayed. |
| 7 | Errors | 0 | No error |
| | | 1 | More timestamps were transferred to the module than could be output. |

9.26.15.10.11 IO-Link device IDs

IO-Link device IDs are defined by the manufacturer of the IO-Link device and cannot be modified by the user. They can be used to clearly identify a connected IO-Link device.

9.26.15.10.11.1 VendorId

Name:

VendorId01 to VendorId04

This register contains the unique vendor ID of the IO-Link device.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.15.10.11.2 DeviceId

Name:

DeviceId01 to DeviceId04

This register contains the unique ID of the IO-Link device.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.15.10.11.3 FunctionId

Name:

FunctionId01 to FunctionId04

This register contains the device's function class provided by the vendor.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.15.10.11.4 CycleTime

Name:

CycleTime01 to CycleTime04

Some IO-Link devices cannot handle high-speed cycles and require a higher cycle time. This register can be used to read back the channel's IO-Link cycle time currently being used. The time used for communication is always a multiple of 100 μ s, e.g. 50 for 5 ms cycle time.

| Data type | Value | Information |
|-----------|------------|--------------------------------|
| UINT | 0 to 65535 | Specified in 100 μ s steps |

9.26.15.10.11.5 CycleMultible

Name: CycleMultible01 to CycleMultible04

This register can be used to read back the "multiplier" on page 3301 currently being used for the channel's IO-Link cycles.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.15.10.11.6 CycleDivisor

Name:

CycleDivisor01 to CycleDivisor04

This register can be used to read back the "divisor" on page 3301 currently being used for the channel's IO-Link cycles.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.15.10.11.7 MinCycleTime

Name:

MinCycleTime01 to MinCycleTime04

This register can be used to read back the minimum IO-Link cycle time. The minimum IO-Link cycle time depends on the IO-Link device and is read from the module after establishing communication with the IO-Link device.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.15.10.11.8 PDI_Size

Name:

PDI_Size01 to PDI_Size04

This register can be used to read back the size of the input process data defined by the device. This value is read when starting up the IO-Link device.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.26.15.10.11.9 PDO_Size

Name:

PDO_Size01 to PDO_Size04

This register can be used to read back the size of the output process data defined by the device. This value is read when starting up the IO-Link device.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.26.15.10.11.10 Baud rate

Name:

Baudrate01 to Baudrate04

This register can be used to read back the baud rate defined by the IO-Link device. This value is read when starting up the IO-Link device.

| Data type | Value | Information |
|-----------|-------|---------------------|
| USINT | 1 | COM1 = 4.8 kbit/s |
| | 2 | COM2 = 38.4 kbit/s |
| | 3 | COM3 = 230.4 kbit/s |

9.26.15.10.11.11 IoLinkVersionID

Name:

IoLinkVersionID01 to IoLinkVersionID04

This register can be used to read back the IO-Link version.

| Data type | Value | Information |
|-----------|-------------|-------------|
| USINT | 16 (= 0x10) | V1.0 |
| | 17 (= 0x11) | V1.1 |

9.26.15.10.12 IO-Link device configuration

The following possibilities are available for configuring an IO-Link device:

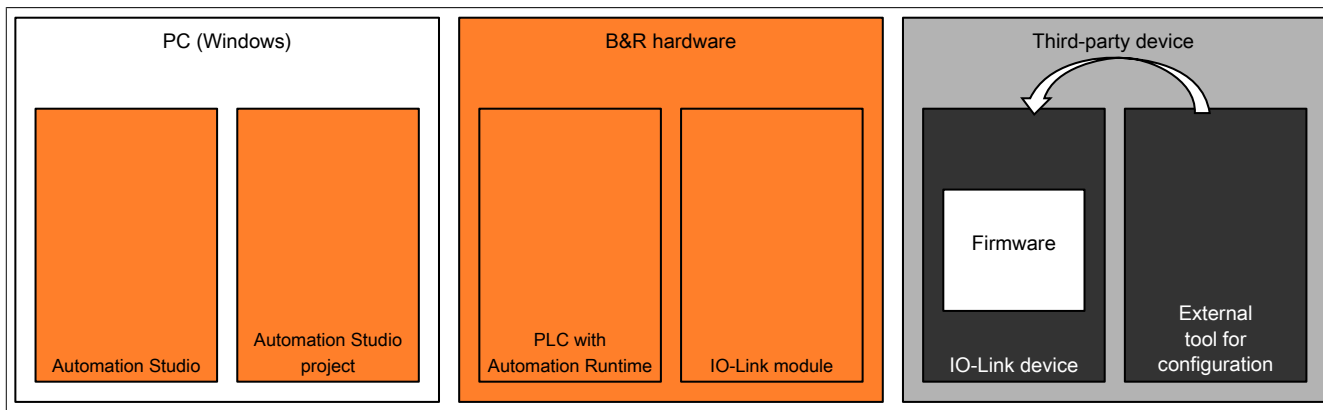

- Direct configuration
- Configuration via IODD/DTM support
The manufacturer must provide a corresponding IODD or DTM file for this.
- Restoring a configuration via parameter server
The IO-Link device must support the "Parameter server" function in accordance with the IO-Link V1.1 specification for this.

Information:

Another way to configure an IO-Link device is to use library "AsloLink". This library is not part of this description.

9.26.15.10.12.1 Direct configuration

Direct configuration takes place independently of the B&R hardware and software used. Parameters can be entered via an additional configuration device, integrated display or other operating elements on the IO-Link device, for example.

Advantage

It is advantageous for individual devices because it is possible to start up the IO-Link device using resources from the manufacturer.

If problems arise while configuring the IO-Link device, checking which software component is causing the error is not necessary.

Disadvantage

Each individual IO-Link device must be manually preconfigured.

In some circumstances, the user must have several development environments on one computer.

9.26.15.10.12.2 IODD/DTM support

Using the integrated FDT container, IO-Link devices can be configured using Automation Studio. IODD/DTM support for IO-Link devices is available online as well as offline.

Information:

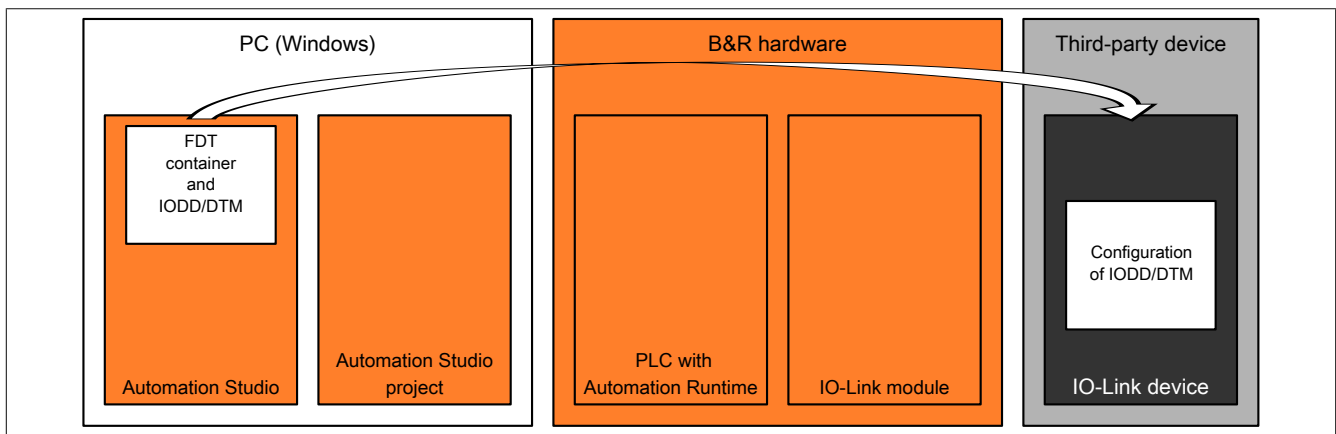

To use Automation Studio to configure IO-Link devices, a corresponding hardware description file (IODD or DTM) must be downloaded and installed.

Information:

This function is available in Automation Runtime V4.08 and later.

IODD/DTM (online)

During online configuration, the FDT container in Automation Studio communicates directly with the IO-Link device. After the connection is established, the configuration parameters can be modified as needed.

Advantage

No additional devices are usually required to configure the IO-Link device. All settings can be modified by the user in a single development environment.

Disadvantage

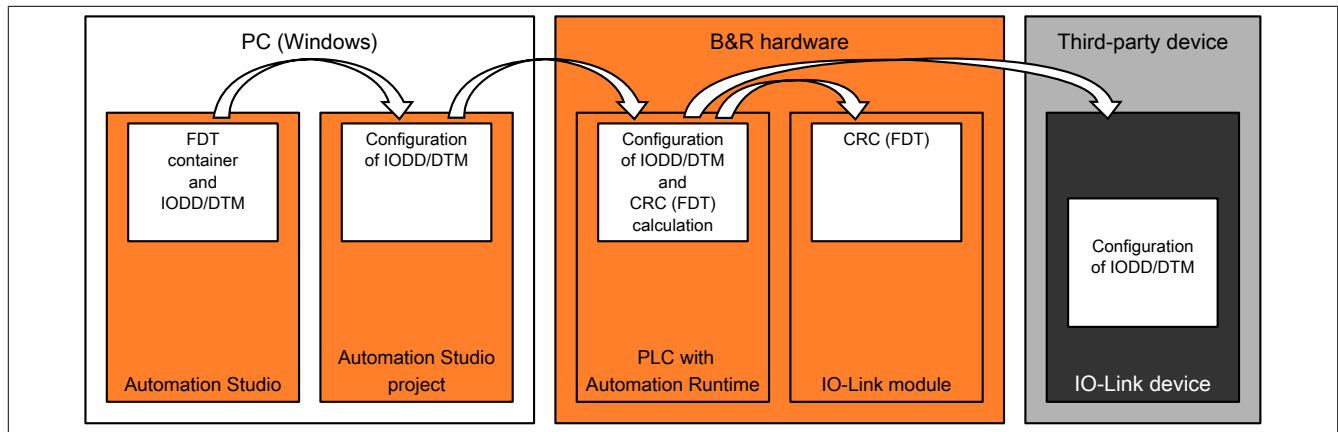

Each IO-Link device must be configured individually.

IODD/DTM (offline)

During offline configuration, the parameter set that can be entered via the IODD or DTM file is stored in the Automation Studio project. During the download, the parameter set for the IO-Link device is transferred to the controller and then from there to the IO-Link device via the module.

Procedure

- 1) When the IO-Link module is started, the checksum (CRC_{FDT}) for the current parameter set is calculated.
- 2) If the previously stored checksum deviates from the present calculated one, the parameter set is transferred to the IO-Link device.
- 3) After the parameter set has been transferred, the associated checksum (CRC_{FDT}) is saved on the IO-Link module and can be used for future comparisons.
- 4) If the parameter set changes, a new checksum (CRC_{FDT}) results from the succeeding reboot of the controller and steps 2 and 3 are repeated.

Advantage

The configuration parameters of the IO-Link device are stored as part of the Automation Studio project. The user can work within a development environment and define all settings.

For series-produced machine, the IO-Link devices used later do not have to be preconfigured individually.

Disadvantage

The configuration options for the IO-Link device depend on the extent of the IODD or DTM file.

Information:

Before the parameter set is transferred to the IO-Link device, the controller checks if the connected device has the correct device ID. If the device ID is incorrect, the procedure is canceled. The parameter set is not transferred, and the checksum is not saved.

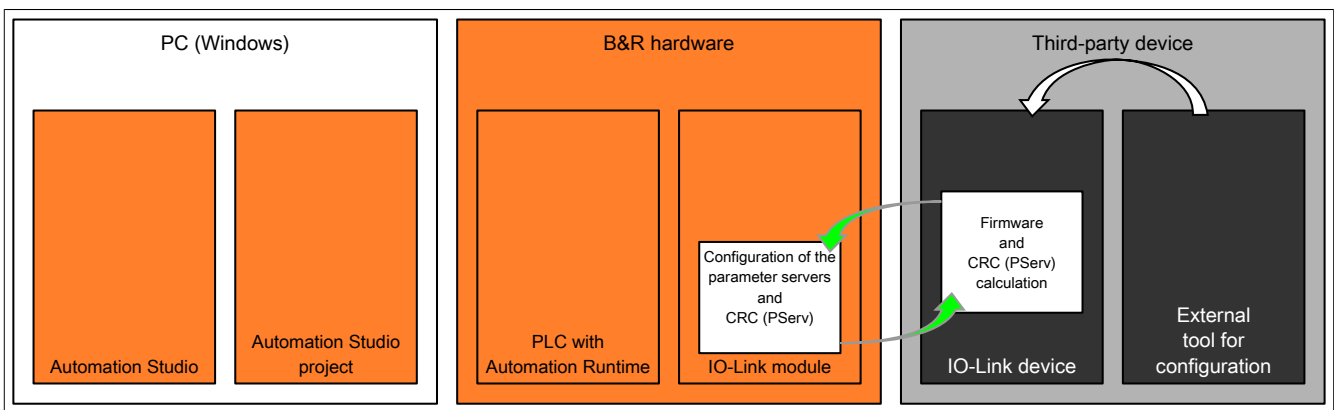

9.26.15.10.12.3 Parameter server

The function "parameter server" is defined in IO-Link specification V1.1 and later. This function allows an IO-Link device to be replaced without requiring any specialist knowledge on the part of maintenance personnel.

This is done by storing the configuration loaded on the IO-Link device on the IO-Link module. In addition, a checksum ($CRC_{P_{Serv}}$) is calculated to allow a simple comparison of the parameter sets.

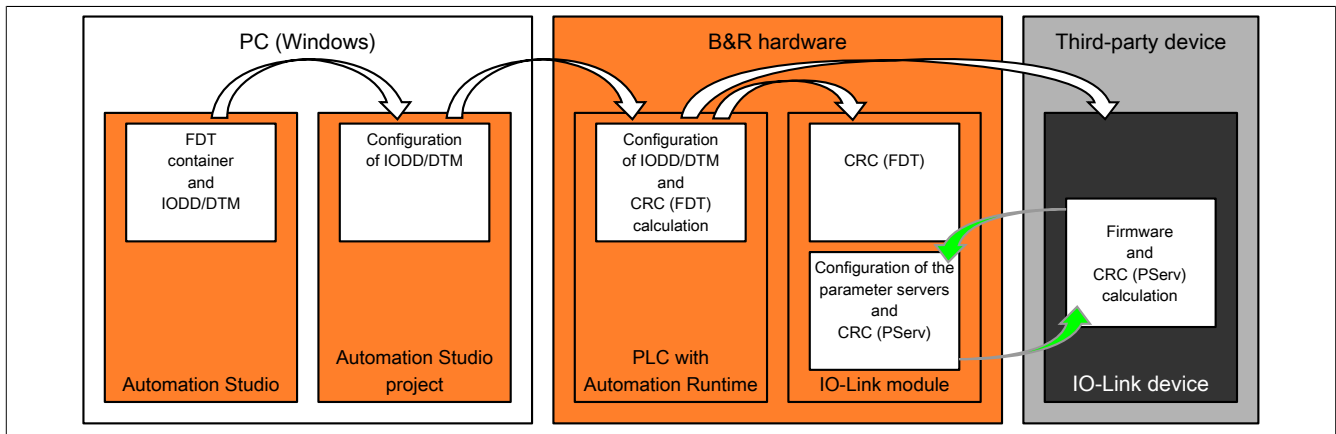

Procedure

- 1) If the IO-Link device supports the function "parameter server", on startup it calculates the checksum ($CRC_{P_{Serv}}$) for its current parameter set.
- 2) If the currently calculated checksum ($CRC_{P_{Serv}}$) deviates from the one previously stored on the IO-Link module, then there is a difference between the parameter set of the IO-Link device and the one currently stored on the module.
- 3) The device ID and serial number of the IO-Link device are evaluated in order to determine whether the parameter set must be uploaded by the device or downloaded by the IO-Link module.
 - a) If the device ID has been changed, then a different device type was recognized. In this case, the parameter set of the IO-Link device must be read out and saved on the IO-Link module. In addition, the current checksum ($CRC_{P_{Serv}}$) is stored on the IO-Link module.
 - b) If the device ID is unchanged but the serial number is different, it is assumed that the IO-Link device was replaced by a device of the same type. In this case, the parameter set stored on the IO-Link module is downloaded to the IO-Link device.
 - c) If the device ID and serial number remain unchanged, it is assumed that a new configuration has been loaded on the IO-Link device. In this case, the new parameter set on the IO-Link device is read out and saved on the IO-Link module. In addition, the current checksum ($CRC_{P_{Serv}}$) is stored on the IO-Link module.

9.26.15.10.12.4 Shared use of IODD/DTM and parameter server

IODD/DTM support and the parameter server can be used together. The two functions work independently of one another, but they also affect each other.

Changing the configuration using IODD/DTM support

If the IO-Link device is reconfigured using the FDT container (IODD/DTM), the IO-Link device then calculates the new checksum (CRC_{PServ}). Afterwards, the modified data is read back by the parameter server of the IO-Link module.

Replacing the IO-Link device

If the IO-Link device is replaced, the system only checks the checksum (CRC_{PServ}). The parameter set of the FDT container goes unnoticed because the checksum (CRC_{FDT}) in the project on the controller still matches the stored checksum (CRC_{FDT}) on the IO-Link module (for the sequence, see "[Parameter server](#)" on page 3319).

9.26.15.10.13 Error codes

Queries can be made via registers or FlatStream. If a query fails, the error bit is set and an error code generated. In addition to general error codes, vendor-specific error codes can also occur. Information about these can be found in the operating instructions for the corresponding IO-Link device.

Error indicators in the registers

- The error bit is set in "ParameterCtrlIn" on page 3323, whereas the length of the error code is indicated in the data length parameter.
- "ParameterDataIn" on page 3323 contains the error code.

Error indicators in FlatStream

If the error bit is set, the FlatStream bytes are put together as follows:

- Bytes 1 to 3: Module-specific FlatStream array
- Byte 4: Error code; if 8 (error reported by device), bytes 5 and 6 will include additional information.
- Bytes 5 and 6: Error code from IO-Link device
- ...

Error codes

| Code | Function |
|------|---|
| 1 | No device on this channel |
| 2 | IO-Link disabled |
| 3 | Communication error with device |
| 4 | Query buffer full |
| 5 | Event queue empty |
| 6 | Query not supported |
| 7 | Object access failed |
| 8 | Object access, error reported by device |
| 9 | Incorrect channel number |
| 10 | Write operation not possible |
| 11 | No input data available |
| 12 | Frame too short |
| 13 | One or more events discarded |
| 14 | Device has no input data |
| 15 | Device has no output data |

9.26.15.10.14 Command interface

The command interface offers the option of accessing the object dictionary of the IO-Link device using the index and subindex. Access is also possible using the AsIOLink library or FlatStream.

Information:

With this interface, up to the first 4 bytes of an object can be read or written.

Procedure for write operation:

- Set the object to be written using "ParameterIndexOut" on page 3322 and "ParameterSubIndexOut" on page 3322.
- Write the data to be written to "ParameterDataOut" on page 3323.
- Set read/write, IF and the sequence number increased by 1 in the "ParameterCtrlOut" on page 3322 register.
- Wait until the sequence acknowledgment in "ParameterCtrlIn" on page 3323 is the same as the sequence number.

Procedure for read operation:

- Set the object to be read using "ParameterIndexOut" on page 3322 and "ParameterSubIndexOut" on page 3322.
- Delete bit 7 in the "ParameterCtrlOut" on page 3322 parameter, set the channel number and increase the sequence number.
- Wait until the sequence acknowledgment in "ParameterCtrlIn" on page 3323 is the same as the sequence number.
- Read the error status from "ParameterCtrlIn" on page 3323. An error is indicated by a set error bit.
- Read the data from "ParameterCtrlIn" on page 3323.

For error-related behavior, see "Error codes" on page 3321.

9.26.15.10.14.1 ParameterIndexOut

Name:

ParameterIndexOut

This register defines the index of the object in the object dictionary that should be accessed.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

9.26.15.10.14.2 ParameterSubIndexOut

Name:

ParameterSubIndexOut

This register defines the subindex of the object in the object dictionary that should be accessed.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.26.15.10.14.3 ParameterCtrlOut

Name:

ParameterCtrlOut

This register defines the type of access to be used.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|--------|-----------------|
| 0 - 1 | Sequence number | 0 to 3 | |
| 2 - 3 | IO-Link channel number | 0 | IF1 (channel 1) |
| | | 1 | IF2 (channel 2) |
| | | 2 | IF3 (channel 3) |
| | | 3 | IF4 (channel 4) |
| 4 - 6 | Data length | 0 to 4 | |
| 7 | Read or write | 0 | Read |
| | | 1 | Write |

9.26.15.10.14.4 ParameterDataOut

Name:

ParameterDataOut_0

This register contains the data that should be written.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.26.15.10.14.5 ParameterCtrlIn

Name:

ParameterCtrlIn

This register monitors the status of the access.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|--------|---|
| 0 - 1 | Sequence confirmation | 0 to 3 | |
| 2 - 3 | IO-Link channel number | 0 | IF1 (channel 1) |
| | | 1 | IF2 (channel 2) |
| | | 2 | IF3 (channel 3) |
| | | 3 | IF4 (channel 4) |
| 4 - 6 | Data length | 0 to 4 | |
| 7 | Error bit | 0 | No error |
| | | 1 | Error, the error code is indicated in "ParameterDataIn" on page 3323. |

9.26.15.10.14.6 ParameterDataIn

Name:

ParameterDataIn_0

After a successful read operation, this register contains the input data. In the event of an error, it contains the error codes.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

Error display

- If the "error code" on page 3321 does not equal 8 (e.g. error reported by device), then the LSB receives the error code.
- If an error is reported by the device, then the error specified by the IO-Link device is also indicated.

| UDINT | | | |
|----------|--------------------|-------------------------------|-----|
| MSB | | | LSB |
| Reserved | IO-Link error code | Additional IO-Link error code | 8 |

9.26.15.10.15 Using IO-Link with FlatStream

With this module, the user has the option of communicating with the connected IO-Link device via FlatStream.

Communication takes place separately with respect to timing, i.e. output data is transferred completely from the CPU to the module and checked. Only then does the module initiate the actual communication with the IO-Link device.

The module acts the same way in the input direction. Messages from the IO-Link device must have been received completely by the X2X module before the FlatStream message is generated and transmitted to the CPU.

9.26.15.10.15.1 General handling of FlatStream

| Input/Output sequence | Rx/Tx bytes | |
|-----------------------|--------------------------|---|
| (unchanged) | Control byte (unchanged) | Payload data for FlatStream (IO-Link information) |

The user has a choice when using FlatStream.

- Using FlatStream as described in "Flatstream communication" on page 3802
- Using library "AsFlatGen" to manage input/output sequences and the Flatstream control bytes automatically.

In both cases, a module-specific array with FlatStream payload data must be created in the application.

9.26.15.10.15.2 IO-Link information for the FlatStream

To be able to use IO-Link communication via FlatStream, you must define an individual array in the application.

The following must be defined for the query in the direction CPU → Module → IO-Link device:

- Module's channel number
- Frame number for the query
- Type of query
- The corresponding IO-Link data must then be attached depending on the query.

The response consists of the following parts:

- The frame number, access type and type of query are repeated.
- The module generates the error bit and manages the confirmation bit.
- The successfully received IO-Link information or corresponding "error code" on page 3321 is then appended.

Module-specific FlatStream array for IO-Link communication

| Bytes | Name | Value | Description |
|-------|----------------------------|----------|--|
| 1 | Channel number | 1 to 4 | |
| 2 | Frame number | 0 to 255 | This number is repeated in the module's response. This allows the later response from the module to be distinctly attributed to the request. |
| 3 | See Byte 3 | x | |
| ... | IO-Link data or error code | | Depends on byte 3 |

Byte 3

| Bit | Description | Value | Information |
|-------|---------------------------------|-------|---|
| 0 - 2 | Type of query | 0 | Access to object dictionary |
| | | 1 | Access to inputs' process data |
| | | 2 | Access to outputs' process data |
| | | 3 | Read individual event |
| | | 4 | Read multiple events |
| | | 5 | Enable event forwarding |
| | | 6 | Disable event forwarding |
| | | 7 | Announcement of automatically forwarded event |
| 3 - 4 | Reserved | - | |
| 5 | Confirm | 0 | Message without query |
| | | 1 | Response to query ¹⁾ |
| 6 | Status bit (for response frame) | 0 | No error |
| | | 1 | Error |
| 7 | Access types | 0 | Read |
| | | 1 | Write |

1) This confirmation bit is additionally set with the response to a query. The response for confirming a query frequently contains additional data that must be processed.

9.26.15.10.15.3 IO-Link data

Depending on the type of query, different IO-Link data results that must be appended to the FlatStream array.

Access to object dictionary

Request

| Bytes | Name | Value | Description |
|----------|--|----------|--|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |
| 4 | High index number | 0 to 255 | Index of the desired IO-Link parameter |
| 5 | Low index number | 0 to 255 | |
| 6 | Subindex number | 0 to 255 | Subindex of the IO-Link parameter |
| 7 to ... | Data | 0 to 255 | Optional, for write operation |

Response

| Bytes | Name | Value | Description |
|----------|--|----------|---|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |
| 4 to ... | Data / "Error code" on page 3321 | 0 to 255 | Omitted if data has been written successfully |

Accessing process data

Request

| Bytes | Name | Value | Description |
|--------|--|----------|-------------------------------|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |
| 4 | Data | 0 to 255 | Optional, for write operation |

Response

| Bytes | Name | Value | Description |
|--------|--|----------|---|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |
| 4 | Data / "Error code" on page 3321 | 0 to 255 | Omitted if data has been written successfully |

Accessing event data

Request

| Bytes | Name | Value | Description |
|--------|--|-------|-------------|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |

Response

| Bytes | Name | Value | Description |
|--------------|--|------------|------------------------------------|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |
| 4 | Event counter - Current | Bit 0 to 3 | Number of attached events |
| | Event counter - Pending | Bit 4 to 7 | Number of pending events |
| 5 | Event 0 – Event qualifier | 0 to 255 | See "EventQualifier" on page 3308. |
| 6 | Event 0 – High event data | 0 to 255 | |
| 7 | Event 0 – Low event data | 0 to 255 | |
| 8 - 10 | Event 1 | | |
| x to (x + 2) | Event n ¹⁾ | | |

1) Applies only if multiple events were queried with byte 3 (bits 0 to 2 = 4). Only 1 event comes with byte 3 (bits 0 to 2 = 3).

or

| Bytes | Name | Value | Description |
|--------|--|----------|-------------|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |
| 4 | "Error code" on page 3321 | 0 to 255 | |

Enable/Disable event forwarding

Request

| Bytes | Name | Value | Description |
|--------|--|-------|-------------|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |

Response

| Bytes | Name | Value | Description |
|--------|--|-------|-------------|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |

or

| Bytes | Name | Value | Description |
|--------|--|----------|-------------|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |
| 4 | "Error code" on page 3321 | 0 to 255 | |

Announcement of forwarded event

After enabling event forwarding, events no longer have to be queried cyclically. The module generates the event as soon as the corresponding event occurs.

Message

| Bytes | Name | Value | Description |
|--------------|--|------------|------------------------------------|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |
| 4 | Event counter - Current | Bit 0 to 3 | Number of attached events |
| | Event counter - Pending | Bit 4 to 7 | Number of pending events |
| 5 | Event 0 – Event qualifier | 0 to 255 | See "EventQualifier" on page 3308. |
| 6 | Event 0 – High event data | 0 to 255 | |
| 7 | Event 0 – Low event data | 0 to 255 | |
| 8 - 10 | Event 1 | | |
| x to (x + 2) | Event n ¹⁾ | | |

1) Applies only if multiple events were queried with byte 3 (bits 0 to 2 = 4). Only 1 event comes with byte 3 (bits 0 to 2 = 3).

OR

| Bytes | Name | Value | Description |
|--------|--|----------|-------------|
| 1 to 3 | Module-specific FlatStream array for IO-Link communication | | |
| 4 | "Error code" on page 3321 | 0 to 255 | |

9.26.15.10.16 Flatstream communication

For a description of Flatstream communication, see "[Flatstream communication](#)" on page 3802

9.26.15.10.17 NetTime Technology

For a description of NetTime Technology, see "[NetTime Technology](#)" on page 3035.

9.26.15.10.18 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|---|---------|
| Without IO-Link (all channels in SIO-Modus) | ≥200 µs |
| With IO-Link | ≥400 µs |

9.26.15.10.19 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|---|---|
| Without IO-Link (all channels in SIO-Modus) | ≥200 µs |
| With IO-Link | ≥400 µs (depends on the minimum IO-Link cycle time of the IO-Link device) |

9.26.16 X20PD0011

Data sheet version: 3.13

9.26.16.1 General information

The potential distributor module provides 12x ground (from the internal I/O supply) on the terminal connections and opens up additional wiring possibilities for actuators and sensors. The module is equipped with a replaceable microfuse between the GND potential on the terminal block and the X20 system I/O supply. The function of the fuse is monitored.

- Integrated exchangeable microfuse
- Monitoring of the fuse
- Potential for routing as needed

Information:

The wired load must be supplied with 24 VDC!

9.26.16.2 Order data

| Model number | Short description | Figure |

- 1) The specified values are maximum values. For examples of the exact calculation, see section "Mechanical and electrical configuration" of the X20 system user's manual.

9.26.16.4 LED status indicators

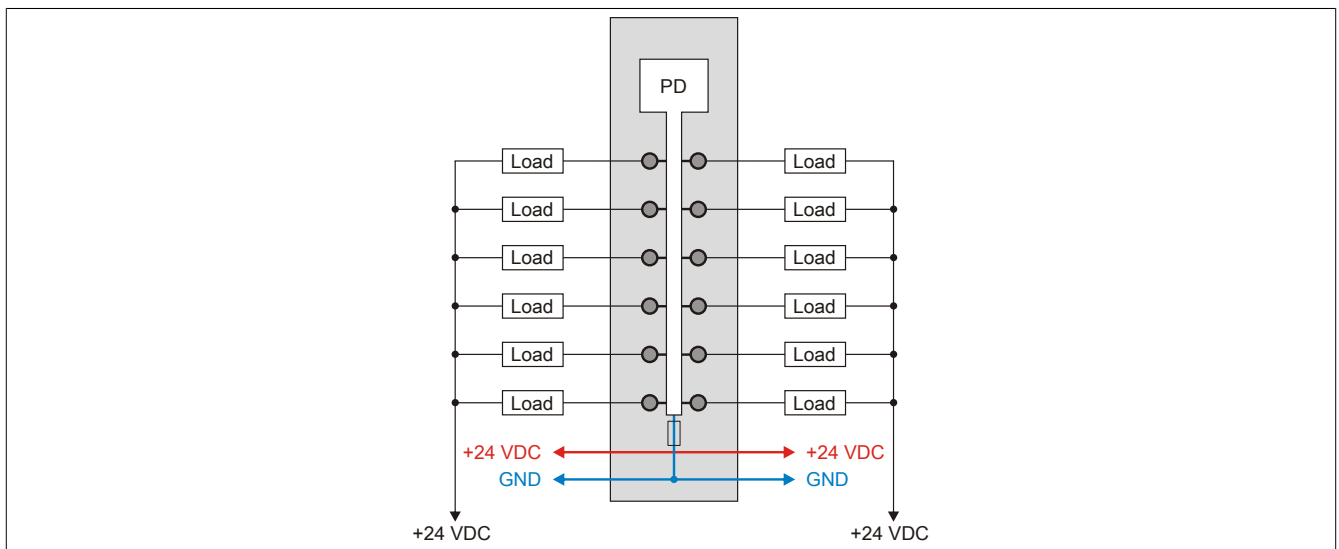

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-------|-----------------------------|-------------------------------------|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Single flash | Fuse defective or missing |
| | e + r | | Red on / Green single flash | Invalid firmware |

9.26.16.5 Pinout

9.26.16.6 Connection example

9.26.16.7 Replacing the built-in fuse

The module is equipped with a 6.3 A built-in fuse. Proceed as follows to replace a defective fuse:

- 1) Remove the fuse cover with the fuse on the right side of the module using a screwdriver.
- 2) Slide the cylindrical fuse out of the fuse holder and slide the new fuse in.

9.26.16.8 Register description

9.26.16.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.26.16.8.2 Function model 1 - Standard

| Register | Fixed offset | Name | Data type | Read | | Write | |
|----------|--------------|---------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 1 | Module status | USINT | • | | | |
| | | StatusFuse | Bit 0 | | | | |

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Non-cyclic access continues to be based on the register numbers.

9.26.16.8.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|---------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 0 | Module status | USINT | • | | | |
| | | StatusFuse | Bit 0 | | | | |

1) The offset specifies the position of the register within the CAN object.

9.26.16.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.16.8.3.2 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN I/O.

9.26.16.8.4 Module status

Name:
Module status
StatusFuse

This register can be used to read the status of the installed fuse.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-------------|
| 0 | StatusFuse | 0 | Fuse OK |
| | | 1 | Fuse not OK |
| 1 - 7 | Reserved | - | |

9.26.16.8.5 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 µs |

9.26.16.8.6 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 100 µs |

9.26.17 X20PD0012

Data sheet version: 3.13

9.26.17.1 General information

The potential distributor module provides 12x 24 VDC (from the internal I/O supply) on the terminal connections and opens up additional wiring possibilities for actuators and sensors. The module is equipped with a replaceable microfuse between the 24 VDC potential on the terminal block and the X20 system I/O supply. The function of the fuse is monitored.

- Integrated exchangeable microfuse
- Monitoring of the fuse
- Potential for routing as needed

9.26.17.5 Pinout

9.26.17.6 Connection example

9.26.17.7 Replacing the built-in fuse

The module is equipped with a 6.3 A built-in fuse. Proceed as follows to replace a defective fuse:

- 1) Remove the fuse cover with the fuse on the right side of the module using a screwdriver.
- 2) Slide the cylindrical fuse out of the fuse holder and slide the new fuse in.

9.26.17.8 Register description

9.26.17.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.26.17.8.2 Function model 1 - Standard

| Register | Fixed offset | Name | Data type | Read | | Write | |
|----------|--------------|---------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 1 | Module status | USINT | • | | | |
| | | StatusFuse | Bit 0 | | | | |

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Non-cyclic access continues to be based on the register numbers.

9.26.17.8.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|---------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 0 | Module status | USINT | • | | | |
| | | StatusFuse | Bit 0 | | | | |

1) The offset specifies the position of the register within the CAN object.

9.26.17.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.17.8.3.2 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN I/O.

9.26.17.8.4 Module status

Name:
Module status
StatusFuse

This register can be used to read the status of the installed fuse.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-------------|
| 0 | StatusFuse | 0 | Fuse OK |
| | | 1 | Fuse not OK |
| 1 - 7 | Reserved | - | |

9.26.17.8.5 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 µs |

9.26.17.8.6 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 100 µs |

9.26.18 X20PD0016

Data sheet version: 3.13

9.26.18.1 General information

The potential distributor module provides 5x 24 VDC and 5x ground connections (from an external supply) at the terminals. There is no connection to the internal I/O supply, so this module only serves to distribute an external supply for the load and electronics supply. The externally fed 24 VDC supply is provided on the terminal connections through a replaceable microfuse. The 24 VDC feed and the functionality of the fuse are monitored.

- Integrated exchangeable microfuse
- Monitoring of the fuse
- Potential for routing as needed
- Distribution of the load and electronics supply
- Isolation from the internal I/O supply

9.26.18.2 Order data

| Model number | Short description | Figure |
|--------------|---|--|

| | | | Double flash | Supply voltage too low |
| | e + r | | Red on / Green single flash | Invalid firmware |

9.26.18.5 Pinout

9.26.18.6 Connection example

9.26.18.7 Replacing the built-in fuse

The module is equipped with a 6.3 A built-in fuse. Proceed as follows to replace a defective fuse:

- 1) Remove the fuse cover with the fuse on the right side of the module using a screwdriver.
- 2) Slide the cylindrical fuse out of the fuse holder and slide the new fuse in.

9.26.18.8 Register description

9.26.18.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.26.18.8.2 Function model 1 - Standard

| Register | Fixed offset | Name | Data type | Read | | Write | |
|----------|--------------|-------------------------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 1 | Module status | USINT | • | | | |
| | | StatusFuse | Bit 0 | | | | |
| | | StatusPowerSupply | Bit 1 | | | | |
| 2 | 2 | Counter01 | USINT | • | | | |

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Non-cyclic access continues to be based on the register numbers.

9.26.18.8.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|-------------------------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 0 | Module status | USINT | • | | | |
| | | StatusFuse | Bit 0 | | | | |
| | | StatusPowerSupply | Bit 1 | | | | |
| 2 | 2 | Counter01 | USINT | • | | | |

1) The offset specifies the position of the register within the CAN object.

9.26.18.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.18.8.3.2 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN I/O.

9.26.18.8.4 Module status

Name:

Module status

StatusFuse

StatusPowerSupply

This register can be used to read the status of the power supply.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------------|-------|-----------------------------|
| 0 | StatusFuse | 0 | Fuse OK |
| | | 1 | Fuse not OK |
| | StatusPowerSupply | 0 | Level of fed voltage OK |
| | | 1 | Level of fed voltage not OK |
| 2 - 7 | Reserved | - | |

9.26.18.8.5 Counter for the voltage dips

Name:

Counter01

This register is used to count how often the voltage dips on the PD module.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.26.18.8.6 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 μ s |

9.26.18.8.7 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 100 μ s |

9.26.19 X20(c)PD2113

Data sheet version: 3.23

9.26.19.1 General information

The potential distributor module with feed can provide 6x 24 VDC and 6x ground connections from the internal I/O supply on the terminals. This module can also be used instead of a special feed module for the internal I/O supply. The internal 24 VDC supply is connected to the terminal connections through a replaceable microfuse for protection. The 24 VDC feed and the functionality of the fuse are monitored.

Information:

Since the 6x 24 VDC terminals are interconnected and the fuse is located between the terminals and the internal I/O supply, the terminal potentials are not protected against short circuits from an external feed. If using an external feed, the respective 24 VDC terminals must be protected with an external fuse. In this case a X20BM01 bus module should be used.

- Integrated exchangeable microfuse
- Monitoring of the fuse
- Potential for routing as needed
- Can be used as feed module for the I/O supply

9.26.19.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.26.19.3 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | Other functions |  |
| X20PD2113 | X20 potential distributor module, 6x GND, 6x 24 VDC, with feed option, integrated microfuse | |

9.26.19.5 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

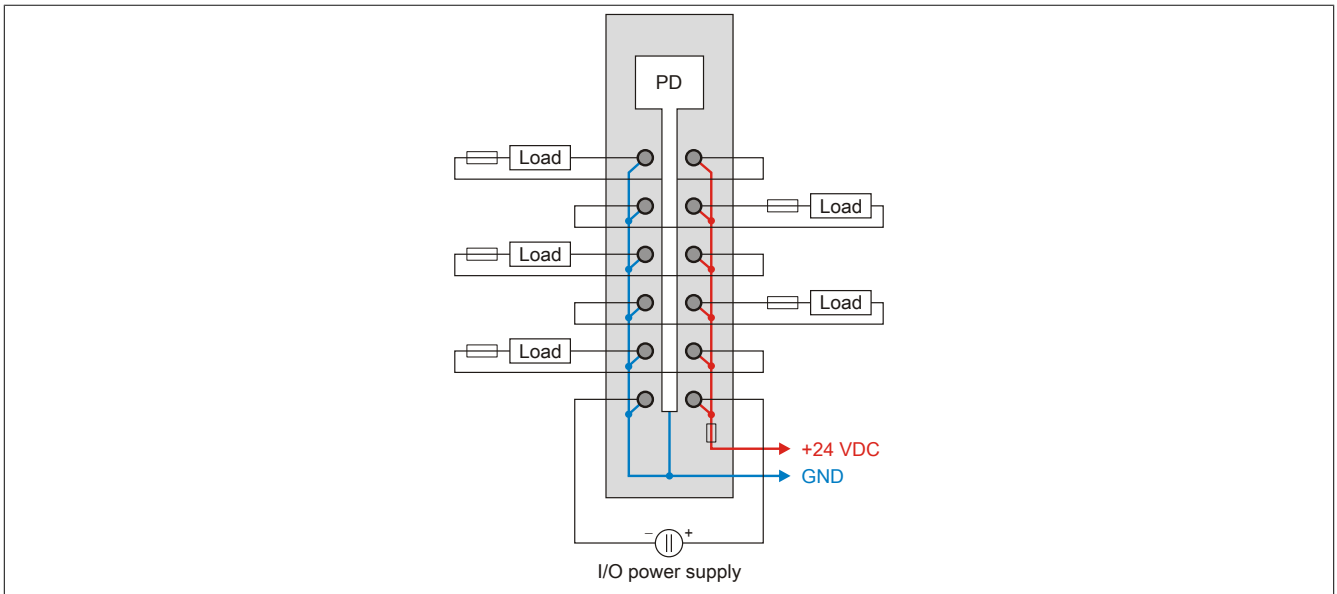

| Figure | LED | Color | Status | Description | |
|---|-------|-------|-----------------------------|-------------------------------------|--|
|  | r | Green | Off | No power to module | |
| | | | Single flash | RESET mode | |
| | | | Blinking | PREOPERATIONAL mode | |
| | | | On | RUN mode | |
| | e | Red | Off | No power to module or everything OK | |
| | | | On | Error or reset status | |
| | | | Single flash | Fuse defective or missing | |
| | | | Double flash | Supply voltage too low | |
| | e + r | | Red on / Green single flash | Triple flash | Internal I/O supply OK but fuse defective and supply voltage too low |
| | | | | | Invalid firmware |

9.26.19.6 Pinout

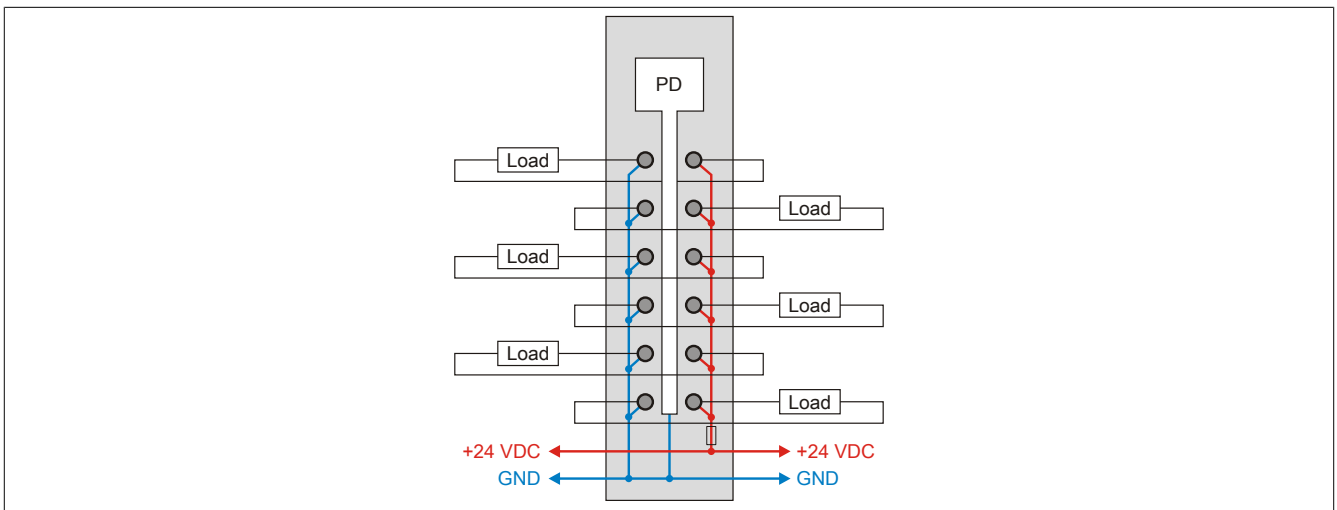

9.26.19.7 Connection examples

Connection example with external supply

Connection example with internal supply

9.26.19.8 Replacing the built-in fuse

The module is equipped with a 6.3 A built-in fuse. Proceed as follows to replace a defective fuse:

- 1) Remove the fuse cover with the fuse on the right side of the module using a screwdriver.
- 2) Slide the cylindrical fuse out of the fuse holder and slide the new fuse in.

9.26.19.9 Register description

9.26.19.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.26.19.9.2 Function model 1 - Standard

| Register | Fixed offset | Name | Data type | Read | | Write | |
|----------|--------------|-------------------------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 1 | Module status | USINT | • | | | |
| | | StatusFuse | Bit 0 | | | | |
| | | StatusPowerSupply | Bit 1 | | | | |
| 2 | 2 | Counter01 | USINT | • | | | |

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Non-cyclic access continues to be based on the register numbers.

9.26.19.9.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|-------------------------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 0 | Module status | USINT | • | | | |
| | | StatusFuse | Bit 0 | | | | |
| | | StatusPowerSupply | Bit 1 | | | | |
| 2 | 2 | Counter01 | USINT | • | | | |

1) The offset specifies the position of the register within the CAN object.

9.26.19.9.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.19.9.3.2 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN I/O.

9.26.19.9.4 Module status

Name:

Module status

StatusFuse

StatusPowerSupply

This register can be used to read the status of the power supply.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------------|-------|-----------------------------|
| 0 | StatusFuse | 0 | Fuse OK |
| | | 1 | Fuse not OK |
| | StatusPowerSupply | 0 | Level of fed voltage OK |
| | | 1 | Level of fed voltage not OK |
| 2 - 7 | Reserved | - | |

9.26.19.9.5 Counter for the voltage dips

Name:

Counter01

This register is used to count how often the voltage dips on the PD module.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.26.19.9.6 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 μ s |

9.26.19.9.7 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 100 μ s |

9.26.20 X20PS4951

Data sheet version: 3.14

9.26.20.1 General information

In order to connect potentiometers, modules must first be supplied with the appropriate voltage. The potentiometer supply module can be used to supply four potentiometers with ± 10 V. The data is evaluated using standard analog input modules.

- Open circuit and short circuit detection
- Simple implementation of potentiometer inputs
- 4x supply

9.26.20.2 Order data

| Model number | Short description | Figure |
|--------------|---|--|
| | Other functions |  |
| X20PS4951 | X20 power supply module, for potentiometers, 4x ± 10 V for potentiometer supply | |

9.26.20.9 Register description

9.26.20.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.26.20.9.2 Function model 0 - Standard

| Register | Name | Data type | Read | | Write | |
|----------|-------------------------------|-----------|--------|------------|--------|------------|
| | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | Supply status | USINT | • | | | |
| | ShortCircuit01 | Bit 0 | | | | |
| | ... | ... | | | | |
| | ShortCircuit01 | Bit 3 | | | | |
| | OpenLine01 | Bit 4 | | | | |
| | ... | ... | | | | |
| | OpenLine04 | Bit 7 | | | | |

9.26.20.9.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|-------------------------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 0 | Supply status | USINT | • | | | |
| | | ShortCircuit01 | Bit 0 | | | | |
| | | ... | ... | | | | |
| | | ShortCircuit01 | Bit 3 | | | | |
| | | OpenLine01 | Bit 4 | | | | |
| | | ... | ... | | | | |
| | | OpenLine04 | Bit 7 | | | | |

1) The offset specifies the position of the register within the CAN object.

9.26.20.9.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.20.9.3.2 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN I/O.

9.26.20.9.4 Supply status

Name:

OpenLine01 to OpenLine04

ShortCircuit01 to ShortCircuit04

This register can be used to display the status of the respective channels.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------|-------|----------------------------|
| 0 | ShortCircuit01 | 0 | No short circuit |
| | | 1 | Short circuit on channel 1 |
| ... | ... | ... | ... |
| 3 | ShortCircuit04 | 0 | No short circuit |
| | | 1 | Short circuit on channel 4 |
| 4 | OpenLine01 | 0 | No open line |
| | | 1 | Open line on channel 1 |
| ... | ... | ... | ... |
| 7 | OpenLine04 | 0 | No open line |
| | | 1 | Open line on channel 4 |

9.26.20.9.5 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 μ s |

9.26.20.9.6 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 1 ms |

9.27 Power supply modules

The internal I/Os and the X2X Link are fed by the supply modules.

9.27.1 Summary

| Model number | Short description | Page |
|--------------|--|------|
| X20PS2100 | X20 power supply module, for internal I/O supply | 3356 |
| X20PS2110 | X20 power supply module, for internal I/O power supply, integrated microfuse | 3361 |
| X20PS3300 | X20 power supply module, for X2X Link and internal I/O power supply | 3367 |

| X20cPS3310 | X20 power supply module, coated, for X2X Link and internal I/O power supply integrated microfuse | 3373 |

9.27.2 X20(c)PS2100

Data sheet version: 3.17

9.27.2.1 General information

The supply module is used for the internal I/O supply.

- 24 VDC supply module for internal I/O supply

9.27.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.27.2.3 Order data

| e + r | | Red on / Green single flash | Invalid firmware | |

9.27.2.6 Pinout

9.27.2.7 Connection example

9.27.2.8 Safe shutdown of potential group

In safety-related applications, it must be guaranteed that the potential group is safely shut down in order to achieve a category 4 shutdown in accordance with EN ISO 13849-1. An X20PS2100 (rev.F0 or higher) or X20PS2110 (rev.C0 or higher) supply module must be used to do this.

For important notes concerning "safe shutdown", see section "Mechanical and electrical configuration" of the X20 system user's manual. The user's manual can be downloaded from the Downloads section of the B&R website (www.br-automation.com).

9.27.2.9 Register description

9.27.2.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.27.2.9.2 Function model 0 - Standard

| Register | Fixed offset | Name | Data type | Read | | Write | |
|----------|--------------|-------------------------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 1 | Module status | USINT | • | | | |
| | | StatusInput01 | Bit 0 | | | | |
| | | StatusInput02 | Bit 2 | | | | |
| 4 | 3 | SupplyVoltage | USINT | • | | | |

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

9.27.2.9.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|-------------------------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| 0 | 0 | Module status | UINT | • | | | |
| | | StatusInput01 | Bit 0 | | | | |
| | | StatusInput02 | Bit 2 | | | | |
| 4 | 4 | SupplyVoltage | UINT | • | | | |

1) The offset specifies the position of the register within the CAN object.

9.27.2.9.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.27.2.9.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.27.2.9.4 Module status

Name:

Module status

The following module supply voltages are monitored in this register:

Bus supply voltage: Bus supply voltage <4.7 V is displayed as a warning.

24 VDC I/O supply voltage: I/O supply voltage <20.4 V is displayed as a warning.

| Function model | Data type | Values |
|----------------------|-----------|------------------------|
| 0 - Standard | USINT | See the bit structure. |
| 254 - Bus controller | UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|---------------|-------|--|
| 0 | StatusInput01 | 0 | No error |
| | | 1 | Bus supply warning - Undervoltage (<4.7 V) |
| 1 | Reserved | 0 | |
| 2 | StatusInput02 | 0 | I/O power supply above the warning limit of 20.4 V |
| | | 1 | I/O power supply below the warning limit of 20.4 V |
| 3 - x | Reserved | 0 | |

9.27.2.9.5 Bus supply voltage

Name:

SupplyVoltage

This register indicates the bus supply voltage measured at a resolution of 0.1 V.

| Function model | Data type |
|----------------------|-----------|
| 0 - Standard | USINT |
| 254 - Bus controller | UINT |

9.27.2.9.6 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 μ s |

9.27.2.9.7 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 2 ms |

9.27.3 X20(c)PS2110

Data sheet version: 3.26

9.27.3.1 General information

The power supply module is used for the internal I/O power supply. The module has an integrated replaceable fuse for the I/O power supply.

- 24 VDC supply module for internal I/O supply
- Fuse for I/O power supply integrated in module

9.27.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.27.3.3 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | Power supplies |  |
| X20PS2110 | X20 power supply module, for internal I/O power supply, integrated microfuse | |
| X20cPS2110 | X20 power supply module, coated, for internal I/O power supply, integrated microfuse | |
| | Required accessories | |

Table 578: X20PS2110, X20cPS2110 - Technical data

- 1) The specified values are maximum values. For examples of the exact calculation, see section "Mechanical and electrical configuration" of the X20 system user's manual.

9.27.3.5 LED status indicators

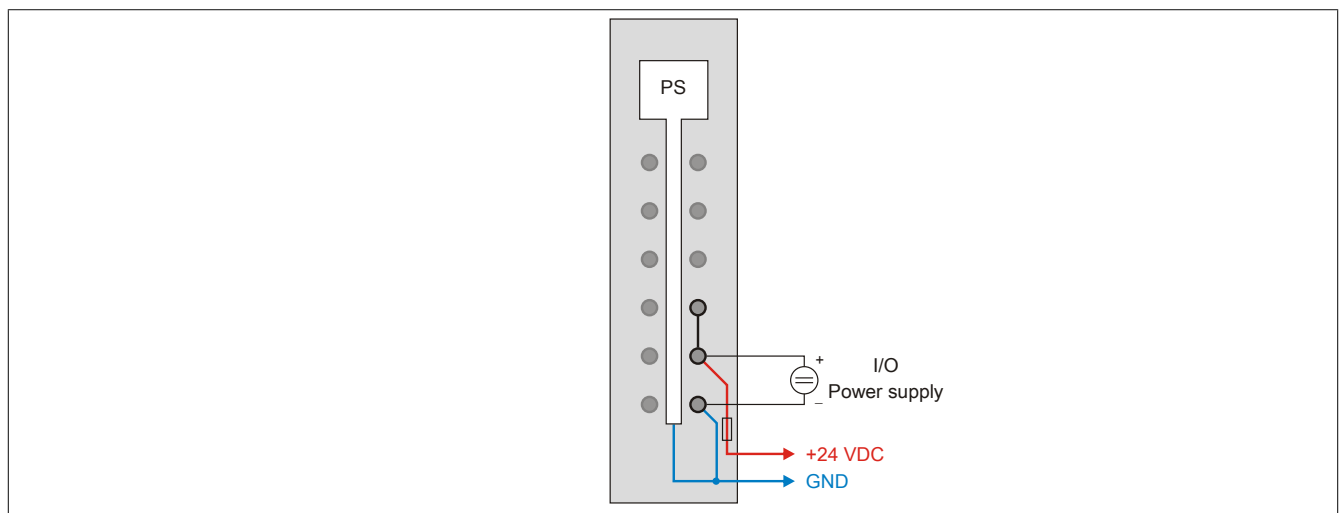

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-----|-----------------------------|------------------|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Double flash | LED indicates one of the following states: <ul style="list-style-type: none"> • I/O power supply too low • X2X Link voltage too low |
| e + r | | Red on / green single flash | Invalid firmware | |

9.27.3.6 Pinout

9.27.3.7 Connection example

9.27.3.8 Safe shutdown of potential group

In safety-related applications, it must be guaranteed that the potential group is safely shut down in order to achieve a category 4 shutdown in accordance with EN ISO 13849-1. An X20PS2100 (rev.F0 or higher) or X20PS2110 (rev.C0 or higher) supply module must be used to do this.

For important notes concerning "safe shutdown", see section "Mechanical and electrical configuration" of the X20 system user's manual. The user's manual can be downloaded from the Downloads section of the B&R website (www.br-automation.com).

9.27.3.9 Replacing the built-in fuse

The module is equipped with a 6.3 A built-in fuse. Proceed as follows to replace a defective fuse:

- 1) Remove the fuse cover with the fuse on the right side of the module using a screwdriver.
- 2) Slide the cylindrical fuse out of the fuse holder and slide the new fuse in.

9.27.3.10 Register description

9.27.3.10.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.27.3.10.2 Function model 0 - Standard

| Register | Fixed offset | Name | Data type | Read | | Write | |
|----------|--------------|----------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 0 | 1 | Status of the module | USINT | • | | | |
| | | StatusInput01 | Bit 0 | | | | |
| | | StatusInput02 | Bit 1 | | | | |
| | | StatusInput03 | Bit 2 | | | | |
| 4 | 3 | SupplyVoltage | USINT | • | | | |

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

9.27.3.10.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|----------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 0 | 0 | Status of the module | UINT | • | | | |
| | | StatusInput01 | Bit 0 | | | | |
| | | StatusInput02 | Bit 1 | | | | |
| | | StatusInput03 | Bit 2 | | | | |
| 4 | 4 | SupplyVoltage | UINT | • | | | |

1) The offset specifies the position of the register within the CAN object.

9.27.3.10.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.27.3.10.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.27.3.10.4 Status of the module

Name:

Module status

The following module supply voltages are monitored in this register:

| | |
|----------------------------|--|
| Bus supply voltage: | A bus supply voltage of <4.7 V is displayed as a warning. |
| 24 VDC I/O supply voltage: | An I/O supply voltage of <20.4 V is displayed as a warning. |
| Safety status: | Applies to hardware revision C0 and later. When using modules <C0, a defective fuse is not detected! |

| Function model | Data type | Values |
|----------------------|-----------|------------------------|
| 0 - Standard | USINT | See the bit structure. |
| 254 - Bus controller | UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|---------------|-------|--|
| 0 | StatusInput01 | 0 | No error |
| | | 1 | Bus supply warning - Undervoltage (<4.7 V) |
| 1 | StatusInput02 | 0 | Fuse OK or hardware revision <C0 |
| | | 1 | Fuse defective |
| 2 | StatusInput03 | 0 | I/O power supply above the warning threshold of 20.4 V |
| | | 1 | I/O power supply below the warning threshold of 20.4 V |
| 3 - x | Reserved | 0 | |

9.27.3.10.5 Bus supply voltage

Name:

SupplyVoltage

This register indicates the bus supply voltage measured at a resolution of 0.1 V.

| Function model | Data type |
|----------------------|-----------|
| 0 - Standard | USINT |
| 254 - Bus controller | UINT |

9.27.3.10.6 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 μ s |

9.27.3.10.7 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 2 ms |

9.27.4 X20(c)PS3300

Data sheet version: 3.17

9.27.4.1 General information

The supply module is equipped with a feed for the X2X Link as well as the internal I/O supply.

- Feed for X2X Link and internal I/O supply
- Electrical isolation of feed and X2X Link supply
- Redundancy of X2X Link supply possible by operating multiple supply modules simultaneously

9.27.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.27.4.3 Order data

| Model number | Short description | Figure |
|--------------|---|--------|

Table 580: X20PS3300, X20cPS3300 - Technical data

- 1) The specified values are maximum values. For examples of the exact calculation, see section "Mechanical and electrical configuration" of the X20 system user's manual.
- 2) In parallel operation, only 75% of the rated power can be assumed. It is important to make sure that all power supplies operated in parallel are switched on and off at the same time.

9.27.4.5 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-------|--|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Double flash | LED indicates one of the following states: <ul style="list-style-type: none"> • The X2X Link supply for the power supply is overloaded • I/O supply too low • Input voltage for X2X Link supply too low |
| | e + r | | Red on / Green single flash | Invalid firmware |
| l | Red | Off | The X2X Link supply is within the valid limits | |
| | | On | The X2X Link supply for the power supply is overloaded | |

9.27.4.6 Pinout

9.27.4.7 Connection examples

With 2 isolated power supplies

With 1 power supply and jumper

9.27.4.8 Derating

The nominal output power for the power supply is 7 W. Depending on the mounting orientation, derating must be taken into account.

9.27.4.9 Register description

9.27.4.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.27.4.9.2 Function model 0 - Standard

| Register | Fixed offset | Name | Data type | Read | | Write | |
|----------|--------------|----------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 0 | 1 | Status of the module | USINT | • | | | |
| | | StatusInput01 | Bit 0 | | | | |
| | | StatusInput02 | Bit 2 | | | | |
| 2 | 2 | SupplyCurrent | USINT | • | | | |
| 4 | 3 | SupplyVoltage | USINT | • | | | |

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

9.27.4.9.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|----------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 0 | 0 | Status of the module | UINT | • | | | |
| | | StatusInput01 | Bit 0 | | | | |
| | | StatusInput02 | Bit 2 | | | | |
| 2 | 2 | SupplyCurrent | UINT | • | | | |
| 4 | 4 | SupplyVoltage | UINT | • | | | |

1) The offset specifies the position of the register within the CAN object.

9.27.4.9.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "[Using I/O modules on the bus controller](#)" on page 3789.

9.27.4.9.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.27.4.9.4 Status of the module

Name:

Module status

The following voltage and current states of the module are monitored in this register:

| | |
|----------------------------|--|
| Bus power supply current: | Bus power supply current >2.3 A is displayed as a warning. |
| Bus supply voltage: | Bus supply voltage <4.7 V is displayed as a warning. |
| 24 VDC I/O supply voltage: | I/O supply voltage <20.4 V is displayed as a warning. |

| Function model | Data type | Values |
|----------------------|-----------|------------------------|
| 0 - Standard | USINT | See the bit structure. |
| 254 - Bus controller | UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------|-------|---|
| 0 | StatusInput01 | 0 | No error |
| | | 1 | Warning in the event of overcurrent (>2.3 A) or undervoltage (<4.7 V) |
| 1 | Reserved | 0 | |
| 2 | StatusInput02 | 0 | I/O power supply above the warning limit of 20.4 V |
| | | 1 | I/O power supply below the warning limit of 20.4 V |
| 3 - x | Reserved | 0 | |

9.27.4.9.5 Bus power supply current

Name:
SupplyCurrent

This register displays the bus power supply current measured at a resolution of 0.1 A.

| Function model | Data type |
|----------------------|-----------|
| 0 - Standard | USINT |
| 254 - Bus controller | UINT |

9.27.4.9.6 Bus supply voltage

Name:
SupplyVoltage

This register indicates the bus supply voltage measured at a resolution of 0.1 V.

| Function model | Data type |
|----------------------|-----------|
| 0 - Standard | USINT |
| 254 - Bus controller | UINT |

9.27.4.9.7 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 μ s |

9.27.4.9.8 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 2 ms |

9.27.5 X20(c)PS3310

Data sheet version: 3.25

9.27.5.1 General information

The supply module is equipped with a feed for the X2X Link as well as the internal I/O supply. The module has an integrated replaceable fuse for the I/O supply.

- Feed for X2X Link and internal I/O supply
- Electrical isolation of feed and X2X Link supply
- Redundancy of X2X Link supply possible by operating multiple supply modules simultaneously
- Fuse for I/O supply integrated in module

9.27.5.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

Table 582: X20PS3310, X20cPS3310 - Technical data

- 1) The specified values are maximum values. For examples of the exact calculation, see section "Mechanical and electrical configuration" of the X20 system user's manual.
- 2) In parallel operation, only 75% of the rated power can be assumed. It is important to make sure that all power supplies operated in parallel are switched on and off at the same time.

9.27.5.5 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-------|--|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Double flash | LED indicates one of the following states: <ul style="list-style-type: none"> • The X2X Link supply for the power supply is overloaded • I/O supply too low • Input voltage for X2X Link supply too low |
| | e + r | | Red on / Green single flash | Invalid firmware |
| l | Red | Off | The X2X Link supply is within the valid limits | |
| | | On | The X2X Link supply for the power supply is overloaded | |

9.27.5.6 Pinout

9.27.5.7 Connection examples

With 2 separate supplies

With a supply and jumper

9.27.5.8 Derating

The nominal output power for the power supply is 7 W. Depending on the mounting orientation, derating must be taken into account.

9.27.5.9 Replacing the built-in fuse

The module is equipped with a 6.3 A built-in fuse. Proceed as follows to replace a defective fuse:

- 1) Remove the fuse cover with the fuse on the right side of the module using a screwdriver.
- 2) Slide the cylindrical fuse out of the fuse holder and slide the new fuse in.

9.27.5.10 Register description

9.27.5.10.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.27.5.10.2 Function model 0 - Standard

| Register | Fixed offset | Name | Data type | Read | | Write | |
|----------|--------------|----------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 0 | 1 | Status of the module | USINT | • | | | |
| | | StatusInput01 | Bit 0 | | | | |
| | | StatusInput02 | Bit 2 | | | | |
| 2 | 2 | SupplyCurrent | USINT | • | | | |
| 4 | 3 | SupplyVoltage | USINT | • | | | |

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

9.27.5.10.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|----------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 0 | 0 | Status of the module | UINT | • | | | |
| | | StatusInput01 | Bit 0 | | | | |
| | | StatusInput02 | Bit 2 | | | | |
| 2 | 2 | SupplyCurrent | UINT | • | | | |
| 4 | 4 | SupplyVoltage | UINT | • | | | |

1) The offset specifies the position of the register within the CAN object.

9.27.5.10.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.27.5.10.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.27.5.10.4 Status of the module

Name:

Module status

The following voltage and current states of the module are monitored in this register:

| | |
|----------------------------|--|
| Bus power supply current: | Bus power supply current >2.3 A is displayed as a warning. |
| Bus supply voltage: | Bus supply voltage <4.7 V is displayed as a warning. |
| 24 VDC I/O supply voltage: | I/O supply voltage <20.4 V is displayed as a warning. |

| Function model | Data type | Values |
|----------------------|-----------|------------------------|
| 0 - Standard | USINT | See the bit structure. |
| 254 - Bus controller | UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------|-------|---|
| 0 | StatusInput01 | 0 | No error |
| | | 1 | Warning in the event of overcurrent (>2.3 A) or undervoltage (<4.7 V) |
| 1 | Reserved | 0 | |
| 2 | StatusInput02 | 0 | I/O power supply above the warning limit of 20.4 V |
| | | 1 | I/O power supply below the warning limit of 20.4 V |
| 3 - x | Reserved | 0 | |

9.27.5.10.5 Bus power supply current

Name:

SupplyCurrent

This register displays the bus power supply current measured at a resolution of 0.1 A.

| Function model | Data type |
|----------------------|-----------|
| 0 - Standard | USINT |
| 254 - Bus controller | UINT |

9.27.5.10.6 Bus supply voltage

Name:

SupplyVoltage

This register indicates the bus supply voltage measured at a resolution of 0.1 V.

| Function model | Data type |
|----------------------|-----------|
| 0 - Standard | USINT |
| 254 - Bus controller | UINT |

9.27.5.10.7 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 μ s |

9.27.5.10.8 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 2 ms |

9.28 reACTION I/O modules

A number of I/O modules are available featuring ultrafast reACTION technology. This allows the I/O channels integrated in the reACTION module to be controlled with response times down to 1 μ s. This new approach allows extremely time-critical subprocesses to be managed using standard hardware – which lowers hardware costs by reducing the load on the controller and allowing it to be scaled down.

All of the commands that can be used for reACTION programs are provided as function blocks in special libraries (e.g. AsIORTI). Programming using the standard Function Block Diagram (FBD) editor in Automation Studio is compliant with IEC 61131-3.

Documentation for reACTION technology is included in the Automation Studio help system.

9.28.1 Summary

| Model number | Short description | Page |
|---------------|---|------|
| X20CP1381-RT | X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 1 GB onboard flash drive, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100BASE-T, reACTION Technology, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 μ s, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 μ s, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs \pm 10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, includes power supply module, 3x terminal block X20TB1F, slot cover and X20 end cover plate X20AC0SR1 (right) included | 3382 |
| X20CP1382-RT | X20 CPU, with integrated I/O, x86-400, 256 MB DDR3 RAM, 32 kB FRAM, 2 GB onboard flash drive, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100BASE-T, reACTION Technology, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 μ s, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 μ s, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs \pm 10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, includes power supply module, 3x terminal block X20TB1F, slot cover and X20 end cover plate X20AC0SR1 (right) included | 3382 |
| X20RT8001 | X20 reACTION module, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, reACTION Technology module | 3448 |
| X20RT8201 | X20 reACTION module, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, 2 analog inputs \pm 10 V, 500 kHz sampling frequency, 13-bit converter resolution including sign, configurable input filter, reACTION Technology module | 3477 |
| X20RT8202 | X20 reACTION module, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, 2 analog outputs \pm 10 V, 2 μ s, 13-bit converter resolution including sign, reACTION Technology module | 3511 |
| X20RT8381 | X20 reACTION module, real computing function, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, 2 analog inputs \pm 10 V, 500 kHz sampling frequency, 13-bit converter resolution including sign, configurable input filter, 1 analog output \pm 10 V, 2 μ s, 13-bit converter resolution including sign, reACTION Technology module | 3543 |
| X20RT8401 | X20 reACTION module, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, 1 analog input \pm 10 V, 500 kHz sampling frequency, 13-bit converter resolution including sign, configurable input filter, 1 analog output \pm 10 V, 2 μ s, 13-bit converter resolution including sign, reACTION Technology module | 3577 |
| X20cCP1382-RT | X20 CPU, coated with integrated I/O, x86-400, 256 MB DDR3 RAM, 32 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, reACTION Technology, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 μ s, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 μ s, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs \pm 10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 end cover plate (right) included | 3382 |

9.28.2 X20CP1381-RT and X20(c)CP1382-RT

Data sheet version: 1.23

9.28.2.1 General information

Compact CPUs are available with processor speeds of 200 MHz and 400 MHz. Depending on the variant, up to 256 MB RAM and up to 32 kB nonvolatile onboard RAM is available. A built-in flash drive is available to store up to 2 GB of application and other data.

These CPUs come equipped with POWERLINK, Ethernet, CAN bus, 2x USB and one RS232 interface. If additional fieldbus connections are needed, the CPU can be upgraded with an interface module from the standard X20 product range. These CPUs do not require fans or batteries and are therefore maintenance-free. 30 different digital inputs and outputs and 2 analog inputs are integrated in the devices. 1 analog input can be used for PT1000 resistance temperature measurement.

The CPUs are equipped with the new, ultrafast reACTION Technology. All integrated I/O channels are reACTION-capable and can be operated by the reACTION program. These I/O channels are controlled with a response time up to 1 μ s. All of the commands that can be used for reACTION programs are provided as function blocks in special libraries (e.g. AsIORTI). Programming using the standard Function Block Diagram (FBD) editor in Automation Studio is compliant with IEC 61131-3.

- CPU is Intel x86 200/400 MHz compatible with integrated I/O processor
- Ethernet, POWERLINK with poll-response chaining and USB onboard
- 1 slot for modular interface expansion
- Onboard reACTION Technology
- 30 digital inputs/outputs and 2 analog inputs integrated in the device
- 1/2 GB flash drive onboard
- 128/256 MB DDR3 SDRAM
- Fanless
- No battery
- Battery-backed real-time clock

9.28.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.28.2.3 Order data

| Model number | Short description |

| Variant | Connection made using 16-pin X20TB1F terminal block | | |
| Max. distance | 1000 m | | |
| Transfer rate | Max. 1 Mbit/s | | |
| Terminating resistor | Integrated in the module | | |
| Controller | SJA 1000 | | |
| Digital inputs | | | |
| Quantity | 14 standard inputs, 4 high-speed inputs and 4 mixed channels, configurable as inputs or outputs using software | | |
| Nominal voltage | 24 VDC | | |

Table 585: Technical data

| Model number | X20CP1381-RT | X20CP1382-RT | X20cCP1382-RT |
|--|--------------|---|---------------|
| Input voltage | | 24 VDC -15% / +20% | |
| Input current at 24 VDC | | X1 - Standard inputs: Typ. 3.5 mA X2 - Standard inputs: Typ. 2.68 mA X2 - High-speed inputs: Typ. 3.5 mA X3 - Mixed channels: Typ. 2.68 mA | |
| Input circuit | | Sink | |
| Input filter | | | |
| Hardware | | Standard inputs and mixed channels: ≤200 μs High-speed inputs: ≤2 μs, when used as standard inputs: ≤200 μs | |
| Software | | Default 1 ms, configurable between 0 and 25 ms in 0.1 ms intervals | |
| Connection type | | 1-wire connections | |
| Input resistance | | X1 - Standard inputs: 6.8 kΩ X2 - Standard inputs: 8.9 kΩ X2 - High-speed inputs: 6.8 kΩ X3 - Mixed channels: 8.9 kΩ | |
| Additional functions | | X2 - High-speed digital inputs: 2x 250 kHz event counting, 2x AB counter, ABR incremental encoder, direction/frequency, period measurement, gate measurement, differential time measurement, edge counters, edge times | |
| Switching threshold | | | |
| Low | | <5 VDC | |
| High | | >15 VDC | |
| AB incremental encoder | | | |
| Quantity | | 2 | |
| Encoder inputs | | 24 V, asymmetrical | |
| Counter size | | 32-bit | |
| Input frequency | | Max. 100 kHz | |
| Evaluation | | 4x | |
| Encoder power supply | | Module-internal, max. 300 mA | |
| Overload characteristics of encoder power supply | | Short circuit protection, overload protection | |
| ABR incremental encoder | | | |
| Quantity | | 1 | |
| Encoder inputs | | 24 V, asymmetrical | |
| Counter size | | 32-bit | |
| Input frequency | | Max. 100 kHz | |
| Evaluation | | 4x | |
| Encoder power supply | | Module-internal, max. 300 mA | |
| Overload characteristics of encoder power supply | | Short circuit protection, overload protection | |
| Event counters | | | |
| Quantity | | 2 | |
| Signal form | | Square wave pulse | |
| Evaluation | | 1x | |
| Input frequency | | Max. 250 kHz | |
| Counter frequency | | 250 kHz | |
| Counter size | | 32-bit | |
| Edge detection / Time measurement | | | |
| Possible measurements | | Period measurement, gate measurement, differential time measurement, edge counter, edge times | |
| Measurements per module | | Each function up to 2x | |
| Counter size | | 32-bit | |
| Input frequency | | Max. 10 kHz | |
| Timestamp | | 1 μs resolution | |
| Signal form | | Square wave pulse | |
| Analog inputs | | | |
| Input | | ±10 V or 0 to 20 mA / 4 to 20 mA, via different terminal connections | |
| Input type | | Differential input | |
| Digital converter resolution | | | |
| Voltage | | ±12-bit | |
| Current | | 12-bit | |
| Conversion time | | 1 channel enabled: 100 μs 2 channels enabled: 200 μs | |
| Output format | | | |
| Data type | | INT | |
| Voltage | | INT 0x8001 - 0x7FFF / 1 LSB = 0x0008 = 2.441 mV | |
| Current | | INT 0x0000 - 0x7FFF / 1 LSB = 0x0008 = 4.883 μA | |
| Input impedance in signal range | | | |
| Voltage | | 20 MΩ | |
| Current | | - | |
| Load | | | |
| Voltage | | - | |
| Current | | <300 Ω | |
| Input protection | | Protection against wiring with supply voltage | |
| Permissible input signal | | | |
| Voltage | | Max. ±30 V | |
| Current | | Max. ±50 mA | |
| Output of digital value during overload | | Configurable | |

Table 585: Technical data

| Model number | X20CP1381-RT | X20CP1382-RT | X20cCP1382-RT |
|---|--|--------------|---------------|
| Conversion procedure | SAR | | |

| Operation | 5 to 95%, non-condensing | Up to 100%, condensing | |
| Storage | 5 to 95%, non-condensing | | |
| Transport | 5 to 95%, non-condensing | | |
| Mechanical properties | | | |
| Note | X20 end cover plate (right) included in delivery 3 X20 terminal blocks (16-pin) included in delivery Interface module slot cover included in delivery | | |
| Dimensions | | | |
| Width | 164 mm | | |
| Height | 99 mm | | |
| Depth | 75 mm | | |
| Weight | 310 g | | |

Table 585: Technical data

- 1) The specified values are maximum values. For examples of the exact calculation, see section "Mechanical and electrical configuration" of the X20 system user's manual.
- 2) When operated in parallel, the nominal power of 2 W is not permitted to be added to the total power.
- 3) Up to 2 W bus load.
- 4) The size of the memory used for remanent variables is adjustable in Automation Studio.
- 5) See Automation Help under "Communication / POWERLINK / General information / Hardware - IF/LS" for more information.
- 6) Based on the current measured value.
- 7) Based on the 20 V measurement range.
- 8) Based on the 20 mA measurement range.
- 9) Based on the current resistance value.
- 10) Based on the entire resistance measurement range.
- 11) For high-speed digital outputs, derating must be applied at switching frequencies >50 kHz (see section "Switching frequency derating for high-speed digital outputs"). Overtemperature protection is not provided.

- 12) The high-speed digital outputs can be used for pulse width modulation.
 13) Only for standard outputs and mixed channels.
 14) Standard outputs and mixed channels: At loads $\leq 1\text{ k}\Omega$

9.28.2.5 LED status indicators

9.28.2.5.1 Slot X1

| Figure | LED | Color | Status | Description |
|---|---------|-----------|---------------------|---|
|  | E | Red | On | Operating mode SERVICE ¹⁾ or BOOT ¹⁾ |
| | | | Blinking | The "E" LED blinks red and the "RF" LED blinks yellow when there is a license violation. |
| | | | Double flash | Firmware update ²⁾ |
| | R | Green | On | Application running |
| | | | Blinking | System startup: The CPU is initializing the application, all bus systems and I/O modules. ²⁾ |
| | | Red | On | During reset |
| | RF | Yellow | On | Operating mode SERVICE ¹⁾ or BOOT ¹⁾ |
| | | | Blinking | The "RF" LED blinks yellow and the "E" LED blinks red when there is a license violation. |
| | SE | Green/Red | | Status/Error LED. LED states are described in section "LED "S/E" (LED "Status/Error")" on page 3388. |
| | ET | Green | On | A link to the Ethernet remote station has been established. |
| | | | Blinking | A link to the Ethernet remote station has been established. The LED blinks when Ethernet activity is taking place on the bus. |
| | PL | Green | On | A link to the POWERLINK peer station has been established. |
| | | | Blinking | A link to the POWERLINK peer station has been established. The LED blinks when Ethernet activity is taking place on the bus. |
| | A1 - A2 | Green | Off | Open circuit or disconnected sensor |
| | | | Blinking | Input signal overflow or underflow |
| | | | On | Analog/digital converter running, value OK |
| | 1 - 4 | Green | | Input state of the corresponding digital input |
| | C | Yellow | On | CPU transmitting or receiving data via the CAN bus interface |
| | S | Yellow | On | CPU transmitting or receiving data via the RS232 interface |
| | T | Yellow | On | The terminating resistor integrated in the CPU is switched on. |
| DC | Yellow | On | CPU power supply OK | |

Table 586: LED status indicators on the integrated X1 I/O slot

- 1) The operating states are described in Automation Help under "Real-time operating system - Method of operation - Operating states".
 2) The process can take several minutes depending on the configuration.

9.28.2.5.1.1 LED "S/E" (LED "Status/Error")

This LED is a green/red dual LED and indicates the state of the POWERLINK interface. The LED states have a different meaning depending on the operating mode of the POWERLINK interface.

Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

| LED "S/E" | | Description |
|-----------|-----|---|
| Green | Red | |
| On | Off | The interface is operated as an Ethernet interface. |

Table: LED "S/E": Interface in Ethernet mode

POWERLINK V2 mode

Error message

| LED "S/E" | | Description |
|-----------|-----|--|
| Green | Red | |
| Off | On | The interface is in error mode (failed Ethernet frames, increased number of collisions on the network, etc.). Note: Several red blinking signals are displayed immediately after the device is switched on. These are not errors, however. |
| Blinking | On | If an error occurs in the following modes, then the green LED blinks over the red LED: <ul style="list-style-type: none"> • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE |

Table: LED "S/E" - Error message (interface in POWERLINK mode)

Interface status

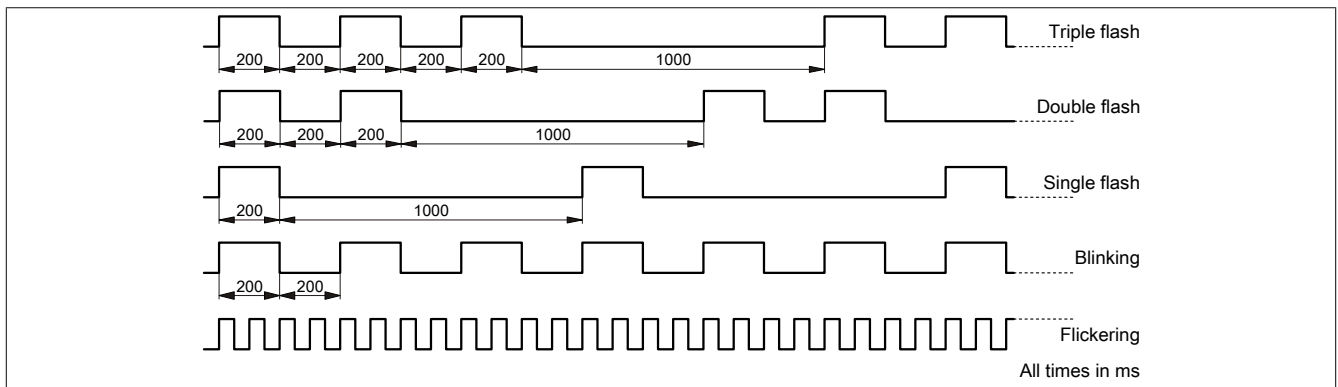

| LED "S/E" | | Description |
|--------------------------------|-----|---|
| Green | Red | |
| Off | Off | Mode: NOT_ACTIVE The interface is either in mode NOT_ACTIVE or one of the following modes or errors is present: <ul style="list-style-type: none"> • The device is switched off. • The device is in the startup phase. • The interface or device is not configured correctly in Automation Studio. • The interface or device is defective. Managing node (MN) The network is monitored for POWERLINK frames. If a frame is not received within the configured time window (timeout), the interface immediately enters mode PRE_OPERATIONAL_1. If POWERLINK communication is detected before the time has elapsed, however, the MN is not started. |
| Flickering (approx. 10 Hz) | Off | Mode: BASIC_ETHERNET The interface is in mode BASIC_ETHERNET. The interface is operated in Ethernet mode . |
| Single flash (approx. 1 Hz) | Off | Mode: PRE_OPERATIONAL_1 The interface is in mode PRE_OPERATIONAL_1. |
| | On | Controlled node (CN) If the red LED lights up in this mode, this means that the MN has failed. |
| Double flash (approx. 1 Hz) | Off | Mode: PRE_OPERATIONAL_2 The interface is in mode PRE_OPERATIONAL_2. |
| | On | Controlled node (CN) If the red LED lights up in this mode, this means that the MN has failed. |

Table: LED "S/E" - Interface state (interface in POWERLINK mode)

| LED "S/E" | | Description |
|--------------------------------|-----|--|
| Green | Red | |
| Triple flash (approx. 1 Hz) | Off | Mode: READY_TO_OPERATE The interface is in mode READY_TO_OPERATE. Managing node (MN) Cyclic and asynchronous communication. Received PDO data is ignored. Controlled node (CN) The configuration of the CN is completed. Normal cyclic and asynchronous communication. The transmitted PDO data corresponds to the PDO mapping. However, cyclic data is not yet evaluated. |
| | On | Controlled node (CN) If the red LED lights up in this mode, this means that the MN has failed. |
| On | Off | Mode: OPERATIONAL The interface is in mode OPERATIONAL. PDO mapping is active and cyclic data is evaluated. |
| Blinking (approx. 2.5 Hz) | Off | Mode: STOPPED The interface is in mode STOPPED. Managing node (MN) This mode does not occur for the MN. Controlled node (CN) Output data is not being output, and no input data is being provided. This mode can only be reached and exited by a corresponding command from the MN. |

Table: LED "S/E" - Interface state (interface in POWERLINK mode)

Blink times

9.28.2.5.1.2 System stop error codes

A system stop error can occur due to incorrect configuration or defective hardware.

The error code is indicated by LED "S/E" blinking red. The blinking signal of the error code consists of 4 switch-on phases with short (150 ms) or long (600 ms) duration. The error code is repeated every 2 seconds.

| Error | Error description |
|----------------|---|
| RAM error | The device is defective and must be replaced. |
| Hardware error | The device or a system component is defective and must be replaced. |

9.28.2.5.2 Slot X2

| Figure | LED | Color | Status | Description |
|---|--------|-------|--------|--|
|  | 1 - 14 | Green | | Input state of the corresponding digital input |

Table 587: LED status indicators on the integrated X2 I/O slot

9.28.2.5.3 Slot X3

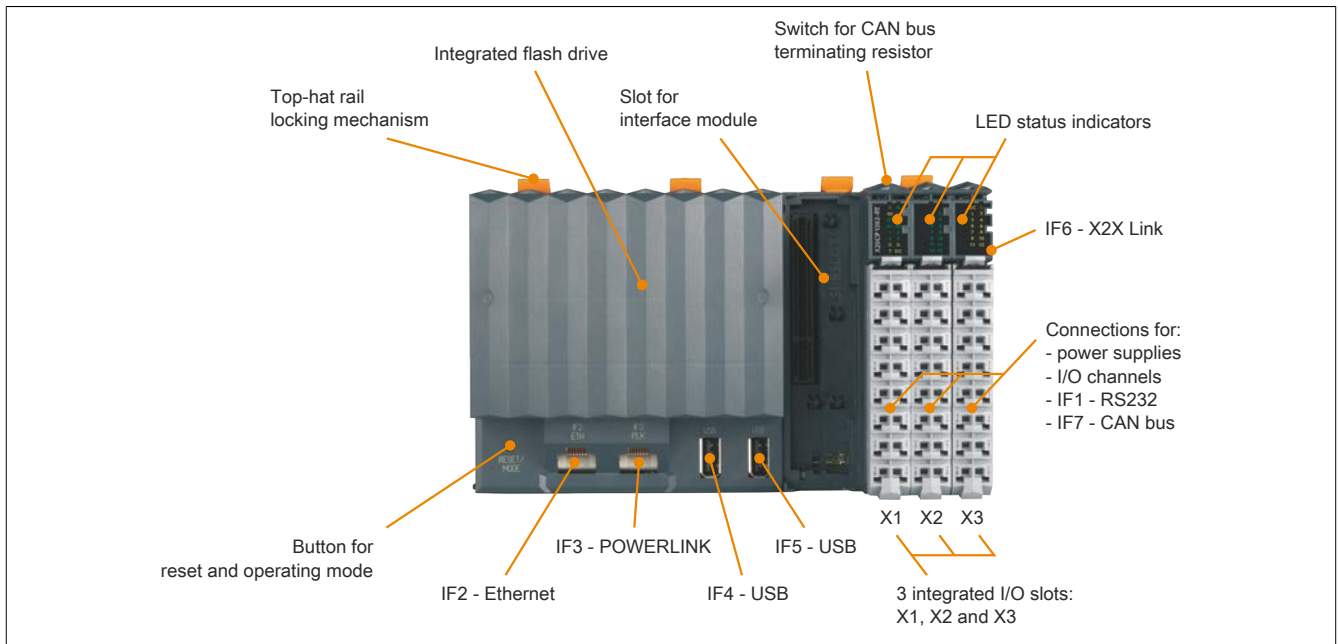

| Figure | LED | Color | Status | Description |
|---|--------|--------|--------------|---|
|  | DC | Yellow | On | I/O power supply OK |
| | E | Red | Off | Everything OK |
| | | | Double flash | No power to module |
| | 1 - 4 | Yellow | | Output status of the corresponding digital output |
| | 5 - 8 | Yellow | | Input or output status of the corresponding digital input or output |
| | 9 - 12 | Yellow | | Output status of the corresponding high-speed digital output |

Table 588: LED status indicators on the integrated X3 I/O slot

9.28.2.6 Operating and connection elements

9.28.2.6.1 Button for reset and operating mode

9.28.2.6.1.1 Reset

The button must be pressed for less than 2 seconds to trigger a reset. This triggers a hardware reset on the CPU, which means that:

- All application programs are stopped.
- All outputs are set to zero.

The controller then boots into service mode by default. The startup mode that follows after pressing the reset button can be set in Automation Studio.

- Service mode (default)
- Warm restart
- Cold restart
- Diagnostic mode

9.28.2.6.1.2 Operating mode

3 operating modes can be configured using different button sequences:

| Operating mode | Button sequence | Description |
|---------------------------|---|---|
| BOOT ¹⁾ | Boot mode is enabled by the following button sequence: <ul style="list-style-type: none"> • Press the button for less than 2 seconds. As soon as the "R" LED on the X1 I/O slot is lit RED, the button can be released. • Then press the button within 2 seconds for longer than 2 seconds. As soon as the "R" LED is no longer lit, the button can be released. | The default Automation Runtime system is started and the runtime system can be installed via the online interface (Automation Studio). User flash memory is deleted only after the download begins. |
| SERVICE/RUN ¹⁾ | Press the button for less than 2 seconds. As soon as the "R" LED on the X1 I/O slot is lit RED , the button can be released. | Mode SERVICE/RUN: Triggering and startup behavior correspond to triggering a hardware reset (see "Reset" on page 3392). |
| DIAGNOSE ¹⁾ | Press the button for more than 2 seconds. The "R" LED on the X1 I/O slot lights up RED and then goes out. As soon as the "R" LED is no longer lit, the button can be released. | Boots the CPU in diagnostic mode. Program sections in User RAM and User FlashPROM are not initialized. After diagnostic mode, the CPU always boots with a cold restart. |

1) The operating states are described in Automation Help under "Real-time operating system - Method of operation - Operating states".

9.28.2.6.2 Flash drive

This application memory is implemented as an integrated flash drive.

9.28.2.6.3 Project installation

Project installation is described in Automation Help under "Project management / Project installation".

9.28.2.6.4 RS232 interface (IF1)

The non-electrically isolated RS232 interface is primarily intended to serve as an online interface for communication with the programming device. It is located on the X1 I/O slot.

9.28.2.6.5 Ethernet interface (IF2)

The IF2 interface is designed for 10BASE-T / 100BASE-TX transmission.

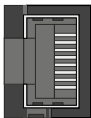

The INA2000 station number can be set using the Automation Studio software.

For information about wiring X20 modules with an Ethernet interface, see ["Cabling guidelines for X20 modules with an Ethernet cable" on page 58](#).

Information:

The Ethernet interface (IF2) is not suitable for POWERLINK (see ["POWERLINK interface \(IF3\)" on page 3394](#)).

Pinout

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | TXD | Transmit data |
| | 2 | TXD\ | Transmit data\ |
| | 3 | RXD | Receive data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | RXD\ | Receive data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.28.2.6.6 POWERLINK interface (IF3)

The CPUs are equipped with a POWERLINK V2 interface.

POWERLINK

By default, the POWERLINK interface is operated as a managing node (MN). In the managing node, the node number is set to a fixed value of 240.

If the POWERLINK node is operated as a controlled node (CN), a node number from 1 to 239 can be set in the POWERLINK configuration in Automation Studio.

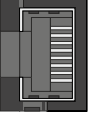

Ethernet mode

In this mode, the interface is operated as an Ethernet interface. The INA2000 station number is set using the B&R Automation Studio software.

Pinout

For information about wiring X20 modules with an Ethernet interface, see ["Cabling guidelines for X20 modules with an Ethernet cable"](#) on page 58.

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.28.2.6.7 USB interfaces (IF4 and IF5)

IF4 and IF5 are non-galvanically isolated USB interfaces. The abbreviation USB stands for "Universal Serial Bus". Both USB interfaces support the USB 1.1 and 2.0 standards.

Information:

USB peripheral devices can be connected to the USB interfaces. Due to the variety of USB devices available on the market, B&R cannot guarantee their functionality. The functionality of USB devices available from B&R is guaranteed.

Information:

- The USB interfaces cannot be used as online communication interfaces.
- Only devices isolated from GND are permitted to be connected to the USB interfaces.
- Current-carrying capacity is listed in the technical data.

9.28.2.6.8 CAN bus interface (IF7)

The compact CPUs are equipped with a non-electrically isolated CAN bus interface. It is located on the X1 I/O slot.

9.28.2.6.8.1 Pinout

9.28.2.6.8.2 Terminating resistor

Figure 282: Switch positions for the CAN bus terminating resistor

A terminating resistor is already installed on the X1 I/O slot. It can be turned on and off with a switch on top of the housing. An active terminating resistor is indicated by the "T" LED.

9.28.2.6.9 Slot for interface modules

These CPUs are equipped with one slot for interface modules.

Various bus and network systems can easily be integrated into the X20 system by selecting the corresponding interface module.

9.28.2.6.10 Data and real-time clock retention

The CPUs do not use a battery. This makes them completely maintenance-free. The following measures make operation without a backup battery possible.

| Data and real-time clock retention | Backup type | Note |
|------------------------------------|---------------------|---|
| Remanent variables | FRAM | This FRAM stores its contents ferroelectrically. Unlike normal SRAM, this does not require a battery. |
| Real-time clock | Gold foil capacitor | The real-time clock is backed up for approx. 1000 hours @ 25°C by a gold foil capacitor. The gold foil capacitor is completely charged after 3 continuous hours of operation. |

9.28.2.7 CPU supply

A power supply is integrated in these compact CPUs. It has a feed for the CPU, X2X Link and the internal I/O power supply. The supply for the CPU and X2X Link is electrically isolated.

The connections are located on the X3 I/O slot.

Power supply concept of Compact CPUs

To ensure proper operation of compact CPUs, the following items must be taken into consideration:

| The supply concept | Description |
|-------------------------|--|
| CPU and I/O GND | The GND contact is provided 5 times on the terminal blocks of the integrated I/O slots. All GND contacts are connected to one another. The GND contacts of the CPU and I/O power supply therefore use the same voltage. |
| Plug-in X20 I/O modules | Supply of X20 I/O modules that can be connected to the compact CPU: <ul style="list-style-type: none"> X2X Link: Supplied by the CPU supply I/O channels: Supplied by the I/O power supply |
| Integrated X1 I/O slot | All digital and analog signals as well as the RS232 and CAN bus interface are supplied by the CPU supply. Their operation is therefore guaranteed even if there is no I/O power supply. |
| Integrated X2 I/O slot | <ul style="list-style-type: none"> All digital signals are supplied by the CPU supply. Their operation is therefore guaranteed even if there is no I/O power supply. The encoder supply is supplied by the I/O power supply. If the encoder is not to be connected to the E-stop chain, then it must be connected to an external power supply or it will be supplied by the CPU supply. |
| Integrated X3 I/O slot | <ul style="list-style-type: none"> All 12 digital signals are supplied by the I/O power supply. The status messages for each channel also work without an I/O power supply. This guarantees that status messages will continue to be transferred during an E-stop. The status of the I/O power supply is indicated by a separate status message. <p>Caution!</p> <p>Channels 5 to 8 are designed as mixed channels. If one of these channels is being used, it is absolutely essential to ensure that there is no external voltage present on the I/O channel when the I/O power supply is cut off. Otherwise, power will be regenerated back to the plus terminal of the I/O power supply via the I/O channel. This will result in defective components.</p> <p>The following solutions are available for preventing power regeneration from occurring:</p> <ul style="list-style-type: none"> The I/O power supply of the CPU is not permitted to be switched off, which allows the reference potential to be maintained. If the I/O power supply is switched off anyway (e.g. as part of the E-stop chain), then the sensor/actuator supplies must also be switched off. This prevents potential power regeneration and protects components from being destroyed. |

Pinout

Connection example

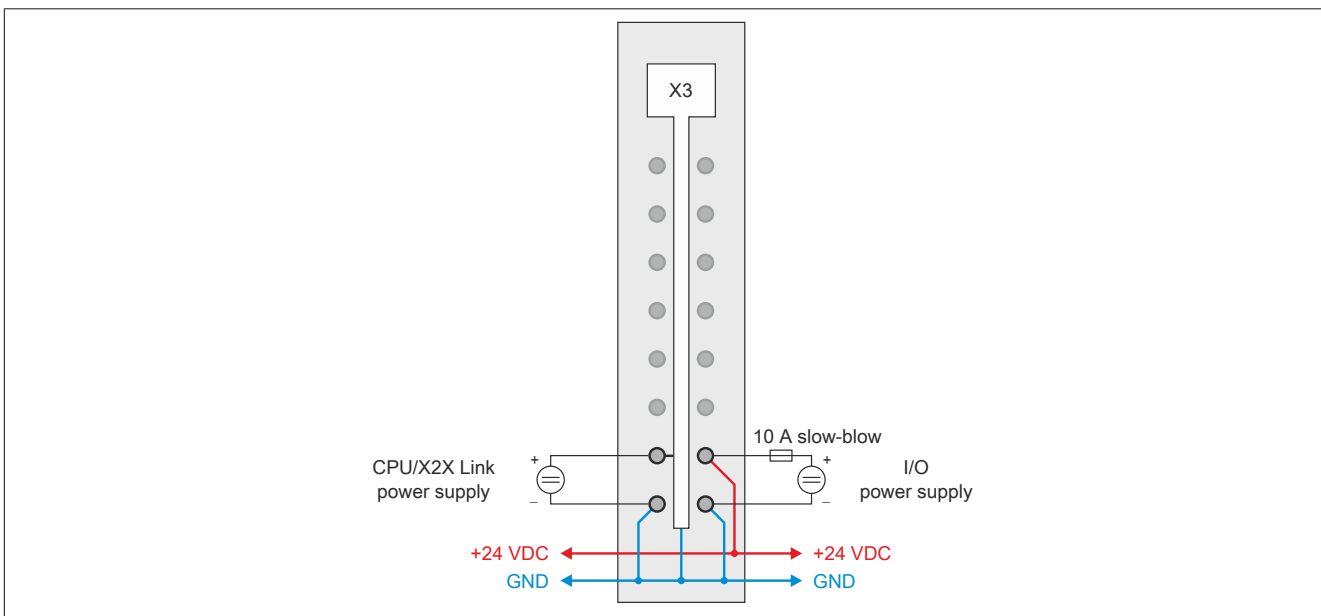

Figure 284: CPU supply - Connection example

9.28.2.8 Overtemperature cutoff

To prevent damage, a shutdown/reset is triggered on the CPU when the processor reaches 95°C.

The following errors are entered in the logbook in the event of shutdown:

| Error number | Short error text |
|--------------|--|
| 9204 | PLC restart triggered by the PLC CPU's temperature monitoring. |
| 9210 | Warning: Halt/Service after watchdog or manual reset. |

9.28.2.9 Local I/O channels

Compact CPUs are equipped with 3 integrated I/O slots. These devices have 30 digital inputs/outputs and 2 analog inputs.

Information about the functions of the high-speed digital inputs and outputs can be found in the section "[Functions of the high-speed digital inputs/outputs](#)" on page 3405.

The following table provides an overview of the connections to the I/O channels and their properties.

Digital inputs/outputs

| Connection | Terminal connection | Channel | Description |
|------------|---------------------|-------------|---|
| X1 | 14 | DI 1 | 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter |
| | 24 | DI 2 | 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter |
| | 15 | DI 3 | 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter |
| | 25 | DI 4 | 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter |
| X2 | 11 | DI 1 | 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter |
| | 21 | DI 2 | 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter |
| | ... | ... | ... |
| | 25 | DI 10 | 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter |
| | 16 | DI 11 | 24 VDC, sink, $\leq 2 \mu\text{s}$, configurable software filter |
| | 26 | DI 12 | 24 VDC, sink, $\leq 2 \mu\text{s}$, configurable software filter |
| | 17 | DI 13 | 24 VDC, sink, $\leq 2 \mu\text{s}$, configurable software filter |
| | 27 | DI 14 | 24 VDC, sink, $\leq 2 \mu\text{s}$, configurable software filter |
| X3 | 11 | DO 1 | 24 VDC, 0.5 A, source, $< 300 \mu\text{s}$ |

| | 12 | DO 3 | 24 VDC, 0.5 A, source, $< 300 \mu\text{s}$ |
| | 22 | DO 4 | 24 VDC, 0.5 A, source, $< 300 \mu\text{s}$ |
| | 13 | DI 5 / DO 5 | DI: 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter DO: 24 VDC, 0.5 A, source, $< 300 \mu\text{s}$ |
| | 23 | DI 6 / DO 6 | DI: 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter DO: 24 VDC, 0.5 A, source, $< 300 \mu\text{s}$ |
| | 14 | DI 7 / DO 7 | DI: 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter DO: 24 VDC, 0.5 A, source, $< 300 \mu\text{s}$ |
| | 24 | DI 8 / DO 8 | DI: 24 VDC, sink, $\leq 200 \mu\text{s}$, configurable software filter DO: 24 VDC, 0.5 A, source, $< 300 \mu\text{s}$ |
| | 15 | DO 9 | 24 VDC, 0.2 A, push-pull, $< 3 \mu\text{s}$ |
| | 25 | DO 10 | 24 VDC, 0.2 A, push-pull, $< 3 \mu\text{s}$ |
| | 16 | DO 11 | 24 VDC, 0.2 A, push-pull, $< 3 \mu\text{s}$ |
| | 26 | DO 12 | 24 VDC, 0.2 A, push-pull, $< 3 \mu\text{s}$ |

Analog inputs

| Connection | Terminal connection | Channel | Description |
|------------|---------------------|---------|---|
| X1 | 11, 12, 13 | AI 1 | $\pm 10 \text{ V} / 0$ to 20 mA or 4 to 20 mA, 12-bit, 1 ms |
| | 21, 22, 23 | AI 2 | $\pm 10 \text{ V} / 0$ to 20 mA or 4 to 20 mA, 12-bit, 1 ms |

Analog input 1 can also be used for PT1000 resistance temperature measurement.

| Connection | Terminal connection | Channel | Description |
|------------|---------------------|---------|---|
| X1 | 11, 12, 13 | AI 1 | PT1000 resistance temperature measurement Measurement takes place using analog input A1. |

The following sections describe assigning I/O channels in a reACTION program:

| I/O channels | Assignment |
|----------------------|--|
| Digital I/O channels | Assignment of digital inputs/outputs (Page 3439) |
| Analog I/O channels | Assignment of analog inputs (Page 3439) |

9.28.2.10 Pinouts

Slot X1

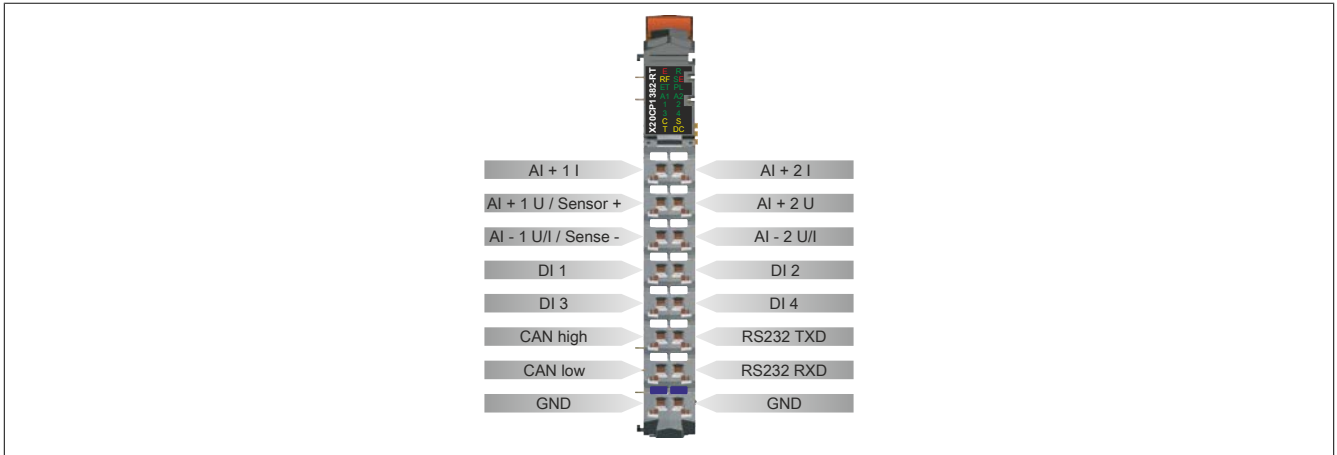

Figure 285: Pinout of the integrated X1 I/O slot

Slot X2

To prevent crosstalk, each signal line of the high-speed digital inputs should be shielded individually. The maximum cable length is 20 m.

Figure 286: Pinout of the integrated X2 I/O slot

Slot X3

To ensure proper operation of the digital mixed channels (DI 5 / DO 5 to DI 8 / DO 8), it is important to observe the notes in section ["Power supply concept of Compact CPUs"](#) on page 3397.

To prevent crosstalk, each signal line of the high-speed digital outputs should be shielded individually. The maximum cable length is 20 m.

9.28.2.12 Functions of the high-speed digital inputs/outputs

9.28.2.12.1 Functions of the high-speed digital inputs

Possible functions

The high-speed digital inputs DI 11 to DI 14 can be configured for the following functions: It is important to note that maximum 2 functions of the same type are possible with edge detection.

| Channel | Counter function | | | Edge detection ¹⁾ |
|---------|------------------|---|----------------------|---|
| DI 11 | Event counter 1 | A | A | D - Direction <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement <ul style="list-style-type: none"> • Edge counters • Edge times |
| DI 12 | | B | B | F - Frequency <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement <ul style="list-style-type: none"> • Edge counters • Edge times |
| DI 13 | Event counter 2 | A | R | R <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement <ul style="list-style-type: none"> • Edge counters • Edge times |
| DI 14 | | B | E - Reference enable | E - Reference enable <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement <ul style="list-style-type: none"> • Edge counters • Edge times |

Table 589: Possible functions of the high-speed digital inputs DI 11 to DI 14

1) Maximum 2 functions of the same type can be configured.

Please note

The following points must be taken into account to correctly configure the high-speed digital inputs:

- The counter functions are mutually exclusive. Only one type of counter function can be selected at a time. It is not possible to select 2 event counters (DI 11 and DI 13) at the same time together with an AB or DF counter (each on DI 13 and DI 14)!
- It is possible to select a counter function and edge detection at the same time.
- A position or counter latch is possible when configuring the high-speed inputs as a 2x event counter, ABR incremental encoder or DF function.

Examples of possible configurations

| Channel | Configuration 1 | Configuration 2 | Configuration 3 | Configuration 4 |
|---------|---|---|----------------------|----------------------|
| DI 11 | Event counter 1 | <ul style="list-style-type: none"> • Edge counters • Edge times | A | D |
| DI 12 | <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement | <ul style="list-style-type: none"> • Edge counters • Edge times | B | F |
| DI 13 | Event counter 2 | A | R | R |
| DI 14 | <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement | B | E - Reference enable | E - Reference enable |

| Channel | Configuration 5 | Configuration 6 | Configuration 7 | Configuration 8 |
|---------|---|---|---|---|
| DI 11 | Event counter 1 | A | <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement | D - Direction |
| DI 12 | <ul style="list-style-type: none"> • Edge counters • Edge times | B | <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement | F - Frequency |
| DI 13 | Event counter 2 | <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement | <ul style="list-style-type: none"> • Edge counters • Edge times | <ul style="list-style-type: none"> • Edge counters • Edge times |
| DI 14 | <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement | <ul style="list-style-type: none"> • Edge counters • Edge times | <ul style="list-style-type: none"> • Edge counters • Edge times | <ul style="list-style-type: none"> • Period measurement • Gate measurement • Differential time measurement |

9.28.2.12.2 Functions of the high-speed digital outputs

Possible functions

The high-speed digital outputs DO 9 to DO 12 can be configured for the following functions:

| Channel | Function | |
|---------|------------------------------|---------------|
| DO 9 | PWM - Pulse width modulation | D - Direction |
| DO 10 | PWM - Pulse width modulation | F - Frequency |
| DO 11 | PWM - Pulse width modulation | D - Direction |
| DO 12 | PWM - Pulse width modulation | F - Frequency |

Table 590: Possible functions of the high-speed digital inputs DO 9 to DO 12

Examples of possible configurations

| Channel | Configuration 1 | Configuration 2 | Configuration 3 | Configuration 4 |
|---------|------------------------------|------------------------------|------------------------------|-----------------|
| DO 9 | PWM - Pulse width modulation | D - Direction | PWM - Pulse width modulation | D - Direction |
| DO 10 | PWM - Pulse width modulation | F - Frequency | PWM - Pulse width modulation | F - Frequency |
| DO 11 | D - Direction | PWM - Pulse width modulation | PWM - Pulse width modulation | D - Direction |
| DO 12 | F - Frequency | PWM - Pulse width modulation | PWM - Pulse width modulation | F - Frequency |

9.28.2.14 Switching frequency derating for high-speed digital outputs

The high-speed digital outputs can be switched with a frequency of max. 200 kHz. Derating may be necessary depending on the mounting orientation and operating temperature.

Switching frequency derating for horizontal mounting orientations

Figure 301: Switching frequency derating for high-speed digital outputs with horizontal mounting orientations

Switching frequency derating for vertical mounting orientations

Figure 302: Switching frequency derating for high-speed digital outputs with vertical mounting orientations

9.28.2.15 Switching inductive loads

**Information:**

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

9.28.2.16 Register description

9.28.2.16.1 System requirements

The following minimum versions are recommended to generally be able to use all functions:

- Automation Studio 4.1.4.402
- Automation Runtime M4.10 for X20cCP1382-RT
- Automation Runtime D4.10 for all other variants

9.28.2.16.2 General data points

This CPU is equipped with general data points. These are not CPU-specific; instead, they contain general information such as system time and heat sink temperature.

General data points are described in section "[General CPU data points](#)" on page 3792.

9.28.2.16.3 Register overview of the I/O data points on the integrated X1 I/O slot

| Register | Name | Data type | Read | | Write | |
|---------------------------|--------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| X1 - Configuration | | | | | | |
| 2048 | X1CfO_DI_Filter | USINT | | | | • |
| 2128 | X1CfO_AI_Mode | USINT | | | | • |

| 0 | Digital inputs | USINT | • | | | |
| | DigitalInput01 | Bit 0 | | | | |
| | DigitalInput02 | Bit 1 | | | | |
| | DigitalInput03 | Bit 2 | | | | |
| | DigitalInput04 | Bit 3 | | | | |
| 64 | AnalogInput01 | INT | • | | | |
| | | UINT | • | | | |
| 66 | AnalogInput02 | INT | • | | | |
| 80 | StatusInput01 | USINT | • | | | |

9.28.2.16.3.1 Digital inputs**Unfiltered**

The input status is recorded in a 100 µs cycle.

Filtered

The filtered status is transferred in a 100 µs cycle.

Filtering takes place asynchronously in an interval of 100 µs.

Digital input filter

Name:

X1CfO_DI_Filter

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs.

| Data type | Value | Filter |
|-----------|-------|---|
| USINT | 0 | No SW filter |
| | 1 | 0.1 ms |
| | ... | ... |
| | 250 | 25 ms - Higher values are limited to this value |

Input state of digital inputs 1 to 4

Name:

DigitalInput01 to DigitalInput04

This register indicates the input state of digital inputs 1 to 4.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------|--------|---------------------------------|
| 0 | DigitalInput01 | 0 or 1 | Input status of digital input 1 |
| ... | | ... | |
| 3 | DigitalInput04 | 0 or 1 | Input status of digital input 4 |

9.28.2.16.3.2 Analog inputs

Analog input values are recorded in a fixed interval. The time required for conversion/updating depends on the number of analog inputs and on the input signal:

| Input signal | Time required for conversion/updating |
|--|---------------------------------------|
| 1 current/voltage input | 100 µs |
| 1 temperature/resistance input | 200 µs |
| 2 current/voltage inputs | 200 µs |
| 1 current/voltage input and 1 temperature/resistance input | 400 µs |

Input values of analog inputs

Name:

AnalogInput01

The analog input value is mapped in this register depending on the configured operating mode.

| Data type | Value | Input signal |
|-----------|-----------------|---|
| INT | -32768 to 32767 | Voltage signal -10 to 10 VDC |
| | 0 to 32767 | Current signal 0 to 20 mA (with 0 to 20 mA configuration) |
| | -8192 to 32767 | Current signal 0 to 20 mA (with 4 to 20 mA configuration) |
| | -2000 to 8500 | PT1000 signal -200.0 to 850.0°C |
| UINT | 0 to 40000 | Resistance signal 0 to 4000.0 Ω |

Name:

AnalogInput02

The analog input value is mapped in this register depending on the configured operating mode.

| Data type | Value | Input signal |
|-----------|-----------------|---|
| INT | -32768 to 32767 | Voltage signal -10 to 10 VDC |
| | 0 to 32767 | Current signal 0 to 20 mA (with 0 to 20 mA configuration) |
| | -8192 to 32767 | Current signal 0 to 20 mA (with 4 to 20 mA configuration) |

Status of the inputs

Name:

StatusInput01

This register holds the status of the analog inputs. A change in the monitoring status generates an error message. The following states are monitored depending on the settings:

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-------------------------|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Below lower limit value |
| | | 10 | Above upper limit value |
| | | 11 | Open circuit |
| 2 - 3 | Channel 2 | 00 | No error |
| | | 01 | Below lower limit value |
| | | 10 | Above upper limit value |
| | | 11 | Open circuit |
| 4 - 7 | Reserved | 0 | |

Limiting the analog value

In addition to the status information, the analog value is set to the limit values listed below by default when an error occurs (see "Limit values" on page 3419). The analog value is limited to the new values if the limit values were changed.

Input filter

The analog inputs are equipped with a configurable input filter.

Input ramp limiting

Input ramp limiting can only be performed in conjunction with filtering. Input ramp limiting is performed before filtering.

The difference of the input value change is checked for exceeding the specified limit. In the event of overshoot, the tracked input value is equal to the old value \pm the limit value.

Configurable limit values:

| Value | Limit value |
|-------|---|
| 0 | The input value is used without limitation. |
| 1 | 0x3FFF = 16383 |
| 2 | 0x1FFF = 8191 |
| 3 | 0x0FFF = 4095 |
| 4 | 0x07FF = 2047 |
| 5 | 0x03FF = 1023 |
| 6 | 0x01FF = 511 |
| 7 | 0x00FF = 255 |

Input ramp limiting is well suited for suppressing disturbances (spikes). The following examples show the functionality of input ramp limiting based on an input step and a disturbance.

Example 1

The input value jumps from 8000 to 17000. The diagram shows the tracked input value with the following settings:

Input ramp limiting = 4 = 0x07FF = 2047

Filter level = 2

Figure 303: Tracked input value for input step

Example 2

A disturbance interferes with the input value. The diagram shows the tracked input value with the following settings:

Input ramp limiting = 4 = 0x07FF = 2047

Filter level = 2

Figure 304: Tracked input value for disturbance

Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several bus cycles.

Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$\text{Value}_{\text{New}} = \text{Value}_{\text{Old}} - \frac{\text{Value}_{\text{Old}}}{\text{Filter level}} + \frac{\text{Input value}}{\text{Filter level}}$$

Adjustable filter levels:

| Value | Filter level |
|-------|---------------------|
| 0 | Filter switched off |
| 1 | Filter level 2 |
| 2 | Filter level 4 |
| 3 | Filter level 8 |
| 4 | Filter level 16 |
| 5 | Filter level 32 |
| 6 | Filter level 64 |
| 7 | Filter level 128 |

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8000 to 16000. The diagram shows the calculated value with the following settings:

Input ramp limiting = 0

Filter level = 2 or 4

Figure 305: Calculated value during input step

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limiting = 0

Filter level = 2 or 4

Figure 306: Calculated value during disturbance

Configuring the input filter

Name:

X1CfO_AI1_Filter

X1CfO_AI2_Filter

This register is used to define the filter level and input ramp limitation of the input filter.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------------|-------|--|
| 0 - 2 | Defines the filter level | 000 | Filter disabled (bus controller default setting) |
| | | 001 | Filter level 2 |
| | | 010 | Filter level 4 |
| | | 011 | Filter level 8 |
| | | 100 | Filter level 16 |
| | | 101 | Filter level 32 |
| | | 110 | Filter level 64 |
| | | 111 | Filter level 128 |
| 3 | Reserved | 0 | |
| 4 - 6 | Defines input ramp limiting | 000 | The input value is applied without limitation (bus controller default setting) |
| | | 001 | Limit value = 0x3FFF (16383) |
| | | 010 | Limit value = 0x1FFF (8191) |
| | | 011 | Limit value = 0x0FFF (4095) |
| | | 100 | Limit value = 0x07FF (2047) |
| | | 101 | Limit value = 0x03FF (1023) |
| | | 110 | Limit value = 0x01FF (511) |
| 111 | Limit value = 0x00FF (255) | | |
| 7 | Reserved | 0 | |

Channel type

Name:

X1CfO_AI_Mode

This register defines the type and range of signal measurement.

Each channel is capable of handling current, voltage or resistance signals. This differentiation is made using different terminal connections and an integrated switch. The switch is automatically activated depending on the specified configuration. The following input signals can be set:

| Input signal | On channel |
|--------------------------------|------------|
| ±10 V voltage signal (default) | 1 and 2 |
| 0 to 20 mA current signal | 1 and 2 |
| 4 to 20 mA current signal | 1 and 2 |
| PT1000 measurement | 1 |
| Resistance measurement | 1 |

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------|-------|---------------------------|
| 0 - 2 | Analog input - Channel 1 | 000 | Channel switched off |
| | | 001 | ±10 V voltage signal |
| | | 010 | 0 to 20 mA current signal |
| | | 011 | 4 to 20 mA current signal |
| | | 100 | PT1000 measurement |
| | | 101 | Resistance measurement |
| 3 | Reserved | 0 | |
| 4 - 5 | Analog input - Channel 2 | 00 | Channel switched off |
| | | 01 | ±10 V voltage signal |
| | | 10 | 0 to 20 mA current signal |
| | | 11 | 4 to 20 mA current signal |
| 6 - 7 | Reserved | 0 | |

Limit values

The input signal is monitored at the upper and lower limit values. By default the following limits are set for each mode:

| Limit value (default) | Voltage signal ± 10 V | | Current signal 0 to 20 mA | | Current signal 4 to 20 mA | |
|---------------------------|---------------------------|-----------------|---------------------------|-----------------|---------------------------|-----------------|
| Upper maximum limit value | 10 V | 32767 (0x7FFF) | 20 mA | 32767 (0x7FFF) | 20 mA | 32767 (0x7FFF) |
| Lower minimum limit value | -10 V | -32767 (0x8001) | 0 mA | 0 ¹⁾ | 4 mA | 0 ²⁾ |

Table 591: Limit values for voltage and current signals

- 1) The analog value is limited down to 0.
- 2) Due to the default limit value, the analog value is limited to a minimum of 0 at currents <4 mA.

| Limit value (default) | Temperature measurement | | Resistance measurement | |
|---------------------------|-------------------------|----------------|------------------------|----------------|
| Upper maximum limit value | 800.0°C | 8000 (0x1F40) | 4000.0 Ω | 32767 (0x7FFF) |
| Lower minimum limit value | -200.0°C | -2000 (0xF830) | 0 Ω | 0 |

Table 592: Limit values for temperature and resistance measurement

Other limit values can be defined if necessary. These are activated automatically by writing the limit value register (see "[Lower limit value](#)" on page 3419 and "[Upper limit value](#)" on page 3419). From this point on, the analog values will be monitored and limited according to the new limits. The results of monitoring are displayed in the status register (see "[Status of the inputs](#)" on page 3414).

Application example of setting limit values

A negative limit value must be configured in order to measure values <4 mA with a current signal of 4 to 20 mA: 0 mA corresponds to the value -8192 (0xE000).

Lower limit value

Name:

X1CfO_AI1_LowerLim

X1CfO_AI2_LowerLim

These registers can be used to configure the lower limit value for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set (see "[Status of the inputs](#)" on page 3414).

| Data type | Value |
|-----------|-----------------|
| INT | -32768 to 32767 |
| UINT | 0 to 65535 |

Information:

When configured as 4 to 20 mA, this value can be set to -8192 (corresponds to 0 mA) in order to display values <4 mA.

Upper limit value

Name:

X1CfO_AI1_UpperLim

X1CfO_AI2_UpperLim

These registers can be used to configure the upper limit value for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set (see "[Status of the inputs](#)" on page 3414).

| Data type | Value |
|-----------|------------|
| INT | 0 to 32767 |
| UINT | 0 to 65535 |

9.28.2.16.4 Register overview of the I/O data points on the integrated X2 I/O slot

| Register | Name | Data type | Read | | Write | |
|---------------------------|------------------------------|-----------|--------|---------|--------|---------|

9.28.2.16.4.1 Digital inputs**Unfiltered**

The input status is recorded in a 100 µs cycle.

Filtered

The filtered status is transferred in a 100 µs cycle.

Filtering takes place asynchronously in an interval of 100 µs.

Digital input filter

Name:

X2CfO_DI_Filter

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs.

| Data type | Value | Filter |
|-----------|-------|---|
| USINT | 0 | No SW filter |
| | 1 | 0.1 ms |
| | ... | ... |
| | 250 | 25 ms - Higher values are limited to this value |

Input state of digital inputs 1 to 14

Name:

DigitalInput01 to DigitalInput14

These registers are used to indicate the input state of digital inputs 1 to 14.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure of register 4096:

| Bit | Name | Value | Information |
|-----|----------------|--------|---------------------------------|
| 0 | DigitalInput01 | 0 or 1 | Input status of digital input 1 |
| ... | ... | ... | ... |
| 7 | DigitalInput08 | 0 or 1 | Input status of digital input 8 |

Bit structure of register 4097:

| Bit | Name | Value | Information |
|-----|----------------|--------|----------------------------------|
| 0 | DigitalInput09 | 0 or 1 | Input status of digital input 9 |
| ... | ... | ... | ... |
| 5 | DigitalInput14 | 0 or 1 | Input status of digital input 14 |

9.28.2.16.4.2 Edge detection

Digital inputs 11 to 14 can be used for high-speed edge detection. This runs parallel to all other functions such as counters, etc. This function does not use the digital input filter.

The edge detection function measures edges with μs precision. 2 units are available. A master and a slave edge can be configured for each unit. At each master edge, the timestamp of the master edge and the differential time to the previous slave edge (if present) are logged. A "Master count" can always be utilized to determine how many edges have been detected since the last task class cycle. The timestamp is based on the system time of the CPU.

The combination of rising/falling edges of each channel can be used to configure the following functions for each unit:

| Function | Description |
|-----------------|---|
| Edge time | Measure an edge time |
| Period duration | Measure the master and differential time |
| Gate time | Measure the master and differential time |
| Time offset | Measure the master and differential time of edges on different channels |

Edge detection unit - Mode settings

The edge detection unit needs to be configured according to the desired function.

| Function | Description |
|--|---|
| Basic timestamp, master edge mode | The current system time is saved as the master time at the time of the edge. |
| Timestamp and/or differential time, master and slave edge mode | The slave edge starts the measurement and the system time is saved temporarily. When the master edge occurs, the current system time is saved as the master time and the difference between the master and slave edges is calculated. |

Name:

X2CfO_EdgeDetectUnit01Mode

X2CfO_EdgeDetectUnit02Mode

These registers are used to configure the mode of the basic function for either just the master edge or both master and slave edges.

| Data type | Value | Information |
|-----------|-------|---|
| USINT | 0x00 | Edge detection disabled on Unit0x: Time measurement not possible |
| | 0x80 | Edge detection enabled on Unit0x: Reaction only possible for master edge, no differential measurement possible |
| | 0xC0 | Edge detection enabled on Unit0x: Reaction possible for configured master and slave edges |

Edge detection unit - Selection of master edge

Name:

X2CfO_EdgeDetectUnit01Master

X2CfO_EdgeDetectUnit02Master

These registers are used to select the source of the master edge for the respective unit. Either the rising or falling edge of one of the 4 high-speed digital input channels can be selected. Only one edge can be selected for each unit.

| Data type | Value | Information |
|-----------|-------|--|
| USINT | 0 | Digital input channel 11: Rising edge |
| | 2 | Digital input channel 12: Rising edge |
| | 4 | Digital input channel 13: Rising edge |
| | 6 | Digital input channel 14: Rising edge |
| | 1 | Digital input channel 11: Falling edge |
| | 3 | Digital input channel 12: Falling edge |
| | 5 | Digital input channel 13: Falling edge |
| | 7 | Digital input channel 14: Falling edge |

Edge detection unit - Selection of slave edge

Name:

X2CfO_EdgeDetectUnit01Slave

X2CfO_EdgeDetectUnit02Slave

These registers are used to select the source of the slave edge for the respective unit. Either the rising or falling edge of one of the 4 high-speed digital input channels can be selected. Only one edge can be selected for each unit.

| Data type | Value | Information |
|-----------|-------|--|
| USINT | 0 | Digital input channel 11: Rising edge |
| | 2 | Digital input channel 12: Rising edge |
| | 4 | Digital input channel 13: Rising edge |
| | 6 | Digital input channel 14: Rising edge |
| | 1 | Digital input channel 11: Falling edge |
| | 3 | Digital input channel 12: Falling edge |
| | 5 | Digital input channel 13: Falling edge |
| | 7 | Digital input channel 14: Falling edge |

Edge detection unit - Master edge counter

Name:

EdgeDetect01Mastercount

EdgeDetect02Mastercount

These registers hold the counter values of the detected master edges. The counter value is used to detect new measurements.

| Data type | Value | Information |
|-----------|-----------------|--|
| INT | -32768 to 32767 | Running counter: Number of detected master edges |

Edge detection unit - Master edge timestamp

Name:

EdgeDetect01Mastertime

EdgeDetect02Mastertime

The exact CPU system time of the respective unit is saved to these registers when a master edge occurs. If multiple master edges occur within a single cycle (task class), then the time of the last edge is shown.

| Data type | Value | Information |
|-----------|---------------------------------|---|
| DINT | -2,147,483,648 to 2,147,483,647 | CPU system time of master edge [μ s] |

Edge detection unit - Time difference

Name:

EdgeDetect01Difference

EdgeDetect02Difference

The difference between the master edge and the slave edge of the respective unit is saved to these registers. If multiple measurement periods are completed within a single cycle (task class), then the time difference from the last period is shown.

| Data type | Value | Information |
|-----------|---------------------------------|---|
| DINT | -2,147,483,648 to 2,147,483,647 | Time difference between master edge and slave edge [μ s] |

9.28.2.16.4.3 Counter functions

High-speed digital inputs 11 to 14 can be used for counter functions. This function does not use the digital input filter. The following functions are available. Only one of these basic configurations can be enabled at a time:

- 2x event counter with latch function
- 2x AB incremental counter without latch function
- DF counter function
- ABR counter function

Configuring the counter function

The following counter functions can be configured:

| Counter function | Description |
|--|--|
| 2x event counter with latch function | Input 11 for event counter 1 and input 13 for event counter 2 can be used simultaneously as event counters. Both rising and falling edges are counted. The latch function of all 4 inputs can be used. |
| 2x AB incremental counter without latch function | Inputs 11 and 12 as AB counter 1 and inputs 13 and 14 as AB counter 2. Since no more high-speed inputs are available, the latch function is not available. |
| DF counter: Direction/Frequency with latch function | The D, F and R signals are linked to inputs 11, 12 and 13. Signal D defines the positive (Level = 0) or negative (Level = 1) counting direction. The latch function of all 4 inputs can be used. |
| ABR counter with latch function | The A, B and R signals are linked to inputs 11, 12 and 13. The latch function of all 4 inputs can be used. |

Name:

X2CfO_CounterMode

This register configures the counter function:

| Data type | Value | Information |
|-----------|-------|--|
| USINT | 0 | 2x event counter with latch function |
| | 1 | 2x AB incremental counter without latch function |
| | 2 | DF counter with latch function |
| | 3 | ABR counter with latch function |

Configuring the mode of the latch function

Name:

X2CfO_Latch01Mode

X2CfO_Latch02Mode

This register sets the mode of the latch function. The following latch functions can be configured:

| Latch function | Description |
|------------------------|--|
| Single shot latch mode | The latch function must be enabled/set. After a successful latch procedure the function must first be reset. Then it can be enabled again. |
| Continuous latch mode | The latch function only has to be enabled/set as long as latching is desired. |

A changed counter value on "LatchCount" indicates that the latch procedure has been performed (see "[Counter value of latch events](#)" on page 3426). The counter value is stored in the latch register (see "[Latched counter value](#)" on page 3426).

| Data type | Value | Information |
|-----------|-------|------------------------|
| USINT | 0 | Single shot latch mode |
| | 1 | Continuous latch mode |

Configuring the latch signals

Name:

X2CfO_Latch01Comparator

X2CfO_Latch02Comparator

This register defines the inputs and their level for triggering the latch procedure.

- This defines which inputs are linked to generate the latch event. All 4 digital input signals can be used for an "AND" connection.
- The "active voltage level" needed for the latch procedure can be defined to adjust for the physical signals. It is not possible to configure a high and low level at the same time.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Value | Information |
|-----|-------|--|
| 0 | 0 | Input 11 high level disabled |
| | 1 | Input 11 high level enabled for comparator |
| 1 | 0 | Input 12 high level disabled |
| | 1 | Input 12 high level enabled for comparator |
| 2 | 0 | Input 13 high level disabled |
| | 1 | Input 13 high level enabled for comparator |
| 3 | 0 | Input 14 high level disabled |
| | 1 | Input 14 high level enabled for comparator |
| 4 | 0 | Input 11 low level disabled |
| | 1 | Input 11 low level enabled for comparator |
| 5 | 0 | Input 12 low level disabled |
| | 1 | Input 12 low level enabled for comparator |
| 6 | 0 | Input 13 low level disabled |
| | 1 | Input 13 low level enabled for comparator |
| 7 | 0 | Input 14 low level disabled |
| | 1 | Input 14 low level enabled for comparator |

Clear counter value and enable/disable latch function

Name:

Counter01Reset

Counter02Reset

Latch01Enable

Latch02Enable

The respective bits in these registers clear the counter value or start the latch procedure.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------|-------|--------------------------|
| 0 | Counter0xReset | 0 | Do not reset the counter |
| | | 1 | Reset the counter |
| 1 | Latch0xEnable | 0 | Do not latch the counter |
| | | 1 | Latch the counter |
| 2 - 7 | Reserved | 0 | |

Counter value

Name:

Counter01Value

Counter02Value

The current counter values are saved in these registers.

| Data type | Value | Information |
|-----------|---------------------------------|-----------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Current counter value |

Latched counter value

Name:

Counter01Latch

Counter02Latch

As soon as the latch conditions have been met, the value of the respective counter is copied to these registers.

| Data type | Value | Information |
|-----------|---------------------------------|-----------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Latched counter value |

Counter value of latch events

Name:

Latch01Count

Latch02Count

These registers hold the counter values of the latch events. This allows detection of whether a new latched counter value has been saved.

| Data type | Value | Information |
|-----------|-------------|--|
| SINT | -128 to 127 | Running counter: Number of detected latch events |

Timestamp of last counter change

Name:

Counter01TimeChanged

Counter02TimeChanged

The CPU system time at the time of the last change to the counter value is saved in these registers.

| Data type | Value | Information |
|-----------|---------------------------------|---|
| DINT | -2,147,483,648 to 2,147,483,647 | The CPU system time at the time of the last change to the counter value |

Timestamp of last valid counter value

Name:

Counter01TimeValid

Counter02TimeValid

The CPU system time at the time of the last valid counter value is saved in these registers.

| Data type | Value | Information |
|-----------|---------------------------------|--|
| DINT | -2,147,483,648 to 2,147,483,647 | CPU system time of current counter value |

9.28.2.16.5 Register overview of the I/O data points on the integrated X3 I/O slot

| Register | Name | Data type | Read | | Write | |
|---------------------------|-----------------------|-----------|--------|---------|--------|---------|

9.28.2.16.5.1 Physical configuration of I/O channels

These registers are used to define the functionality of the channels. Depending on the desired configuration, the following assignments can be made with respect to the existing software and hardware:

- A physical configuration as input or output for mixed channels
- An explicit assignment as direct I/O channel: i.e. digital input or digital output
- An explicit assignment as PWM output
- An explicit assignment as D or F movement output
- An explicit assignment for reACTION Technology

Information:

For all input signals of slots X1 and X2, explicit assignment is not necessary, since the channels can be read simultaneously from the I/O map and reACTION Technology.

Physical configuration

Name:

X3CfO_PhylIOConfigCh01 to X3CfO_PhylIOConfigCh12

These registers are used to configure the functionality of the channels.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

Name:

X3CfO_PhylIOConfigCh01 to X3CfO_PhylIOConfigCh04

Channels 1 to 4 are digital outputs and can only be used as direct I/O channel or for reACTION Technology.

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------------|
| 0 - 5 | Reserved | 0 | |
| 6 | | 0 | Direct I/O operation of output |
| | | 1 | Operation via reACTION Technology |
| 7 | Reserved | 0 | |

Name:

X3CfO_PhylIOConfigCh05 to X3CfO_PhylIOConfigCh08

Channels 5 to 8 are digital mixed channels and can be configured as either input or output. They can be operated either as direct I/O channels or via reACTION Technology.

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------------|
| 0 - 1 | | 00 | Configured as digital output |
| | | 01 | Reserved |
| | | 10 | Reserved |
| | | 11 | Configured as digital input |
| 2 - 5 | Reserved | 0 | |
| 6 | | 0 | Direct I/O operation of output |
| | | 1 | Operation via reACTION Technology |
| 7 | Reserved | 0 | |

Name:

X3CfO_PhylIOConfigCh09 to X3CfO_PhylIOConfigCh12

Channels 9 to 12 are high-speed digital outputs and can be configured as direct I/O, PWM or movement channels or used for reACTION Technology.

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------------|
| 0 - 3 | Reserved | 0 | |
| 4 - 6 | | 000 | Direct I/O operation of output |
| | | 001 | Output operated as PWM |
| | | 010 | Reserved |
| | | 011 | Output operated as D/F movement |
| | | 100 | Operation via reACTION Technology |
| | | 101 | Reserved |
| | | 110 | Reserved |
| | | 111 | Reserved |
| 7 | Reserved | 0 | |

9.28.2.16.5.2 Monitoring of the I/O power supply voltage

Name:

StatusInput01

The state of the I/O supply voltage is indicated in this register.

| Data type | Values | Information |
|-----------|--------|--|
| USINT | 0 | I/O power supply voltage within permissible range |
| | 1 | I/O power supply voltage not connected or outside of the permissible range |

9.28.2.16.5.3 Digital inputs**Unfiltered**

The input status is recorded in a 100 µs cycle.

Filtered

The filtered status is transferred in a 100 µs cycle.

Filtering takes place asynchronously in an interval of 100 µs.

Digital input filter

Name:

X3CfO_DI_Filter

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs.

| Data type | Value | Filter |
|-----------|-------|---|
| USINT | 0 | No SW filter |
| | 1 | 0.1 ms |
| | ... | ... |
| | 250 | 25 ms - Higher values are limited to this value |

Input state of digital inputs 5 to 8

Name:

DigitalInput05 to DigitalInput08

This register indicates the input state of digital inputs 5 to 8.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------|--------|---------------------------------|
| 0 | DigitalInput05 | 0 or 1 | Input status of digital input 5 |
| ... | | ... | |
| 3 | DigitalInput08 | 0 or 1 | Input status of digital input 8 |

9.28.2.16.5.4 Digital outputs

The output status is processed in a 100 µs cycle.

Switching state of digital outputs 1 to 12

Name:

DigitalOutput01 to DigitalOutput12

These registers are used to store the switching state of digital outputs 1 to 12.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

Register 8208:

| Bit | Description | Value | Information |
|-----|-----------------|-------|------------------------|
| 0 | DigitalOutput01 | 0 | Digital output 1 reset |
| | | 1 | Digital output 1 set |
| ... | | ... | |
| 7 | DigitalOutput08 | 0 | Digital output 8 reset |
| | | 1 | Digital output 8 set |

Register 8209:

| Bit | Description | Value | Information |
|-----|-----------------|-------|-------------------------|
| 0 | DigitalOutput09 | 0 | Digital output 9 reset |
| | | 1 | Digital output 9 set |
| ... | | ... | |
| 3 | DigitalOutput12 | 0 | Digital output 12 reset |
| | | 1 | Digital output 12 set |

9.28.2.16.5.5 Monitoring status of the digital outputs

The error states of the outputs must be programmed in the application. The status information that is read is the actual voltage state on the channel (set or reset). The error state is therefore determined by a difference between the data points "DigitalOutputxx" and the corresponding "StatusDigitalOutputxx".

At least 3 system ticks are needed internally to read the output status. This is the reason for the delay after which the earliest possible comparison can be made after a change in the status of the output.

The digital input filter is not applied to this status information.

Status of digital outputs 1 to 12

Name:

StatusDigitalOutput01 to StatusDigitalOutput12

These registers are used to indicate the status of digital outputs 1 to 12.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

Register 8193:

| Bit | Description | Value | Information |
|-----|-----------------------|-------|---|
| 0 | StatusDigitalOutput01 | 0 | Channel 1: Digital output reset or short circuit |
| | | 1 | Channel 1: Digital output set or voltage feedback |
| ... | | ... | |
| 7 | StatusDigitalOutput08 | 0 | Channel 8: Digital output reset or short circuit |
| | | 1 | Channel 8: Digital output set or voltage feedback |

Register 8194:

| Bit | Description | Value | Information |
|-----|-----------------------|-------|--|
| 0 | StatusDigitalOutput09 | 0 | Channel 9: Digital output reset or short circuit |
| | | 1 | Channel 9: Digital output set or voltage feedback |
| ... | | ... | |
| 3 | StatusDigitalOutput12 | 0 | Channel 12: Digital output reset or short circuit |
| | | 1 | Channel 12: Digital output set or voltage feedback |

9.28.2.16.5.6 Pulse width modulation (PWM) function

Digital inputs 9 to 12 can be configured as PWM outputs. 2 data points are available per channel for controlling the PWM signal.

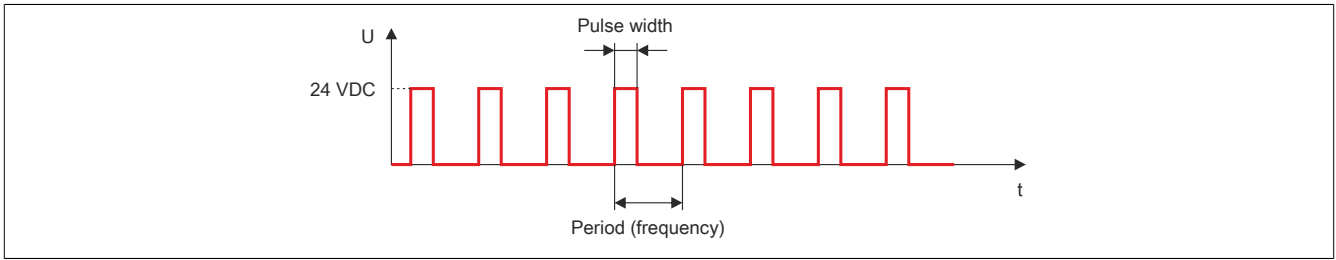

Figure 307: The PWM signal is controlled by setting the pulse width and period duration

Period duration of the PWM outputs

Name:

PWMPeriod09 to PWMPeriod12

These registers are used to define the duration of the period duration, i.e. the time base for the respective PWM output. This time represents the 100% value, which can be resolved to 0.1% through the duty cycle.

| Data type | Value | Information |
|-----------|------------|--|
| UINT | 5 to 65535 | Period duration, between 5 and 65535 μ s: Corresponds to a frequency of 200 kHz to \approx 15 Hz |

Duty cycle of the PWM outputs

Name:

PWMOutput09 to PWMOutput12

These registers output the duty cycle of the respective PWM output in a resolution of 0.1% of the period duration.

| Data type | Value | Information |
|-----------|-----------|---|
| INT | 0 to 1000 | Duty cycle of the output in 0 to 100.0% |

Example: Period duration T [μ s] with a duty cycle of 25% equals a duty time of t_1 [μ s].

Figure 308: Switch-on time depending on the period duration and duty cycle

9.28.2.16.5.7 DF movement generator function

Digital output channels 9 to 12 can be configured as 2 independently functioning movement generators (Direction/Frequency) for stepper motor control. The movement generators are assigned to the following channels:

| Movement generator | Channel | Function |
|--------------------|---------|--------------|
| 1 | DO 9 | D: Direction |
| | DO 10 | F: Frequency |
| 2 | DO 11 | D: Direction |
| | DO 12 | F: Frequency |

The frequency is output via the respective F channel, and the direction is output via the respective D channel. The switchover between directions (movement/counter) takes place via the sign of the speed setpoint.

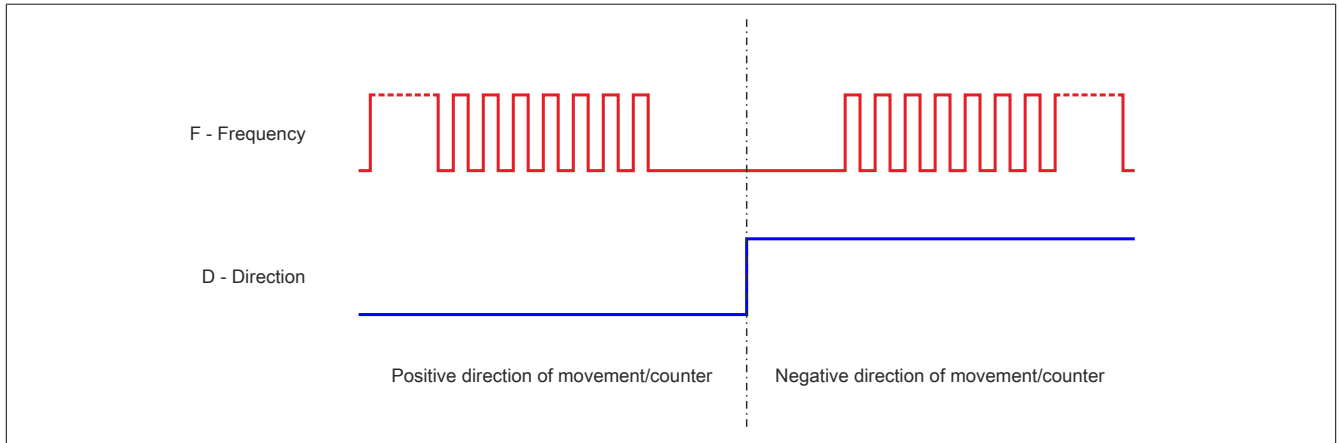

Figure 309: Frequency output via F channel, direction output via D channel

The respective output must be configured correctly in order to completely process the motion function (see ["Physical configuration" on page 3428](#)).

The data points described below are available for configuring and controlling the respective movements.

Configuring the movement mode

Name:

X3Cfo_Mov01Mode

X3Cfo_Mov02Mode

These registers are used to configure how the speed setpoint is interpreted. The difference between the two modes is whether edges or periods are output for each increment of the setpoint.

| Data type | Value | Information |
|-----------|-------|---|
| USINT | 0 | Edge mode: Each increment generates an edge on the output |
| | 1 | Pulse mode: Each increment generates a period on the output |

Edge mode

4 increments of the speed setpoint correspond to 2 periods on the output:

Figure 310: Interpretation of the speed setpoint with edge output for each increment

Pulse mode

2 increments of the speed setpoint correspond to 2 periods on the output:

Figure 311: Interpretation of the speed setpoint with period output for each increment

Configuring the maximum speed of the movement

The maximum speed or output frequency of the movement is configured in order to protect the digital output, the actuator/drive being controlled and/or the mechanical system.

Name:

X3Cfo_Mov01SpeedLimit

X3Cfo_Mov02SpeedLimit

These registers are used to configure the maximum speed / output frequency permitted in the system. It is important that the limit values for edge and pulse mode are different.

Edge mode

| Data type | Value | Information |
|-----------|--------------|-------------------------------|
| UDINT | 10 to 400000 | Speed [increments per second] |

Pulse mode

| Data type | Value | Information |
|-----------|-------------|-------------------------------|
| UDINT | 5 to 200000 | Speed [increments per second] |

Activates the movement

When a movement is active, the two channels are operated according to the preset values.

Name:

Mov01Enable

Mov02Enable

These registers are used to enable or disable the motion function.

Mov01Enable

| Data type | Value | Information |
|-----------|-------|---|
| USINT | 0 | Movement 1 disabled |
| | 2 | Movement 1 enabled: The speed setpoint is evaluated |

Mov02Enable

| Data type | Value | Information |
|-----------|-------|---|
| USINT | 0 | Movement 2 disabled |
| | 4 | Movement 2 enabled: The speed setpoint is evaluated |

Speed and direction control of the movement

The following parameters are important for speed and direction control of the movement:

| Characteristic value | Description |
|----------------------------------|---|
| Speed control | The predefined speed is specified as a percentage of the configured maximum speed. 0 to ± 32767 correspond to 0 to $\pm 100\%$ of the configured maximum speed |
| Direction control | The direction of movement is defined by the sign of the speed setpoint: 0 to +32767 correspond to 0 to the maximum speed in the positive direction of movement 0 to -32767 correspond to 0 to the maximum speed in the negative direction of movement |
| Resolution of the speed setpoint | The resolution of the speed setpoint is: $\text{Maximum speed} / 32767$ |
| Relationship: Speed / Frequency | The relationship between speed and output frequency is: $(\text{Speed setpoint} / \text{Maximum speed}) * 32767$ |

Table 593: Parameters for speed and direction control of the movement

Name:

Mov01Speed

Mov02Speed

These registers are used to set the speed of the movement.

| Data type | Value | Information |
|-----------|-------------|--|
| INT | 0 to 32767 | Speed setpoint 0 to 100%: Movement output F = 0 to maximum speed Positive direction of movement: Movement output D = 0 |
| | 0 to -32767 | Speed setpoint 0 to 100%: Movement output F = 0 to maximum speed Negative direction of movement: Movement output D = 1 |

Position feedback for movement

The position feedback is represented by a fixed point value [16.16]:

- HighWord = whole number increments
- LowWord = positions after the decimal of the increments

Name:

Mov01Position

Mov02Position

These registers show the current position of the movement.

| Data type | Value | Information |
|-----------|---------------------------------|--|
| DINT | -2,147,483,648 to 2,147,483,647 | Position value in fixed point format [16.16] |

9.28.2.16.6 reACTION Technology

All integrated I/O channels are reACTION-capable and can be operated by the reACTION program. These I/O channels are controlled with a response time up to 1 μ s. All of the commands that can be used for reACTION programs are provided as function blocks in special libraries (e.g. AsIORTI). Programming using the standard Function Block Diagram (FBD) editor in Automation Studio is compliant with IEC 61131-3.

When using the "reACTION" function, an individual reACTION program must be created. This makes it possible to manage individual machine tasks decentrally and with extremely short reaction times. Interaction registers are used to exchange information between the CPU and the reACTION program.

9.28.2.16.6.1 Register overview - reACTION Technology

| Register | Name | Data type | Read | | Write | |

9.28.2.16.6.2 reACTION - Configuration

The reACTION program is executed with its own time base. The desired cycle time must be defined. If the cycle time cannot be achieved, the reACTION program is executed with the smallest possible cycle time.

Configuring the cycle time

The following 2 registers are used to define the desired cycle time for the reACTION program. The "TimeValue" register contains the value, while the "Multiplier" register contains the associated units.

Name:

ReActionCycleTimeMultiplier

This register must be set to a fixed value of 1000, which sets the units to [μ s].

| Data type | Value |
|-----------|-------|
| DINT | 1000 |

Name:

ReActionCycleTimeValue

The cycle time of the reACTION program is set using this register.

| Data type | Value |
|-----------|----------------------|
| DINT | 1 to 1000 [μ s] |

Configuring the PAR data points

Name:

CfO_PARType01 to CfO_PARType04

PAR data points can be defined for the reACTION program. In order to enable them, the desired data type must be made known according to the configuration in Automation Studio.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|-----------------|-------|-------------|
| 0 - 3 | Type01 - PAR 1 | 0000 | Inactive |
| | Type02 - PAR 9 | 0001 | USINT, BOOL |

9.28.2.16.6.3 reACTION function blocks - General

The following table provides an overview of I/O channel assignments to reACTION function blocks.

Digital inputs/outputs

| Channel | Function block | | |
|-----------------|-----------------------|-------------|----------------------|
| | Mapping ¹⁾ | rtiDin | rtiDout, rtiDoutTime |
| X1: DI 1 | 0x00 | Channel 101 | |
| X1: DI 2 | 0x01 | Channel 102 | |
| X1: DI 3 | 0x02 | Channel 103 | |
| X1: DI 4 | 0x03 | Channel 104 | |
| X2: DI 1 | 0x08 | Channel 201 | |
| X2: DI 2 | 0x09 | Channel 202 | |
| X2: DI 3 | 0x0A | Channel 203 | |
| X2: DI 4 | 0x0B | Channel 204 | |
| X2: DI 5 | 0x0C | Channel 205 | |
| X2: DI 6 | 0x0D | Channel 206 | |
| X2: DI 7 | 0x0E | Channel 207 | |
| X2: DI 8 | 0x0F | Channel 208 | |
| X2: DI 9 | 0x10 | Channel 209 | |
| X2: DI 10 | 0x11 | Channel 210 | |
| X2: DI 11 | 0x12 | Channel 211 | |
| X2: DI 12 | 0x13 | Channel 212 | |
| X2: DI 13 | 0x14 | Channel 213 | |
| X2: DI 14 | 0x15 | Channel 214 | |
| X3: DO 1 | 0x00 | | Channel 301 |
| X3: DO 2 | 0x01 | | Channel 302 |
| X3: DO 3 | 0x02 | | Channel 303 |
| X3: DO 4 | 0x03 | | Channel 304 |
| X3: DI 5 / DO 5 | 0x04 | Channel 305 | Channel 305 |
| X3: DI 6 / DO 6 | 0x05 | Channel 306 | Channel 306 |
| X3: DI 7 / DO 7 | 0x06 | Channel 307 | Channel 307 |
| X3: DI 8 / DO 8 | 0x07 | Channel 308 | Channel 308 |
| X3: DO 9 | 0x08 | | Channel 309 |
| X3: DO 10 | 0x09 | | Channel 310 |
| X3: DO 11 | 0x0A | | Channel 311 |
| X3: DO 12 | 0x0B | | Channel 312 |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rtiABRPos) (see "reACTION function blocks - Configuration" on page 3440).

Analog inputs

| Channel | Function block | | |
|----------|-----------------------|-----------|---------|
| | Mapping ¹⁾ | rtiAin | rtiAout |
| X1: AI 1 | 0x00 | Channel 1 | |
| X1: AI 2 | 0x01 | Channel 2 | |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rtiABRPos) (see "reACTION function blocks - Configuration" on page 3440).

9.28.2.16.6.4 reACTION function blocks - Configuration

Some function blocks in library AsIoRti must be configured before they can be used.

| Function block | Information |
|----------------|--|
| rtiABRPos | The module offers the option of using function block rtiABRPos once in the reACTION program. To do so, the function block must be assigned 3 digital inputs that are no longer available for rtiDin. |
| rtiABCnt | The module offers the option of using function block rtiABCnt up to 3 times in the reACTION program. To do so, the function blocks must be assigned 2 digital inputs as an A or B track that are no longer available for rtiDin. In addition, an external event can be defined for each rtiABCnt function block. The input used for this is also no longer available for rtiDin. |

Table 594: List of function blocks requiring prior configuration

Function blocks rtiABRPos and rtiABCnt

Function blocks rtiABRPos and rtiABCnt can be used to process the position value of an ABR incremental encoder in a reACTION task. Several hardware channels of the module are used for this. The incoming signals are interpreted by the reACTION engine and converted into a location.

The update rate depends on both the reACTION engine and the hardware used. The reACTION engine is basically able to calculate positions with an update rate of up to 8 MHz. The input frequencies of the hardware inputs can be taken from the technical data of the respective module.

These function blocks can be used separately or in combination.

Using function block rtiABRPos

The following points are important to keep in mind when using function block rtiABRPos in a reACTION program:

- The function block can only be used once in a reACTION program.
- 3 digital inputs must be defined on the module for input signals A, B and R.
- In addition, a digital input of the module can be defined as an event input.

Example diagram of input signals:

Figure 312: Schematic diagram of input signals for rtiABRPos

Using function block rtiABCnt

The following points must be taken into account when using function block rtiABCnt in a reACTION program:

- The function block can be used up to 3 times in a reACTION program.
- 2 digital inputs must be defined on the module for input signals A and B.
- In addition, up to 3 digital inputs on the module can be defined as event inputs E1, E2 and E3.

Example diagram of input signals:

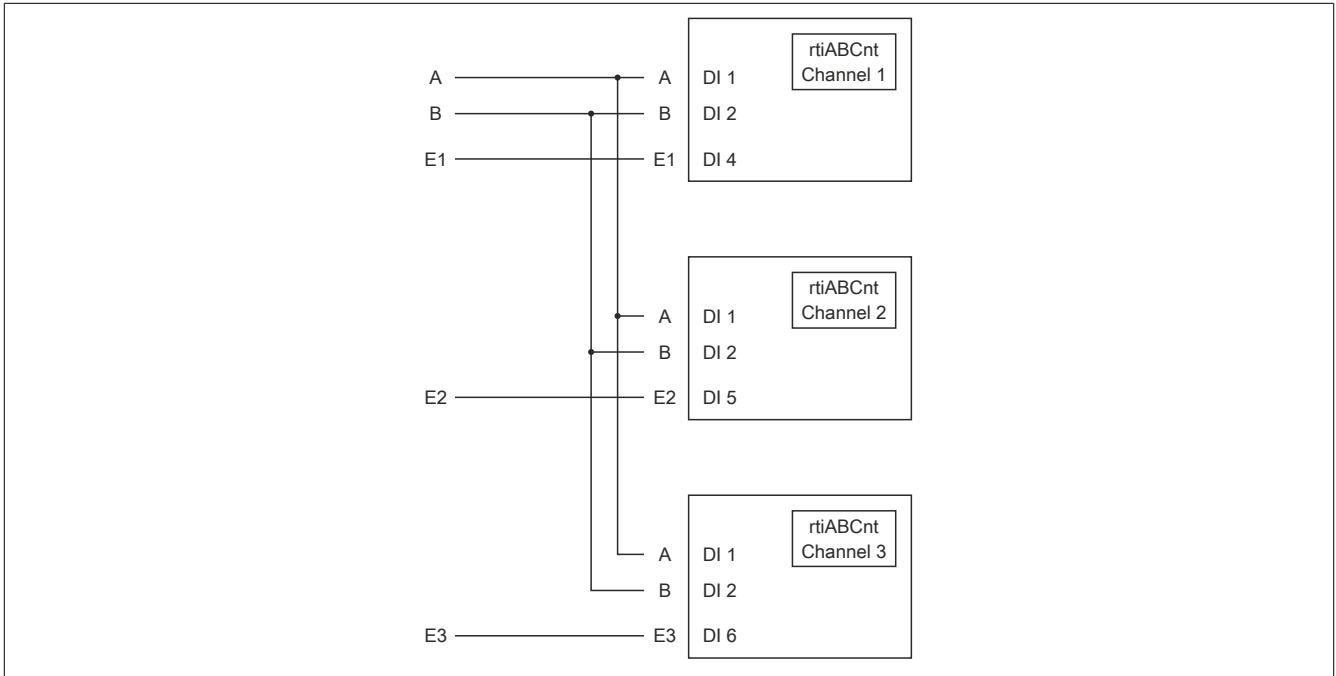

Figure 313: Schematic diagram of input signals for rtiABCnt

Using function blocks rtiABRPos and rtiABCnt in combination

The following points should be kept in mind when using function blocks rtiABRPos and rtiABCnt together in a reACTION program.

- Function block rtiABRPos can only be used once in a reACTION program.
- Function block rtiABCnt can be used up to 2 times in a reACTION program.
- 3 digital inputs must be defined for input signals A, B and R (rtiABRPos).
- The same digital inputs are used for input signals A and B (rtiABCnt).
- In addition, up to 3 event inputs E1, E2 and E3 can be defined (rtiABCnt).
- E1 is used for the event input (rtiABRPos).

Example diagram of input signals:

Figure 314: Diagram of input signals when using rtiABRPos and rtiABCnt at the same time

Registering the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_Config_ABR1

This register specifies the technical characteristics of the connected ABR incremental encoder.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|------------|---|
| 0 - 15 | Increments per revolution | 0 to 65535 | Reference pulse monitoring: If the reference pulse is different than defined here, this is indicated on the status output of function block rtiABRPos. |
| 16 | Inversion of the counting direction set by signals A and B | 0 | Positive counting direction |
| | | 1 | Negative counting direction |
| 17 - 31 | Reserved | 0 | |

Wiring the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_ChannelMapping1_ABR1

CfO_ChannelMapping2_ABR1

Before function blocks rtiABRPos/rtiABCnt can be processed by the reACTION engine, the hardware inputs to be used by the ABR incremental encoder must be defined on the module. The "ChannelMapping" registers specify which inputs are interpreted as the A, B, R, E1, E2 and E3 signals.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure of CfO_ChannelMapping1_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---------------------------------------|
| 0 - 7 | Input E1 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 8 - 15 | Input R | 0 to 255 | For possible values, see bits 0 to 7. |
| 16 - 23 | Input B | 0 to 255 | For possible values, see bits 0 to 7. |
| 24 - 31 | Input A | 0 to 255 | For possible values, see bits 0 to 7. |

Bit structure of CfO_ChannelMapping2_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---|
| 0 - 15 | Reserved | 0 | |
| 16 - 23 | Input E3 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 24 - 31 | Input E2 | 0 to 255 | For possible values, see bits 16 to 23. |

Information:

For information about the relationship between the input on the module and the channel name, see section "reACTION function blocks - General".

Scaling the position encoder (rtiABRPos)

Name:

CfO_ScalingUnits_ABR1

CfO_ScalingIncrements_ABR1

An optional gear ratio can be configured using registers "Units" and "Increments". The dividend for scaling is defined in register "Units"; the divisor is defined in register "Increments".

| Data type | Value | Information |
|-----------|--------------------|--|
| UDINT | 0 to 4,294,967,295 | CfO_ScalingUnits_ABR1: Units per interval CfO_ScalingIncrements_ABR1: Increments per interval |

Formula for calculation

$$\text{Gear ratio} = \text{ScalingUnits} / \text{ScalingIncrements}$$
Example 1

ScalingUnits = 1

ScalingIncrements = 1

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 1/1$$

In this example, the ABR position value is output unchanged on output "Pos".

Example 2

ScalingUnits = 10

ScalingIncrements = 4

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 10/4$$

In this example, the ABR position value is multiplied by 2.5 and output on output "Pos".

Information:

The encoder values are calculated internally as INT64 values in 32.32 format. On output "Pos" of function block "rtiABRPos", only the whole number value (INT32) is output for the user. The fixed point decimal places are used internally to calculate a higher resolution.

9.28.2.16.6.5 reACTION - Communication

During runtime, the reACTION program is started and stopped via the program sequence in the CPU. Once the reACTION program has been started, it is executed independently of the program sequence in the CPU.

Controlling the reACTION program

Name:
RTEnable

The reACTION program is started and stopped using this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------|
| 0 | RTEnable | 0 | Stops the reACTION program |
| | | 1 | Starts the reACTION program |
| 1 - 7 | Reserved | - | |

reACTION module status messages

Name:
RTEngineRun
RTCycleTimeOverrun
RTFileInvalid
RTFunctionInvalid
RTInstanceInvalid
RTFileNotLoaded

This register is used to output various status messages.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---|-------|--|
| 0 | RTEngineRun | 0 | reACTION program inactive |
| | | 1 | reACTION program active |
| 1 | RTCycleTimeOverrun | 0 | Configured RT cycle time observed |
| | | 1 | RT cycle time configuration too short |
| 2 - 3 | Reserved | - | |
| 4 | RTFileInvalid Invalid reACTION program preloaded | 0 | reACTION program OK in RAM |
| | | 1 | reACTION program invalid in RAM |
| 5 | RTFunctionInvalid Invalid software function | 0 | reACTION program okay |
| | | 1 | reACTION program requesting invalid function block |
| 6 | RTInstanceInvalid Invalid hardware instance | 0 | reACTION program okay |
| | | 1 | reACTION program requesting invalid I/O |
| 7 | RTFileNotLoaded | 0 | Valid reACTION program in reACTION processor |
| | | 1 | Loaded reACTION program invalid |

Cycle counter for the active reACTION program

Name:
RTCycleCounter

This register shows how many times the reACTION program has been executed.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Cycle time of the active reACTION program

Name:
RTCycleTime

This register shows how much time the reACTION module needs to cycle through the loaded program once.

| Data type | Value |
|-----------|--|
| UINT | The resolution of the value shown is 10 ns: 0 to 655.35 [µs] |

9.28.2.16.6.6 reACTION - Interaction

Once started, the reACTION program in the module runs independently. It reads the mappings of the required inputs and manages the outputs assigned to it. In addition, the reACTION program can interact with the CPU. There are 3 different data point types available for this:

| Data point | Description |
|------------|---|
| PAR | Used to transfer information from the CPU to the reACTION program. Data is transferred cyclically. |
| RES | Used to transfer information from the reACTION program to the CPU. Data is transferred cyclically. |
| VAR | VAR data points are transferred non-cyclically. <ul style="list-style-type: none"> PVAR data points: Information transferred from the CPU to the reACTION program RVAR data points: Feedback from reACTION program to the CPU |

PAR data points

Name:

PAR01 to PAR32

PAR01_Bit1 to PAR32_Bit1

PAR01_Bit2 to PAR32_Bit2

PAR01_Bit3 to PAR32_Bit3

PAR01_Bit4 to PAR32_Bit4

PAR01_Bit5 to PAR32_Bit5

PAR01_Bit6 to PAR32_Bit6

PAR01_Bit7 to PAR32_Bit7

PAR01_Bit8 to PAR32_Bit8

Once enabled, the PAR data points are transported cyclically. They are used to transfer information from the CPU to the reACTION program. They can be used to intervene in the execution of the reACTION program.

Information:

PAR data points DO NOT control the outputs directly!

| Data type | Value |
|---------------|------------------------------------|
| (U)SINT, BOOL | Corresponds to the range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | |
|------------------|--------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Index * 8 + 4095 | PAR01 to PAR32 | (U)SINT | | | • | |
| | PAR01_Bit1 to PAR32_Bit1 | Bit 0 | | | | |
| | PAR01_Bit2 to PAR32_Bit2 | Bit 1 | | | | |
| | PAR01_Bit3 to PAR32_Bit3 | Bit 2 | | | | |
| | PAR01_Bit4 to PAR32_Bit4 | Bit 3 | | | | |
| | PAR01_Bit5 to PAR32_Bit5 | Bit 4 | | | | |
| | PAR01_Bit6 to PAR32_Bit6 | Bit 5 | | | | |
| | PAR01_Bit7 to PAR32_Bit7 | Bit 6 | | | | |
| | PAR01_Bit8 to PAR32_Bit8 | Bit 7 | | | | |
| Index * 8 + 4094 | PAR01 to PAR32 | (U)INT | | | • | |
| Index * 8 + 4092 | PAR01 to PAR32 | (U)DINT | | | • | |

RES data points

Name:

RES01 to RES32

RES01_Bit1 to RES32_Bit1

RES01_Bit2 to RES32_Bit2

RES01_Bit3 to RES32_Bit3

RES01_Bit4 to RES32_Bit4

RES01_Bit5 to RES32_Bit5

RES01_Bit6 to RES32_Bit6

RES01_Bit7 to RES32_Bit7

RES01_Bit8 to RES32_Bit8

Once enabled, the RES data points are transported cyclically. They are used to transfer information from the reACTION program to the CPU. They can be used to monitor execution of the reACTION program.

Information:**RES data points DO NOT map the inputs directly!**

| Data type | Value |
|---------------|------------------------------------|
| (U)SINT, BOOL | Corresponds to the range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | |
|------------------|--------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Index * 8 + 5119 | RES01 to RES32 | (U)SINT | • | | | |
| | RES01_Bit1 to RES32_Bit1 | Bit 0 | | | | |
| | RES01_Bit2 to RES32_Bit2 | Bit 1 | | | | |
| | RES01_Bit3 to RES32_Bit3 | Bit 2 | | | | |
| | RES01_Bit4 to RES32_Bit4 | Bit 3 | | | | |
| | RES01_Bit5 to RES32_Bit5 | Bit 4 | | | | |
| | RES01_Bit6 to RES32_Bit6 | Bit 5 | | | | |
| | RES01_Bit7 to RES32_Bit7 | Bit 6 | | | | |
| | RES01_Bit8 to RES32_Bit8 | Bit 7 | | | | |
| Index * 8 + 5118 | RES01 to RES32 | (U)INT | • | | | |
| Index * 8 + 5116 | RES01 to RES32 | (U)DINT | • | | | |

PVAR and RVAR data points

Name:

PVAR1 to PVAR256

RVAR1 to RVAR256

In addition to PAR and RES data points, PVAR/RVAR data points can also be defined in the reACTION program. They are a direct component of the reACTION program and can be accessed acyclically by the CPU.

Like the PAR and RES data points, the PVAR data points are used to transfer information from the CPU to the reACTION program. The RVAR data points are used to transfer feedback from the reACTION program to the CPU.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

| Register | Name | Data type | Read | | Write | |
|------------------|------------------|-----------|--------|---------|--------|---------|

| Index * 4 + 2044 | RVAR1 to RVAR256 | DINT | | • | | |

9.28.3 X20RT8001

Data sheet version: 1.24

9.28.3.1 General information

This reACTION technology module has four high-speed digital inputs and four high-speed digital mixed channels. All connections are designed for 1-wire connections. All inputs are designed for sink connections, the outputs for push-pull connections.

Ultrafast reACTION Technology makes it possible to control the integrated I/O channels with response times down to 1 μ s. All of the commands that can be used for reACTION programs are provided as function blocks in special libraries (e.g. AsIORTI). Programming in compliance with IEC 61131-3 requirements takes place in the Function Block Diagram editor in Automation Studio.

The module supports blackout mode. In blackout mode, programmable module functionality persists even if the network fails.

- reACTION technology module
- 4 high-speed digital inputs
- 4 high-speed digital channels, configurable as inputs or outputs
- 1 ABR incremental encoder input 24 V
- Pulse width modulation
- 24 VDC and GND for encoder supply
- Supports blackout mode

9.28.3.2 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | reACTION Technology modules |  |
| X20RT8001 | X20 reACTION module, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, reACTION Technology module | |
| | Required accessories | |
| | Bus modules | |

9.28.3.4 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|------------|-----------------------------|------------------|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode or blackout mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | Warning/Error on an I/O channel. Level monitoring of digital outputs has been triggered. |
| | | | Double flash | Supply voltage not in valid range or no reACTION program loaded |
| | | | Triple flash | Test of internal memory failed (limited functionality, module must be replaced) |
| | | | On | Error or reset state (reACTION program using functions or channels that are not permitted on this hardware) |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1, 2, 5, 6 | Green | | Input state of the corresponding digital input |
| | 3, 4, 7, 8 | Green | | Input or output status of the corresponding digital input or output |

Table 597: LED status indicators (X1)

- 1) A firmware update can take several minutes depending on the configuration.

9.28.3.5 Pinout

To prevent crosstalk, each individual signal line should be shielded. The maximum cable length is 20 m.

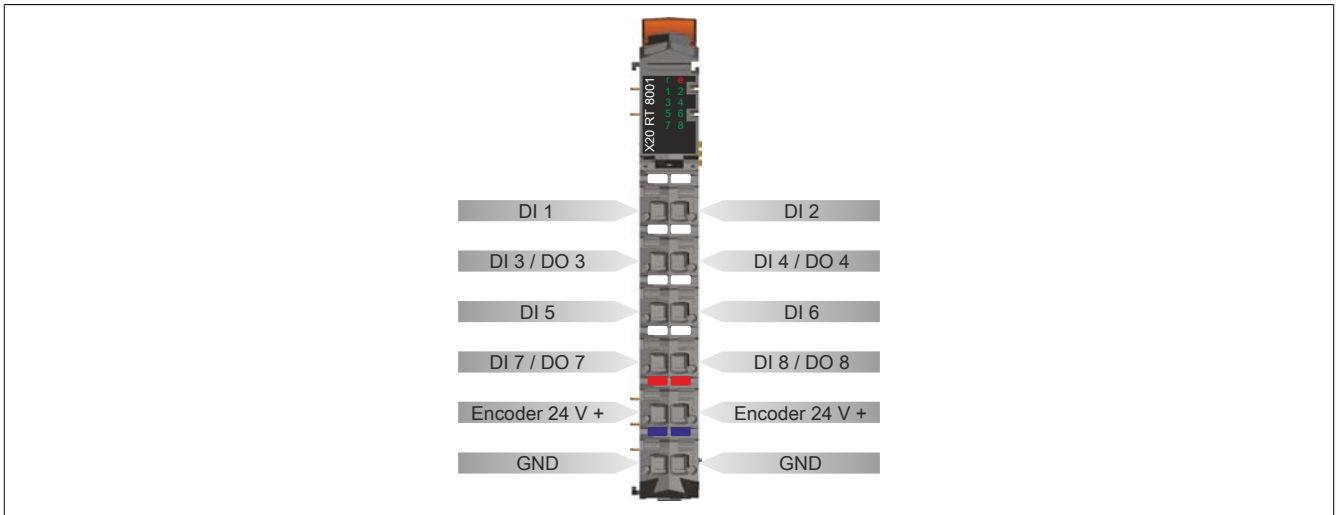

Figure 315: Pinout (X1)

9.28.3.6 Local I/O channels

The following table provides an overview of the connections to the I/O channels.

Digital inputs/outputs

| Connection | Terminal connection | Channel |
|------------|---------------------|-------------|
| X1 | 11 | DI 1 |
| | 21 | DI 2 |
| | 12 | DI 3 / DO 3 |
| | 22 | DI 4 / DO 4 |
| | 13 | DI 5 |
| | 23 | DI 6 |
| | 14 | DI 7 / DO 7 |
| | 24 | DI 8 / DO 8 |

The following section describes assigning I/O channels in a reACTION program:

| I/O channels | Assignment |
|----------------------|--|
| Digital I/O channels | Assignment of digital inputs/outputs |

9.28.3.7 Connection examples

Digital inputs and digital outputs

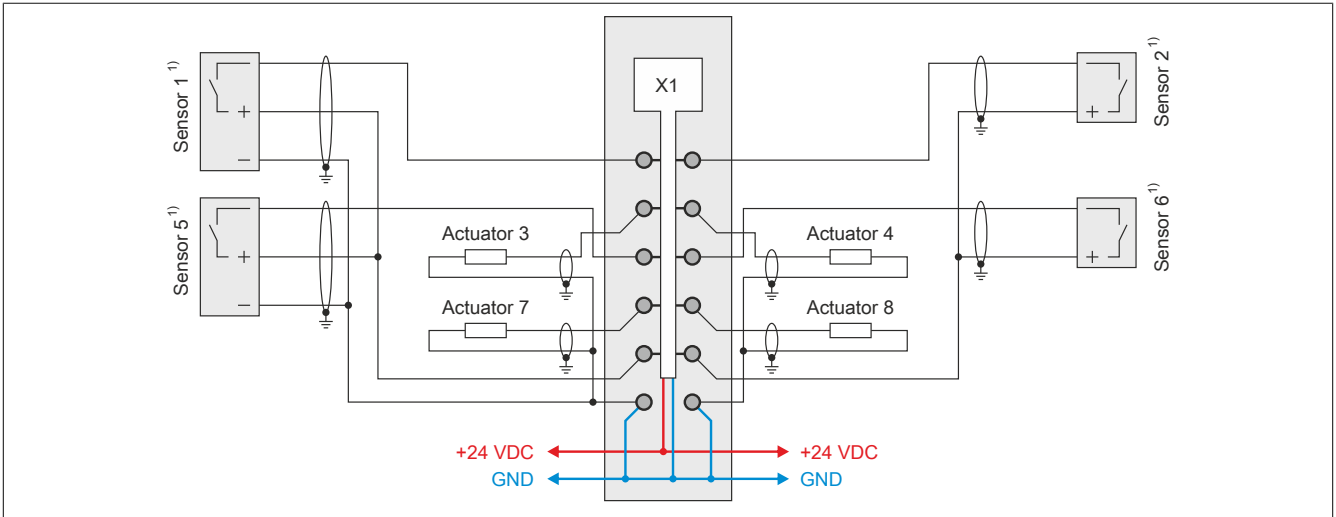

Figure 316: Connection example 1 (X1)

- 1) Observe the wiring guidelines from the sensor manufacturer.

Digital inputs, PWM and ABR incremental encoder

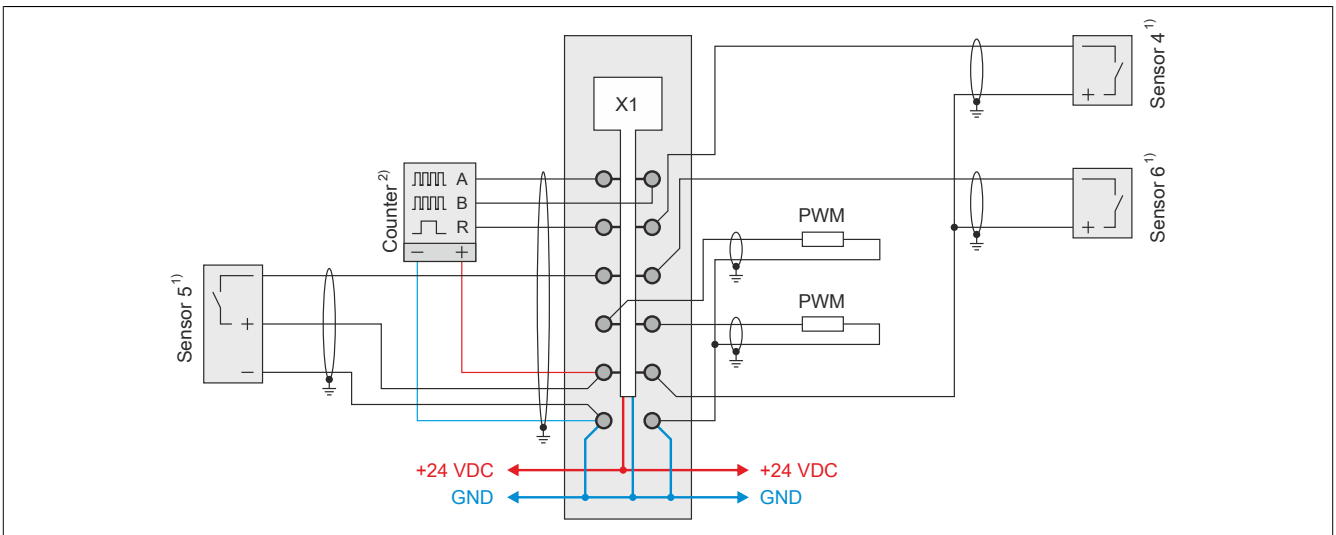

Figure 317: Connection example 2 (X1)

- 1) Observe the wiring guidelines from the sensor manufacturer.
- 2) Observe the wiring guidelines from the encoder manufacturer.

Figure 319: Input/Output circuit diagram of digital mixed channels (X1)

9.28.3.9 Derating and hardware configuration

To ensure proper operation, observe the points listed below:

- Derating of the encoder current
- Number of operable digital outputs
- Hardware configurations

9.28.3.9.1 Derating of the encoder current

Observe the following derating values for the encoder current depending on the mounting orientation:

9.28.3.9.2 Number of operable digital outputs

Depending on the mounting orientation, not all 4 digital outputs of the module can be operated starting at a certain ambient temperature.

Information:

To ensure operation of the module with the ambient temperatures listed below, it is absolutely necessary to disconnect channels.

Reducing the output current per channel does not increase the number of digital output channels that can be operated in the corresponding ambient temperature class.

Horizontal installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <45°C | 4 |
| Starting at 45°C | 3 |
| Starting at 55°C | 2 |

Vertical installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <35°C | 4 |
| Starting at 35°C | 3 |
| Starting at 45°C | 2 |

9.28.3.9.3 Hardware configuration for horizontal installation

9.28.3.9.3.1 Hardware configuration starting at an ambient temperature of 50°C

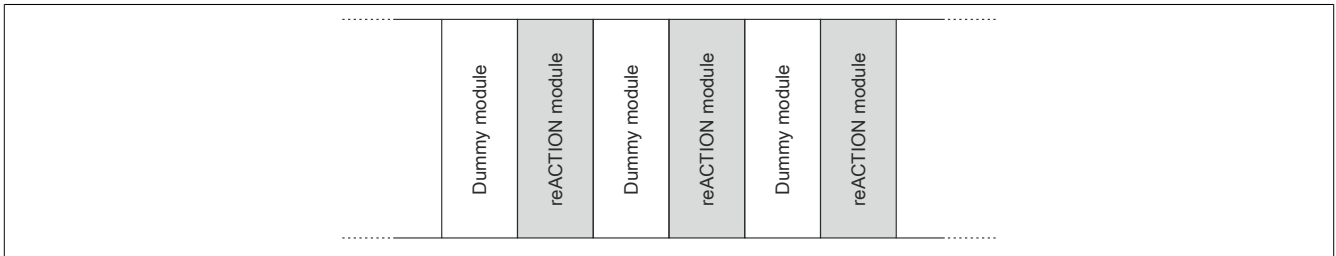

Operating a reACTION module

Starting at an ambient temperature of 50°C, a dummy module must be connected to the left of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.3.9.3.2 Hardware configuration starting at an ambient temperature of 55°C

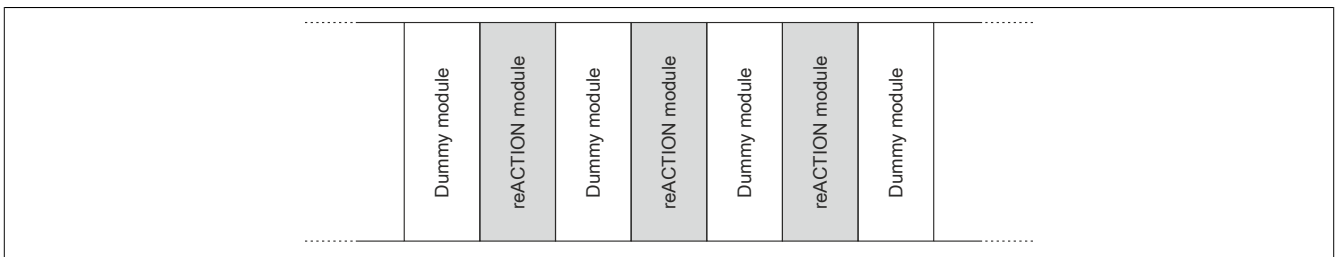

Operating a reACTION module

Starting at an ambient temperature of 55°C, a dummy module must be connected to the left and right of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

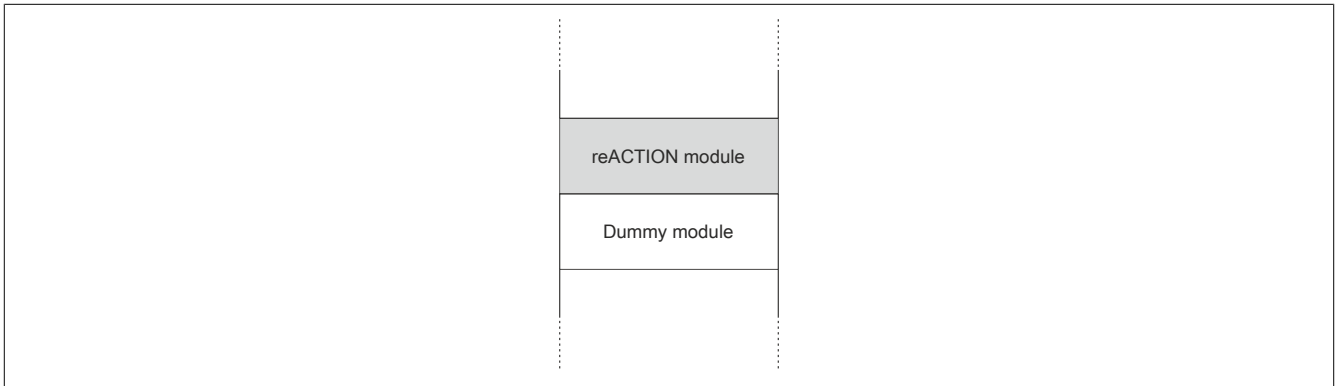

9.28.3.9.4 Hardware configuration for vertical installation

9.28.3.9.4.1 Hardware configuration starting at an ambient temperature of 40°C

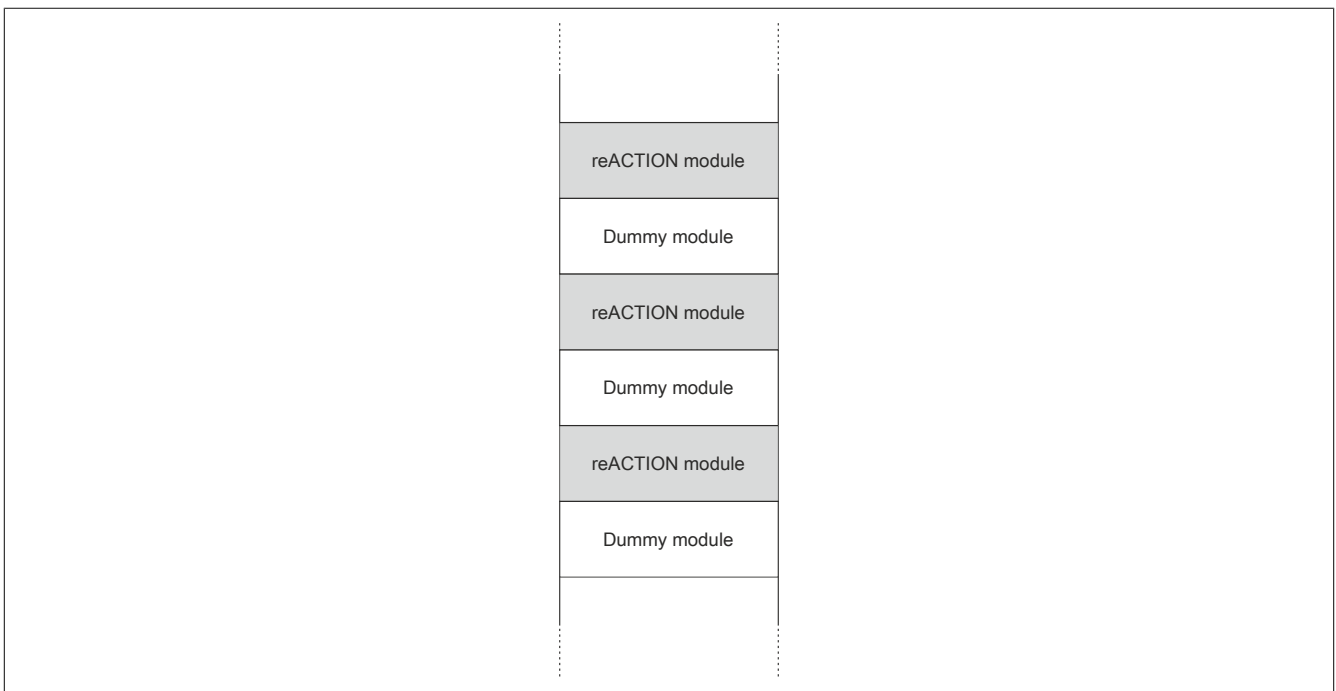

Operating a reACTION module

At ambient temperatures starting at 40°C, a dummy module must be installed below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

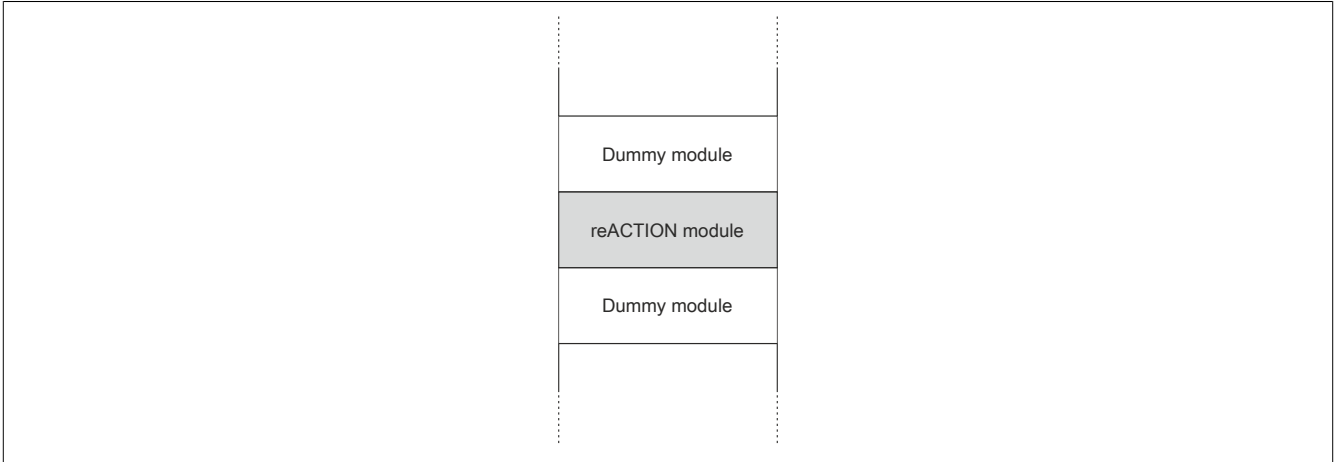

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.3.9.4.2 Hardware configuration starting at an ambient temperature of 45°C

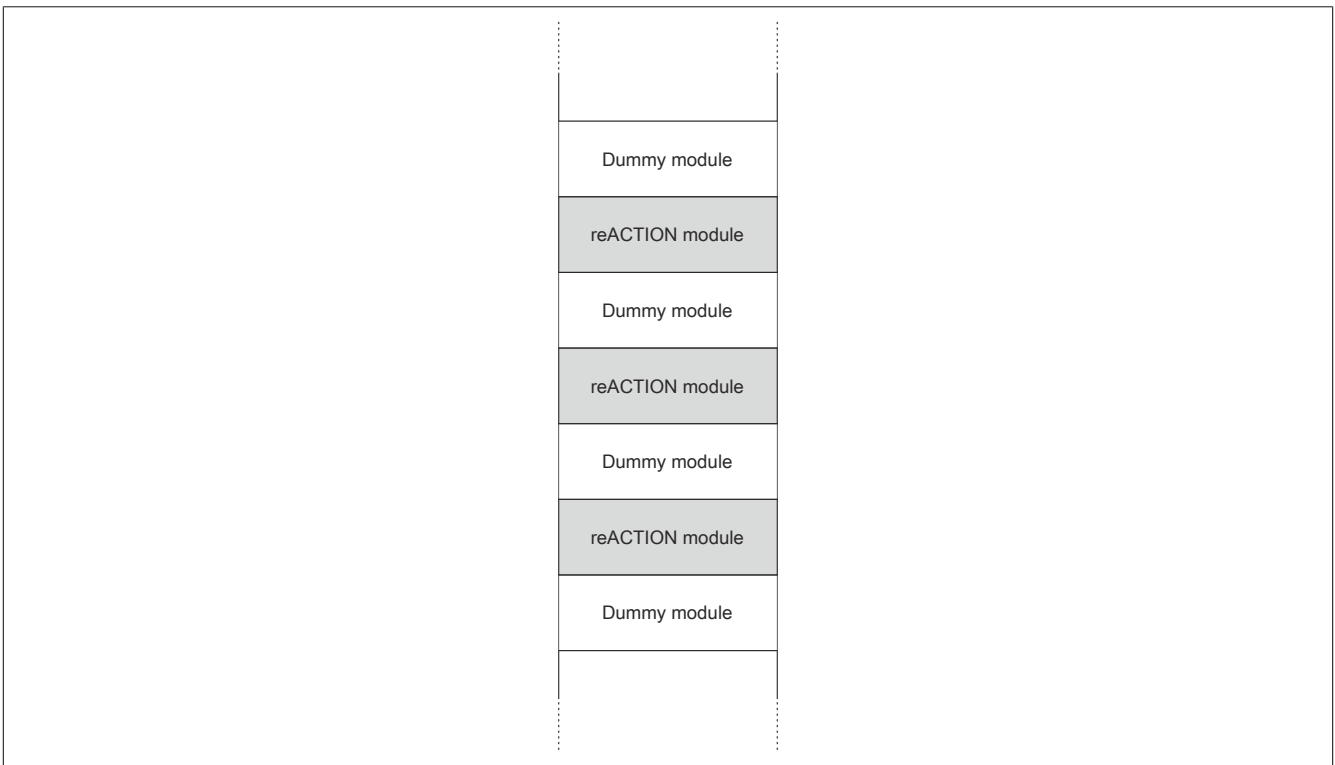

Operating a reACTION module

At ambient temperatures starting at 45°C, dummy modules must be installed above and below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.3.10 Enabling blackout mode

The following steps must be carried out to enable blackout mode.

Requirements

- reACTION program transferred to reACTION module
- Reset triggered on reACTION module:
This ensures that the program stored in the reACTION memory will be loaded with every subsequent reset.

Enabling

- Set the enable register for blackout mode.
- Control bit "RTEnable" must be set. This bit starts the reACTION engine.

Activation

- A connection error triggers a reset on the reACTION module.
- PAR and VAR data points are set to 0.
- Blackout mode is enabled on the reACTION module.

9.28.3.10.1 Blackout mode

For a description of blackout mode, see ["Blackout mode" on page 3794](#).

9.28.3.11 Register description

9.28.3.11.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.28.3.11.2 Function model 0 - "reACTION"

When using the "reACTION" function model, an individual reACTION program must be created for the module. This program will be executed by the reACTION module later on, not by the CPU. This allows individual machine tasks to be managed decentrally and with a very short response time.

The inputs and outputs of a reACTION module can only be operated by an enabled reACTION program. Interaction registers allow information to be exchanged between the CPU and the reACTION program in the module.

In addition to communication with the CPU, the cyclic interaction registers can also be used for "cross-mapping". In this way, inputs/outputs can also be read/controlled by external modules across the entire X2X Link or POWERLINK network.

| Register | Name | Data type | Read | | Write | |
|---------------------------------|--|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module communication | | | | | | |
| 158 | ModuleStatus | UINT | | • | | |

9.28.3.11.3 Function model 254 - "Direct I/O"

In the "Direct I/O" function model, a special reACTION program is executed in the module in order to manage the I/O. In addition, cyclic registers are used to exchange information with the CPU. This reproduces the behavior of a standard module.

| Register | Name | Data type | Read | | Write | |
|---------------------------------|--------------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module communication | | | | | | |
| 129 | Status - Acknowledgment | USINT | | | • | |
| | RTHardwareWarningQuit | Bit 2 | | | | |
| 145 | Status - Composite message | USINT | • | | | |
| | RTHardwareWarning | Bit 2 | | | | |
| 159 | Status word - Module (L byte) | USINT | • | | | |
| | SensorSupplyOk_X1 | Bit 0 | | | | |
| 163 | Status word - Digital (L byte) | USINT | • | | | |
| | DigitalOutput3Overload | Bit 2 | | | | |
| | DigitalOutput4Overload | Bit 3 | | | | |
| | DigitalOutput7Overload | Bit 6 | | | | |
| | DigitalOutput8Overload | Bit 7 | | | | |
| Direct I/O configuration | | | | | | |
| 556 | CfO_DigitalDirection | UDINT | | | | • |
| 548 | CfO_DigitalFilter | UDINT | | | | • |
| Direct I/O communication | | | | | | |
| 5 | Digital outputs | USINT | | | • | |
| | DigitalOutput03 | Bit 2 | | | | |
| | DigitalOutput04 | Bit 3 | | | | |
| | DigitalOutput07 | Bit 6 | | | | |
| | DigitalOutput08 | Bit 7 | | | | |
| 1 | Digital inputs | USINT | • | | | |
| | DigitalInput01 | Bit 0 | | | | |
| | ... | ... | | | | |
| | DigitalInput08 | Bit 7 | | | | |

9.28.3.11.4 Module communication

9.28.3.11.4.1 Module status messages

Name:

ModuleStatus

This register is used to transfer general status messages for the module.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|--------------------------------------|-------------------|-------|-----------------------|
| Status word - Module (L byte) | | | |
| 0 | SensorSupplyOk_X1 | 0 | Encoder supply faulty |
| | | 1 | No error |
| 1 - 7 | Reserved | - | |

9.28.3.11.4.2 Status messages for the digital channels

Name:

DigitalStatus

This register is used to transfer general status messages for the digital channels.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|---------------------------------------|------------------------|-------|---|
| Status word - Digital (L byte) | | | |
| 0 - 1 | Reserved | - | |
| 2 | DigitalOutput3Overload | 0 | Digital output 3 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 3 | DigitalOutput4Overload | 0 | Digital output 4 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 4 - 5 | Reserved | - | |
| 6 | DigitalOutput7Overload | 0 | Digital output 7 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 7 | DigitalOutput8Overload | 0 | Digital output 8 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |

9.28.3.11.5 reACTION - Configuration

9.28.3.11.5.1 reACTION cycle time

Name:

ReActionCycleTimeValue

ReActionCycleTimeMultiplier

Registers "TimeValue" and "Multiplier" predefine the desired cycle time for the reACTION program. Register "TimeValue" contains the value, while register "Multiplier" contains the associated units.

Register "Multiplier" is currently permanently set to 1000 in order to predefine the cycle time with μ s precision.

| Data type | Value |
|-----------|------------|
| UDINT | 1 to 10000 |

9.28.3.11.5.2 Configuring the PAR data points

Name:

CfO_PARType01

CfO_PARType[02...04]

PAR data points can be defined for the reACTION program. To enable them, the desired data type must be made known according to the configuration in Automation Studio.

| Data type | Value |
|-----------|-------------------|
| UDINT | See bit structure |

Bit structure:

| Bit | Name | Value | Information |
|---------|-----------------|-------|-------------|
| 0 - 3 | Type01 - PAR 1 | 0000 | Inactive |
| | Type02 - PAR 9 | 0001 | USINT, BOOL |
| | Type03 - PAR 17 | | |
| | Type04 - PAR 25 | | |
| 4 - 7 | Type01 - PAR 2 | 0010 | UINT |
| | Type02 - PAR 10 | 0011 | UDINT |
| | Type03 - PAR 18 | | |
| | Type04 - PAR 26 | | |
| 8 - 11 | Type01 - PAR 3 | 0100 | Reserved |
| | Type02 - PAR 11 | 0101 | SINT |
| | Type03 - PAR 19 | | |
| | Type04 - PAR 27 | | |
| 12 - 15 | Type01 - PAR 4 | 0110 | INT |
| | Type02 - PAR 12 | 0111 | DINT |
| | Type03 - PAR 20 | | |
| | Type04 - PAR 28 | | |
| 16 - 19 | Type01 - PAR 5 | 1000 | Reserved |
| | Type02 - PAR 13 | ... | |
| | Type03 - PAR 21 | 1111 | |
| | Type04 - PAR 29 | | |
| 20 - 23 | Type01 - PAR 6 | | |
| | Type02 - PAR 14 | | |
| | Type03 - PAR 22 | | |
| | Type04 - PAR 30 | | |
| 24 - 27 | Type01 - PAR 7 | | |
| | Type02 - PAR 15 | | |
| | Type03 - PAR 23 | | |
| | Type04 - PAR 31 | | |
| 28 - 31 | Type01 - PAR 8 | | |
| | Type02 - PAR 16 | | |
| | Type03 - PAR 24 | | |
| | Type04 - PAR 32 | | |

9.28.3.11.6 reACTION - Communication

At runtime, the reACTION module program is controlled via the program sequence in the CPU. In its active state, the reACTION program is then executed independently of the program sequence in the CPU.

9.28.3.11.6.1 Controlling the reACTION module

Name:

RTEnable

RTHardwareWarningQuit

This register controls the reACTION program.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------------|-------|--|
| 0 | RTEnable | 0 | Stops the reACTION program |
| | | 1 | Starts the reACTION program |
| 1 | Reserved | - | |
| 2 | RTHardwareWarningQuit | 0 | No effect |
| | | 1 | Acknowledges warning messages for the inputs and outputs |
| 3 - 7 | Reserved | - | |

9.28.3.11.6.2 reACTION module status messages

Name:

RTEngineRun

RTCycleTimeOverrun

RTHardwareWarning

RTFileInvalid

RTFunctionInvalid

RTInstanceInvalid

RTFileNotLoaded

This register is used to output various status messages.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|---|-------|--|
| 0 | RTEngineRun | 0 | reACTION program inactive |
| | | 1 | reACTION program active |
| 1 | RTCycleTimeOverrun | 0 | Configured RT cycle time observed |
| | | 1 | RT cycle time set too short |
| 2 | RTHardwareWarning (group bit for acyclic status data points) | 0 | No status messages |
| | | 1 | Warning message for the inputs and outputs |
| 3 | Reserved | - | |
| 4 | RTFileInvalid (invalid RT program preloaded) | 0 | RT program in RAM OK |
| | | 1 | RT program in RAM invalid |
| 5 | RTFunctionInvalid (invalid software function) | 0 | RT program OK |
| | | 1 | RT program requesting invalid function block |
| 6 | RTInstanceInvalid (invalid hardware instance) | 0 | RT program OK |
| | | 1 | RT program requesting invalid I/O |
| 7 | RTFileNotLoaded | 0 | Valid RT program in RT engine |
| | | 1 | No RT program loaded |

9.28.3.11.6.3 Cycle counter for the active reACTION program

Name:

RTCycleCounter

Register "CycleCounter" can be used to determine how often the reACTION program has cycled.

| Data type | Value |
|-----------|------------|
| UINT | 0 to 65535 |

9.28.3.11.6.4 Minimum cycle time of the active reACTION program

Name:

RTCycleTime

Register "RTCycleTime" can be used to determine how much time the reACTION module needs to cycle through the loaded program once.

| Data type | Value |
|-----------|-------------------------|
| UINT | 0 to 65535: Units 10 ns |

9.28.3.11.7 reACTION - Interaction

After startup, the reACTION program in the module runs independently. It reads the images of the required inputs and manages its assigned outputs throughout the entire network. In addition, the reACTION program can interact with the CPU. There are 3 different data point types available for this.

9.28.3.11.7.1 PAR data points

Name:

PAR[01...32]
 PAR[01...32]_Bit1
 PAR[01...32]_Bit2
 PAR[01...32]_Bit3
 PAR[01...32]_Bit4
 PAR[01...32]_Bit5
 PAR[01...32]_Bit6
 PAR[01...32]_Bit7
 PAR[01...32]_Bit8

Once enabled, the PAR data points are transported cyclically via X2X Link. They are used to transfer information from the CPU to the reACTION program. They can be used to intervene in the execution of the reACTION program.

Information:

PAR data points DO NOT control the module's outputs directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | |
|------------------|---------------------------------|-----------------------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 4095 + Index * 8 | PAR01 PAR[02...32] | (U)SINT | | | • | |
| | PAR01_Bit1 PAR[02...32]_Bit1 | Bit 0 | | | | |
| | PAR01_Bit2 PAR[02...32]_Bit2 | Bit 1 | | | | |
| | PAR01_Bit3 PAR[02...32]_Bit3 | Bit 2 | | | | |
| | PAR01_Bit4 PAR[02...32]_Bit4 | Bit 3 | | | | |
| | PAR01_Bit5 PAR[02...32]_Bit5 | Bit 4 | | | | |
| | PAR01_Bit6 PAR[02...32]_Bit6 | Bit 5 | | | | |
| | PAR01_Bit7 PAR[02...32]_Bit7 | Bit 6 | | | | |
| | PAR01_Bit8 PAR[02...32]_Bit8 | Bit 7 | | | | |
| | 4094 + Index * 8 | PAR01 PAR[02...32] | (U)INT | | | • |
| 4092 + Index * 8 | PAR01 PAR[02...32] | (U)DINT | | | • | |

9.28.3.11.7.2 RES data points

Name:

RES[01...32]

RES[01...32]_Bit1

RES[01...32]_Bit2

RES[01...32]_Bit3

RES[01...32]_Bit4

RES[01...32]_Bit5

RES[01...32]_Bit6

RES[01...32]_Bit7

RES[01...32]_Bit8

Once enabled, the RES data points are transported cyclically via X2X Link. They are used to transfer information from the reACTION program to the CPU.

Information:

RES data points DO NOT map the module's input directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | |
|-------------------|-------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 5119 + Index * 8 | RES01 | (U)SINT | • | | | |
| | RES[02...32] | | | | | |
| | RES01_Bit1 | Bit 0 | | | | |
| | RES[02...32]_Bit1 | | | | | |
| | RES01_Bit2 | Bit 1 | | | | |
| | RES[02...32]_Bit2 | | | | | |
| | RES01_Bit3 | Bit 2 | | | | |
| | RES[02...32]_Bit3 | | | | | |
| | RES01_Bit4 | Bit 3 | | | | |
| | RES[02...32]_Bit4 | | | | | |
| | RES01_Bit5 | Bit 4 | | | | |
| | RES[02...32]_Bit5 | | | | | |
| | RES01_Bit6 | Bit 5 | | | | |
| RES[02...32]_Bit6 | | | | | | |
| RES01_Bit7 | Bit 6 | | | | | |
| RES[02...32]_Bit7 | | | | | | |
| RES01_Bit8 | Bit 7 | | | | | |
| RES[02...32]_Bit8 | | | | | | |
| 5118 + Index * 8 | RES01 | (U)INT | • | | | |
| | RES[02...32] | | | | | |
| 5116 + Index * 8 | RES01 | (U)DINT | • | | | |
| | RES[02...32] | | | | | |

9.28.3.11.7.3 PVAR and RVAR data points

Name:

PVAR[1...256]

RVAR[1...256]

In addition to PAR and RES data points, VAR data points can also be defined in the reACTION program. They are a direct component of the reACTION program and can be accessed acyclically by the CPU. Like the PAR and RES data points, the PVAR data points are used to transfer information from the CPU to the reACTION program. The RVAR data points are used to transfer feedback from the reACTION program to the CPU.

| Data type | Value |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

| Register | Name | Data type | Read | | Write | |
|------------------|------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 6140 + Index * 8 | PVAR1 PVAR[2...256] | DINT | | | | • |
| 6140 + Index * 8 | RVAR1 RVAR[2...256] | DINT | | • | | |

9.28.3.11.8 reACTION function blocks - General

The following table provides an overview of I/O channel assignments to reACTION function blocks.

Digital inputs/outputs

| Channel | Function block | | |
|-----------------|-----------------------|-----------|----------------------|
| | Mapping ¹⁾ | rtiDin | rtiDout, rtiDoutTime |
| X1: DI 1 | 0x00 | Channel 1 | |
| X1: DI 2 | 0x01 | Channel 2 | |
| X1: DI 3 / DO 3 | 0x02 | Channel 3 | Channel 3 |
| X1: DI 4 / DO 4 | 0x03 | Channel 4 | Channel 4 |
| X1: DI 5 | 0x04 | Channel 5 | |
| X1: DI 6 | 0x05 | Channel 6 | |
| X1: DI 7 / DO 7 | 0x06 | Channel 7 | Channel 7 |
| X1: DI 8 / DO 8 | 0x07 | Channel 8 | Channel 8 |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rtiABRPos) (see ["reACTION function blocks - Configuration" on page 3469](#)).

9.28.3.11.9 reACTION function blocks - Configuration

Some function blocks in library AsIoRti must be configured before they can be used.

| Function block | Information |
|----------------|--|
| rtiABRPos | The module offers the option of using function block rtiABRPos once in the reACTION program. To do so, the function block must be assigned 3 digital inputs that are no longer available for rtiDin. |
| rtiABCnt | The module offers the option of using function block rtiABCnt up to 3 times in the reACTION program. To do so, the function blocks must be assigned 2 digital inputs as an A or B track that are no longer available for rtiDin. In addition, an external event can be defined for each rtiABCnt function block. The input used for this is also no longer available for rtiDin. |

Table 598: List of function blocks requiring prior configuration

9.28.3.11.9.1 Function blocks rtiABRPos and rtiABCnt

Function blocks rtiABRPos and rtiABCnt can be used to process the position value of an ABR incremental encoder in a reACTION task. Several hardware channels of the module are used for this. The incoming signals are interpreted by the reACTION engine and converted into a location.

The update rate depends on both the reACTION engine and the hardware used. The reACTION engine is basically able to calculate positions with an update rate of up to 8 MHz. The input frequencies of the hardware inputs can be taken from the technical data of the respective module.

These function blocks can be used separately or in combination.

Using function block rtiABRPos

The following points are important to keep in mind when using function block rtiABRPos in a reACTION program:

- The function block can only be used once in a reACTION program.
- 3 digital inputs must be defined on the module for input signals A, B and R.
- In addition, a digital input of the module can be defined as an event input.

Example diagram of input signals:

Figure 320: Schematic diagram of input signals for rtiABRPos

Using function block rtiABCnt

The following points must be taken into account when using function block rtiABCnt in a reACTION program:

- The function block can be used up to 3 times in a reACTION program.
- 2 digital inputs must be defined on the module for input signals A and B.
- In addition, up to 3 digital inputs on the module can be defined as event inputs E1, E2 and E3.

Example diagram of input signals:

Figure 321: Schematic diagram of input signals for rtiABCnt

Using function blocks rtiABRPos and rtiABCnt in combination

The following points should be kept in mind when using function blocks rtiABRPos and rtiABCnt together in a reACTION program.

- Function block rtiABRPos can only be used once in a reACTION program.
- Function block rtiABCnt can be used up to 2 times in a reACTION program.
- 3 digital inputs must be defined for input signals A, B and R (rtiABRPos).
- The same digital inputs are used for input signals A and B (rtiABCnt).
- In addition, up to 3 event inputs E1, E2 and E3 can be defined (rtiABCnt).
- E1 is used for the event input (rtiABRPos).

Example diagram of input signals:

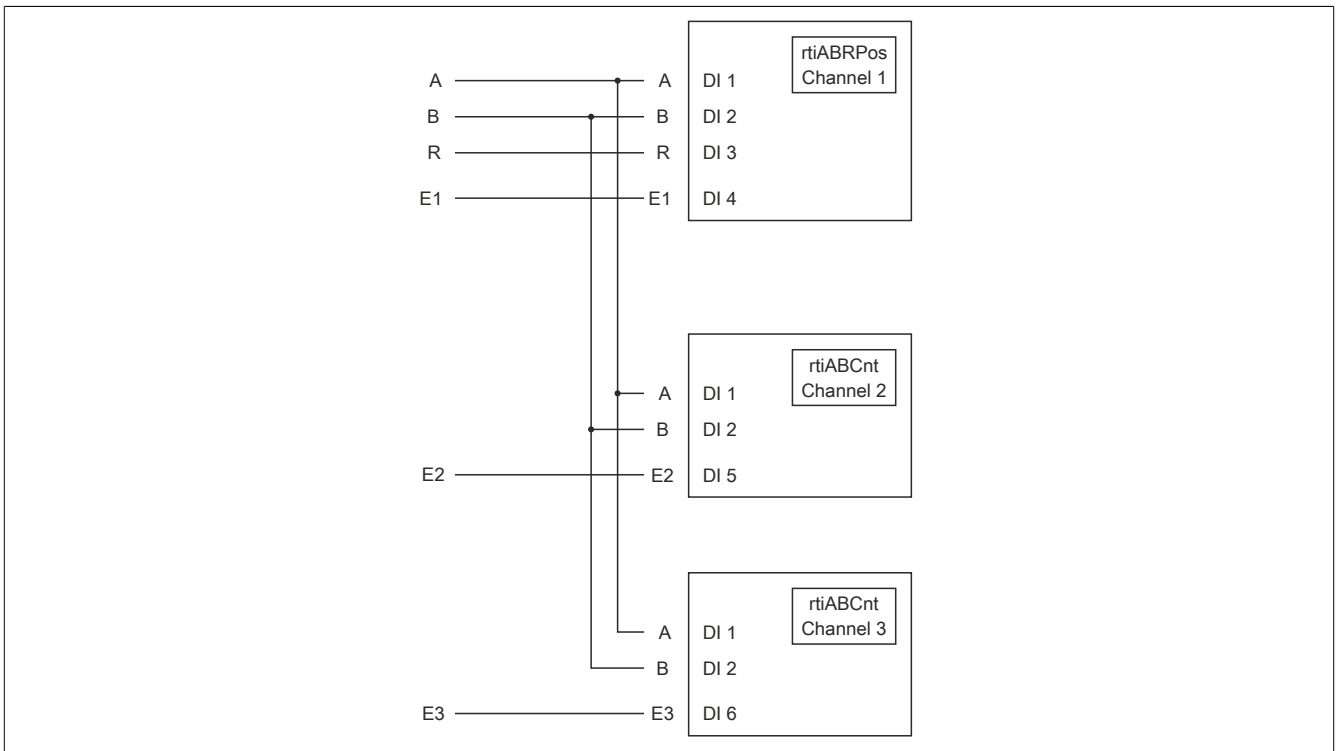

Figure 322: Diagram of input signals when using rtiABRPos and rtiABCnt at the same time

Registering the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_Config_ABR1

This register specifies the technical characteristics of the connected ABR incremental encoder.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|------------|---|
| 0 - 15 | Increments per revolution | 0 to 65535 | Reference pulse monitoring: If the reference pulse is different than defined here, this is indicated on the status output of function block rtiABRPos. |
| 16 | Inversion of the counting direction set by signals A and B | 0 | Positive counting direction |
| | | 1 | Negative counting direction |
| 17 - 31 | Reserved | 0 | |

Wiring the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_ChannelMapping1_ABR1

CfO_ChannelMapping2_ABR1

Before function blocks rtiABRPos/rtiABCnt can be processed by the reACTION engine, the hardware inputs to be used by the ABR incremental encoder must be defined on the module. The "ChannelMapping" registers specify which inputs are interpreted as the A, B, R, E1, E2 and E3 signals.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure of CfO_ChannelMapping1_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---------------------------------------|
| 0 - 7 | Input E1 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 8 - 15 | Input R | 0 to 255 | For possible values, see bits 0 to 7. |
| 16 - 23 | Input B | 0 to 255 | For possible values, see bits 0 to 7. |
| 24 - 31 | Input A | 0 to 255 | For possible values, see bits 0 to 7. |

Bit structure of CfO_ChannelMapping2_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---|
| 0 - 15 | Reserved | 0 | |
| 16 - 23 | Input E3 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 24 - 31 | Input E2 | 0 to 255 | For possible values, see bits 16 to 23. |

Information:

For information about the relationship between the input on the module and the channel name, see section "reACTION function blocks - General".

Scaling the position encoder (rtiABRPos)

Name:

CfO_ScalingUnits_ABR1

CfO_ScalingIncrements_ABR1

An optional gear ratio can be configured using registers "Units" and "Increments". The dividend for scaling is defined in register "Units"; the divisor is defined in register "Increments".

| Data type | Value | Information |
|-----------|--------------------|--|
| UDINT | 0 to 4,294,967,295 | CfO_ScalingUnits_ABR1: Units per interval CfO_ScalingIncrements_ABR1: Increments per interval |

Formula for calculation

$$\text{Gear ratio} = \text{ScalingUnits} / \text{ScalingIncrements}$$
Example 1

ScalingUnits = 1

ScalingIncrements = 1

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 1/1$$

In this example, the ABR position value is output unchanged on output "Pos".

Example 2

ScalingUnits = 10

ScalingIncrements = 4

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 10/4$$

In this example, the ABR position value is multiplied by 2.5 and output on output "Pos".

Information:

The encoder values are calculated internally as INT64 values in 32.32 format. On output "Pos" of function block "rtiABRPos", only the whole number value (INT32) is output for the user. The fixed point decimal places are used internally to calculate a higher resolution.

9.28.3.11.10 Direct I/O configuration

In the "Direct I/O" function model, behavior is based on that of a standard module. The I/O channels are managed by an extremely simplified reACTION program. The function model primarily serves to check that the I/O channels are functioning properly. This module is equipped with 8 digital channels.

9.28.3.11.10.1 Direction of digital channels

Name:

CfO_DigitalDirection

This register determines the signal direction of digital channels 3, 4, 7 and 8.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-------------------------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | Direction - Digital channel 3 | 0 | Input |
| | | 1 | Output |
| 3 | Direction - Digital channel 4 | 0 | Input |
| | | 1 | Output |
| 4 - 5 | Reserved | 0 | |
| 6 | Direction - Digital channel 7 | 0 | Input |
| | | 1 | Output |
| 7 | Direction - Digital channel 8 | 0 | Input |
| | | 1 | Output |

9.28.3.11.10.2 Filtering digital channels

Name:

CfO_DigitalFilter

This register defines the filter time of the digital channels. The filter value affects both the switching delay as well as the immunity of the channels.

| Data type | Value |
|-----------|--------------------------|
| UDINT | 0 to 500000: Units 10 ns |

9.28.3.11.11 Direct I/O communication

This module is equipped with the following inputs and outputs:

- 4 digital inputs (sink) for 24 VDC
- 4 digital channels configurable as inputs (sink) or outputs (sink or source) for 24 VDC

9.28.3.11.11.1 Digital outputs

Name:

DigitalOutput03

DigitalOutput04

DigitalOutput07

DigitalOutput08

This register is used to predefine the value that should be output on the digital output.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | DigitalOutput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalOutput04 | 0 | FALSE |
| | | 1 | TRUE |
| 4 - 5 | Reserved | 0 | |
| 6 | DigitalOutput07 | 0 | FALSE |
| | | 1 | TRUE |
| 7 | DigitalOutput08 | 0 | FALSE |
| | | 1 | TRUE |

9.28.3.11.11.2 Digital inputs

Name:

DigitalInput01

DigitalInput02

DigitalInput03

DigitalInput04

DigitalInput05

DigitalInput06

DigitalInput07

DigitalInput08

This register indicates the value read for the respective digital input.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------|-------|-------------|
| 0 | DigitalInput01 | 0 | FALSE |
| | | 1 | TRUE |
| 1 | DigitalInput02 | 0 | FALSE |
| | | 1 | TRUE |
| 2 | DigitalInput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalInput04 | 0 | FALSE |
| | | 1 | TRUE |
| 4 | DigitalInput05 | 0 | FALSE |
| | | 1 | TRUE |
| 5 | DigitalInput06 | 0 | FALSE |
| | | 1 | TRUE |
| 6 | DigitalInput07 | 0 | FALSE |
| | | 1 | TRUE |
| 7 | DigitalInput08 | 0 | FALSE |
| | | 1 | TRUE |

9.28.3.11.12 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.28.3.11.13 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 200 μ s |

9.28.4 X20RT8201

Data sheet version: 1.14

9.28.4.1 General information

This reACTION technology module has 4 high-speed digital inputs and 4 high-speed digital mixed channels. All connections are designed for 1-wire connections. All inputs are designed for sink connections, the outputs for push-pull connections.

A voltage signal of ± 10 V can be read using 2 analog inputs.

Ultrafast reACTION Technology makes it possible to control the integrated I/O channels with response times down to 1 μ s. All of the commands that can be used for reACTION programs are provided as function blocks in special libraries (e.g. AsIORTI). Programming in compliance with IEC 61131-3 requirements takes place in the Function Block Diagram editor in Automation Studio.

The module supports blackout mode. In blackout mode, programmable module functionality persists even if the network fails.

- reACTION technology module
- 4 high-speed digital inputs
- 4 high-speed digital channels, configurable as inputs or outputs
- 2 high-speed analog inputs ± 10 V
- 1 ABR incremental encoder input 24 V
- Pulse width modulation
- 24 VDC and GND for encoder supply
- Supports blackout mode

9.28.4.2 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | reACTION Technology modules |  |
| X20RT8201 | X20 reACTION module, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, 2 analog inputs ± 10 V, 500 kHz sampling frequency, 13-bit converter resolution including sign, configurable input filter, reACTION Technology module | |
| | Required accessories | |
| | Bus modules | |
| X20BM31 | X20 bus module for double-width modules, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |

Table 600: X20RT8201 - Technical data

- 1) See section "X20 shielding brackets".
- 2) See section "Derating and hardware configuration".
- 3) To reduce power dissipation, B&R recommends bridging unused inputs on the terminal.
- 4) Based on the current measured value.
- 5) Based on the 20 V measurement range.

9.28.4.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|------------|---|------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode or blackout mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | Warning/Error on an I/O channel. Level monitoring of digital outputs has been triggered. |
| | | | Double flash | Supply voltage not in valid range or no reACTION program loaded |
| | | | Triple flash | Test of internal memory failed (limited functionality, module must be replaced) |
| | On | Error or reset state (reACTION program using functions or channels that are not permitted on this hardware) | | |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1, 2, 5, 6 | Green | | Input state of the corresponding digital input |
| | 3, 4, 7, 8 | Green | | Input or output status of the corresponding digital input or output |

Table 601: LED status indicators (X1)

1) A firmware update can take several minutes depending on the configuration.

| Figure | LED | Color | Status | Description |
|--|------|-------|----------|--|
|  | 1, 2 | Green | Off | Open line or disconnected sensor |
| | | | Blinking | Input signal overflow or underflow |
| | | | On | Analog/digital converter running, value OK |
| | | | | |

Table 602: LED status indicators (X2)

9.28.4.5 Pinout

9.28.4.5.1 X1 - Pinout

To prevent crosstalk, each individual signal line should be shielded. The maximum cable length is 20 m.

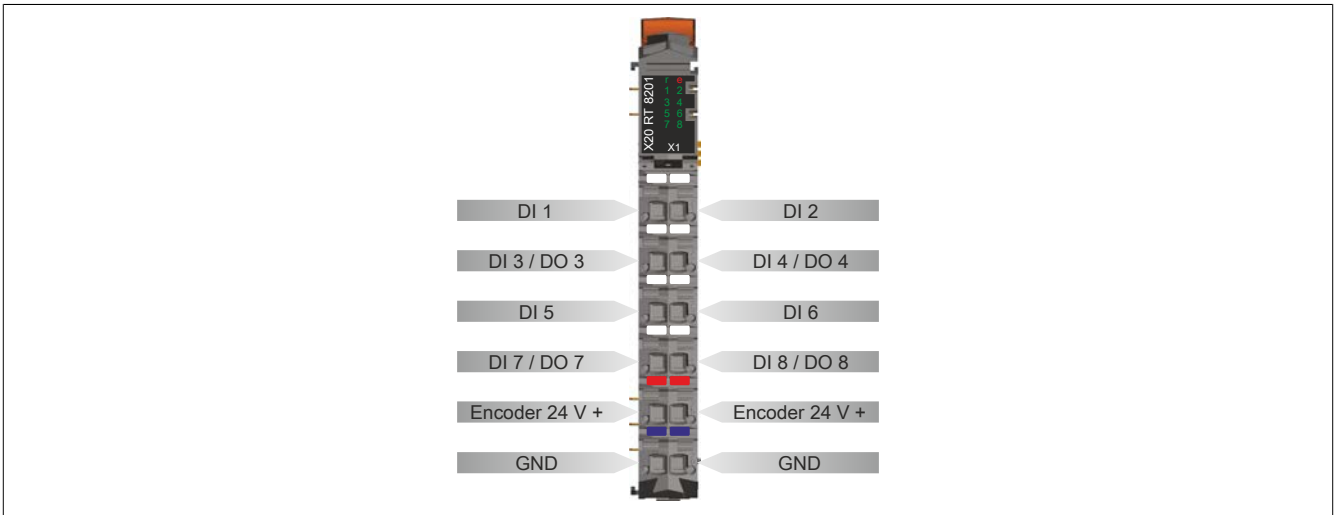

Figure 323: X1 - Pinout

9.28.4.5.2 X2 - Pinout

To prevent crosstalk, each individual signal line should be shielded. The maximum cable length is 20 m.

Figure 324: X2 - Pinout

9.28.4.6 Local I/O channels

The following tables provide an overview of the connections to the I/O channels.

Digital inputs/outputs

| Connection | Terminal connection | Channel |
|------------|---------------------|-------------|
| X1 | 11 | DI 1 |
| | 21 | DI 2 |
| | 12 | DI 3 / DO 3 |
| | 22 | DI 4 / DO 4 |
| | 13 | DI 5 |
| | 23 | DI 6 |
| | 14 | DI 7 / DO 7 |
| | 24 | DI 8 / DO 8 |

Analog inputs

| Connection | Terminal connection | Channel |
|------------|---------------------|---------|
| X2 | 11 and 12 | AI 1 |
| | 21 and 22 | AI 2 |

The following sections describe assigning I/O channels in a reACTION program:

| I/O channels | Assignment |
|-----------------------|--|
| Digital I/O channels | Assignment of digital inputs/outputs |
| Analog input channels | Assignment of analog inputs |

9.28.4.7 Connection examples

9.28.4.7.1 X1 - Connection examples

Digital inputs and digital outputs

9.28.4.9 Derating and hardware configuration

To ensure proper operation, observe the points listed below:

- Derating of the encoder current
- Number of operable digital outputs
- Hardware configurations

9.28.4.9.1 Derating of the encoder current

Observe the following derating values for the encoder current depending on the mounting orientation:

9.28.4.9.2 Number of operable digital outputs

Depending on the mounting orientation, not all 4 digital outputs of the module can be operated starting at a certain ambient temperature.

Information:

To ensure operation of the module with the ambient temperatures listed below, it is absolutely necessary to disconnect channels.

Reducing the output current per channel does not increase the number of digital output channels that can be operated in the corresponding ambient temperature class.

Horizontal installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <45°C | 4 |
| Starting at 45°C | 3 |
| Starting at 55°C | 2 |

Vertical installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <35°C | 4 |
| Starting at 35°C | 3 |
| Starting at 45°C | 2 |

9.28.4.9.3 Hardware configuration for horizontal installation

9.28.4.9.3.1 Hardware configuration starting at an ambient temperature of 50°C

Operating a reACTION module

Starting at an ambient temperature of 50°C, a dummy module must be connected to the left of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.4.9.3.2 Hardware configuration starting at an ambient temperature of 55°C

Operating a reACTION module

Starting at an ambient temperature of 55°C, a dummy module must be connected to the left and right of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.4.9.4 Hardware configuration for vertical installation

9.28.4.9.4.1 Hardware configuration starting at an ambient temperature of 40°C

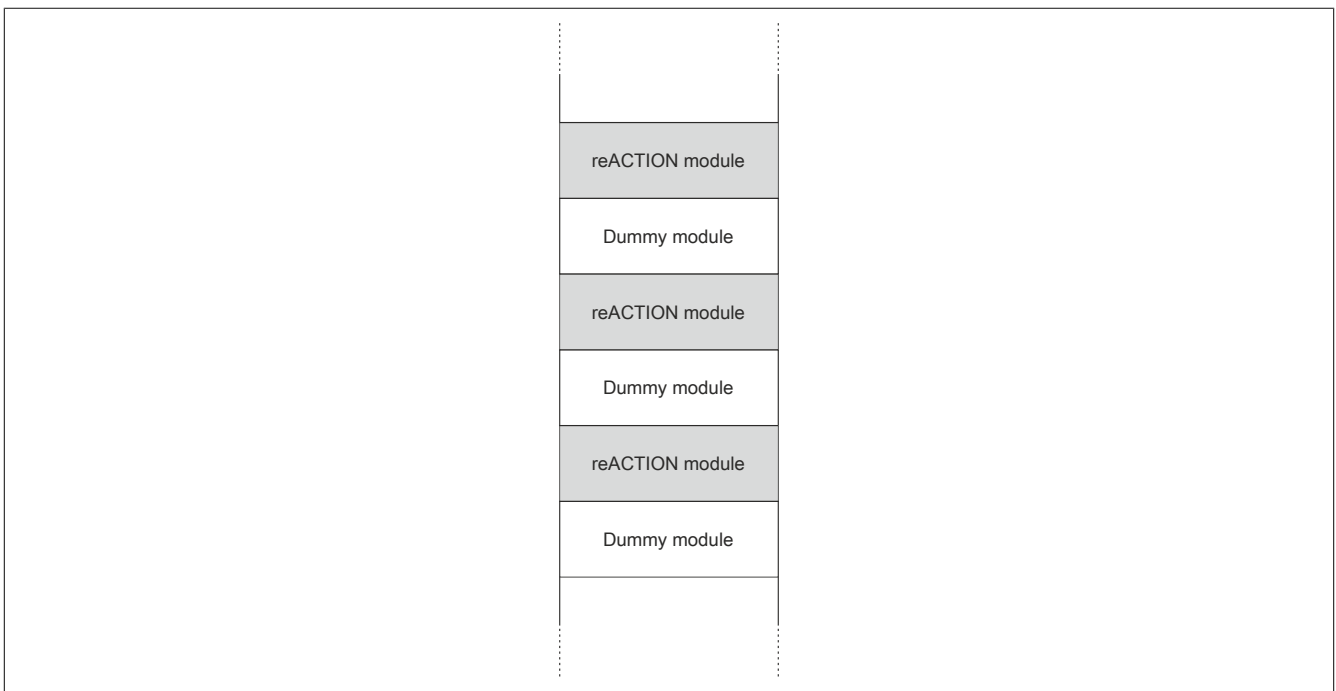

Operating a reACTION module

At ambient temperatures starting at 40°C, a dummy module must be installed below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.4.9.4.2 Hardware configuration starting at an ambient temperature of 45°C

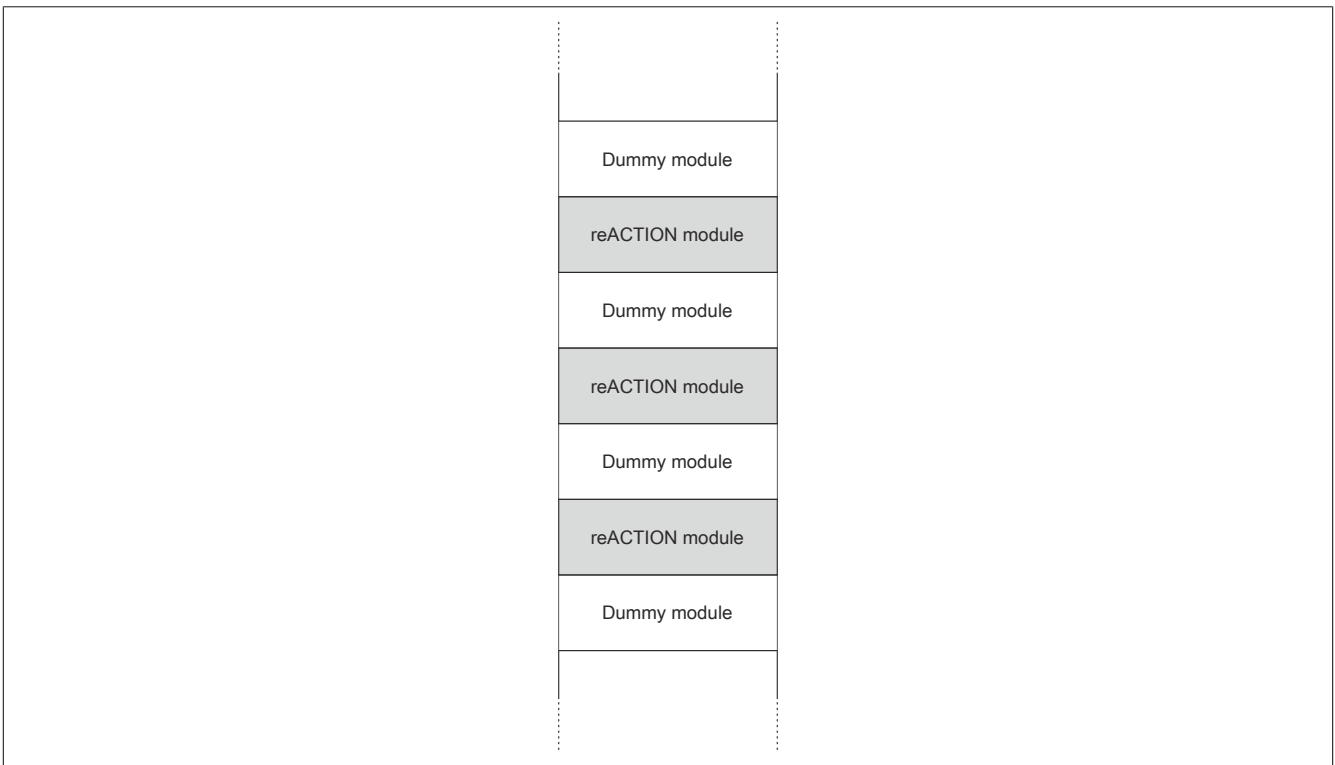

Operating a reACTION module

At ambient temperatures starting at 45°C, dummy modules must be installed above and below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.4.10 Enabling blackout mode

The following steps must be carried out to enable blackout mode.

Requirements

- reACTION program transferred to reACTION module
- Reset triggered on reACTION module:
This ensures that the program stored in the reACTION memory will be loaded with every subsequent reset.

Enabling

- Set the enable register for blackout mode.
- Control bit "RTEnable" must be set. This bit starts the reACTION engine.

Activation

- A connection error triggers a reset on the reACTION module.
- PAR and VAR data points are set to 0.
- Blackout mode is enabled on the reACTION module.

9.28.4.10.1 Blackout mode

For a description of blackout mode, see ["Blackout mode" on page 3794](#).

9.28.4.11 Register description

9.28.4.11.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.28.4.11.2 Function model 0 - "reACTION"

When using the "reACTION" function model, an individual reACTION program must be created for the module. This program will be executed by the reACTION module later on, not by the CPU. This allows individual machine tasks to be managed decentrally and with a very short response time.

The inputs and outputs of a reACTION module can only be operated by an enabled reACTION program. Interaction registers allow information to be exchanged between the CPU and the reACTION program in the module.

In addition to communication with the CPU, the cyclic interaction registers can also be used for "cross-mapping". In this way, inputs/outputs can also be read/controlled by external modules across the entire X2X Link or POWERLINK network.

| Register | Name | Data type | Read | | Write | |
|---------------------------------|--|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module communication | | | | | | |

9.28.4.11.3 Function model 254 - "Direct I/O"

In the "Direct I/O" function model, a special reACTION program is executed in the module in order to manage the I/O. In addition, cyclic registers are used to exchange information with the CPU. This reproduces the behavior of a standard module.

| Register | Name | Data type | Read | | Write | |
|---------------------------------|---------------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module communication | | | | | | |

9.28.4.11.4 Module communication

9.28.4.11.4.1 Module status messages

Name:
ModuleStatus

This register is used to transfer general status messages for the module.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|--------------------------------------|---------------------|-------|---|
| Status word - Module (L byte) | | | |
| 0 | SensorSupplyOk_X1 | 0 | (Encoder) power supply for X1 faulty |
| | | 1 | No error |
| 1 | InternalSupplyOk_X1 | 0 | Internal voltage conversion for X1 faulty |
| | | 1 | No error |
| 2 | SensorSupplyOk_X2 | 0 | Power supply for X2 faulty |
| | | 1 | No error |
| 3 | InternalSupplyOk_X2 | 0 | Internal voltage conversion for X2 faulty |
| | | 1 | No error |
| 4 - 5 | Reserved | - | |
| 6 | X1ToX2ComError | 0 | No error |
| | | 1 | X1 → X2 communication faulty |
| 7 | X2ToX1ComError | 0 | No error |
| | | 1 | X2 → X1 communication faulty |
| Status word - Module (H byte) | | | |
| 0 | AnalogIn01ComError | 0 | No error |
| | | 1 | Value from analog input 1 faulty |
| 1 | AnalogIn02ComError | 0 | No error |
| | | 1 | Value from analog input 2 faulty |
| 2 - 7 | Reserved | - | |

9.28.4.11.4.2 Status messages for the digital channels

Name:
DigitalStatus

This register is used to transfer general status messages for the digital channels.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|---------------------------------------|------------------------|-------|---|
| Status word - Digital (L byte) | | | |
| 0 - 1 | Reserved | - | |
| 2 | DigitalOutput3Overload | 0 | Digital output 3 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 3 | DigitalOutput4Overload | 0 | Digital output 4 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 4 - 5 | Reserved | - | |
| 6 | DigitalOutput7Overload | 0 | Digital output 7 OK |

| 7 | DigitalOutput8Overload | 0 | Digital output 8 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |

9.28.4.11.4.3 Status messages from analog inputs

Name:

AnalogInputStatus

This register transfers general status messages of analog inputs.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|--|---------------------|-------|--|
| Status word - AnalogIn (L byte) | | | |
| 0 | AnalogIn01Underflow | 0 | No error |
| | | 1 | Lower limit value from analog input 1 underrun |
| 1 | AnalogIn01Overflow | 0 | No error |
| | | 1 | Upper limit value from analog input 1 exceeded |
| 2 | AnalogIn01OpenLoop | 0 | No error |
| | | 1 | Open line determined on analog input 1 |
| 3 - 7 | Reserved | - | |
| Status word - AnalogIn (H byte) | | | |
| 0 | AnalogIn02Underflow | 0 | No error |
| | | 1 | Lower limit value from analog input 2 underrun |
| 1 | AnalogIn02Overflow | 0 | No error |
| | | 1 | Upper limit value from analog input 2 exceeded |
| 2 | AnalogIn02OpenLoop | 0 | No error |
| | | 1 | Open line determined on analog input 2 |
| 3 - 7 | Reserved | - | |

9.28.4.11.5 reACTION - Configuration

9.28.4.11.5.1 reACTION cycle time

Name:

ReActionCycleTimeValue

ReActionCycleTimeMultiplier

Registers "TimeValue" and "Multiplier" predefine the desired cycle time for the reACTION program. Register "TimeValue" contains the value, while register "Multiplier" contains the associated units.

Register "Multiplier" is currently permanently set to 1000 in order to predefine the cycle time with μ s precision.

| Data type | Value |
|-----------|------------|
| UDINT | 1 to 10000 |

9.28.4.11.5.2 Configuring the PAR data points

Name:

CfO_PARType01

CfO_PARType[02...04]

PAR data points can be defined for the reACTION program. To enable them, the desired data type must be made known according to the configuration in Automation Studio.

| Data type | Value |
|-----------|-------------------|
| UDINT | See bit structure |

Bit structure:

| Bit | Name | Value | Information |
|---------|-----------------|-------|-------------|
| 0 - 3 | Type01 - PAR 1 | 0000 | Inactive |
| | Type02 - PAR 9 | 0001 | USINT, BOOL |
| | Type03 - PAR 17 | | |
| | Type04 - PAR 25 | | |
| 4 - 7 | Type01 - PAR 2 | | |
| | Type02 - PAR 10 | 0011 | UDINT |
| | Type03 - PAR 18 | | |
| | Type04 - PAR 26 | | |
| 8 - 11 | Type01 - PAR 3 | | |
| | Type02 - PAR 11 | 0101 | SINT |
| | Type03 - PAR 19 | | |
| | Type04 - PAR 27 | | |
| 12 - 15 | Type01 - PAR 4 | | |
| | Type02 - PAR 12 | 0111 | DINT |
| | Type03 - PAR 20 | | |
| | Type04 - PAR 28 | | |
| 16 - 19 | Type01 - PAR 5 | | |
| | Type02 - PAR 13 | ... | |
| | Type03 - PAR 21 | 1111 | |
| | Type04 - PAR 29 | | |
| 20 - 23 | Type01 - PAR 6 | | |
| | Type02 - PAR 14 | | |
| | Type03 - PAR 22 | | |
| | Type04 - PAR 30 | | |
| 24 - 27 | Type01 - PAR 7 | | |
| | Type02 - PAR 15 | | |
| | Type03 - PAR 23 | | |
| | Type04 - PAR 31 | | |
| 28 - 31 | Type01 - PAR 8 | | |
| | Type02 - PAR 16 | | |
| | Type03 - PAR 24 | | |
| | Type04 - PAR 32 | | |

9.28.4.11.6 reACTION - Communication

At runtime, the reACTION module program is controlled via the program sequence in the CPU. In its active state, the reACTION program is then executed independently of the program sequence in the CPU.

9.28.4.11.6.1 Controlling the reACTION module

Name:

RTEnable

RTHardwareWarningQuit

This register controls the reACTION program.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------------|-------|--|
| 0 | RTEnable | 0 | Stops the reACTION program |
| | | 1 | Starts the reACTION program |
| 1 | Reserved | - | |
| 2 | RTHardwareWarningQuit | 0 | No effect |
| | | 1 | Acknowledges warning messages for the inputs and outputs |
| 3 - 7 | Reserved | - | |

9.28.4.11.6.2 reACTION module status messages

Name:

RTEngineRun

RTCycleTimeOverrun

RTHardwareWarning

RTFileInvalid

RTFunctionInvalid

RTInstanceInvalid

RTFileNotLoaded

This register is used to output various status messages.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|---|-------|--|
| 0 | RTEngineRun | 0 | reACTION program inactive |
| | | 1 | reACTION program active |
| 1 | RTCycleTimeOverrun | 0 | Configured RT cycle time observed |
| | | 1 | RT cycle time set too short |
| 2 | RTHardwareWarning (group bit for acyclic status data points) | 0 | No status messages |
| | | 1 | Warning message for the inputs and outputs |
| 3 | Reserved | - | |
| 4 | RTFileInvalid (invalid RT program preloaded) | 0 | RT program in RAM OK |
| | | 1 | RT program in RAM invalid |
| 5 | RTFunctionInvalid (invalid software function) | 0 | RT program OK |
| | | 1 | RT program requesting invalid function block |
| 6 | RTInstanceInvalid (invalid hardware instance) | 0 | RT program OK |
| | | 1 | RT program requesting invalid I/O |
| 7 | RTFileNotLoaded | 0 | Valid RT program in RT engine |
| | | 1 | No RT program loaded |

9.28.4.11.6.3 Cycle counter for the active reACTION program

Name:

RTCycleCounter

Register "CycleCounter" can be used to determine how often the reACTION program has cycled.

| Data type | Value |
|-----------|------------|
| UINT | 0 to 65535 |

9.28.4.11.6.4 Minimum cycle time of the active reACTION program

Name:

RTCycleTime

Register "RTCycleTime" can be used to determine how much time the reACTION module needs to cycle through the loaded program once.

| Data type | Value |
|-----------|-------------------------|
| UINT | 0 to 65535: Units 10 ns |

9.28.4.11.7 reACTION - Interaction

After startup, the reACTION program in the module runs independently. It reads the images of the required inputs and manages its assigned outputs throughout the entire network. In addition, the reACTION program can interact with the CPU. There are 3 different data point types available for this.

9.28.4.11.7.1 PAR data points

Name:

PAR[01...32]

PAR[01...32]_Bit1

PAR[01...32]_Bit2

PAR[01...32]_Bit3

PAR[01...32]_Bit4

PAR[01...32]_Bit5

PAR[01...32]_Bit6

PAR[01...32]_Bit7

PAR[01...32]_Bit8

Once enabled, the PAR data points are transported cyclically via X2X Link. They are used to transfer information from the CPU to the reACTION program. They can be used to intervene in the execution of the reACTION program.

Information:

PAR data points DO NOT control the module's outputs directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | | |
|------------------|---------------------------------|-----------------------|---------|---------|--------|---------|--|
| | | | Cyclic | Acyclic | Cyclic | Acyclic | |
| 4095 + Index * 8 | PAR01 PAR[02...32] | (U)SINT | | | • | | |
| | PAR01_Bit1 PAR[02...32]_Bit1 | Bit 0 | | | | | |
| | PAR01_Bit2 PAR[02...32]_Bit2 | Bit 1 | | | | | |
| | PAR01_Bit3 PAR[02...32]_Bit3 | Bit 2 | | | | | |
| | PAR01_Bit4 PAR[02...32]_Bit4 | Bit 3 | | | | | |
| | PAR01_Bit5 PAR[02...32]_Bit5 | Bit 4 | | | | | |
| | PAR01_Bit6 PAR[02...32]_Bit6 | Bit 5 | | | | | |
| | PAR01_Bit7 PAR[02...32]_Bit7 | Bit 6 | | | | | |
| | PAR01_Bit8 PAR[02...32]_Bit8 | Bit 7 | | | | | |
| | 4094 + Index * 8 | PAR01 PAR[02...32] | (U)INT | | | • | |
| | 4092 + Index * 8 | PAR01 PAR[02...32] | (U)DINT | | | • | |

9.28.4.11.7.2 RES data points

Name:

RES[01...32]

RES[01...32]_Bit1

RES[01...32]_Bit2

RES[01...32]_Bit3

RES[01...32]_Bit4

RES[01...32]_Bit5

RES[01...32]_Bit6

RES[01...32]_Bit7

RES[01...32]_Bit8

Once enabled, the RES data points are transported cyclically via X2X Link. They are used to transfer information from the reACTION program to the CPU.

Information:

RES data points DO NOT map the module's input directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | |
|-------------------|-------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 5119 + Index * 8 | RES01 | (U)SINT | • | | | |
| | RES[02...32] | | | | | |
| | RES01_Bit1 | Bit 0 | | | | |
| | RES[02...32]_Bit1 | | | | | |
| | RES01_Bit2 | Bit 1 | | | | |
| | RES[02...32]_Bit2 | | | | | |
| | RES01_Bit3 | Bit 2 | | | | |
| | RES[02...32]_Bit3 | | | | | |
| | RES01_Bit4 | Bit 3 | | | | |
| | RES[02...32]_Bit4 | | | | | |
| | RES01_Bit5 | Bit 4 | | | | |
| | RES[02...32]_Bit5 | | | | | |
| | RES01_Bit6 | Bit 5 | | | | |
| RES[02...32]_Bit6 | | | | | | |
| RES01_Bit7 | Bit 6 | | | | | |
| RES[02...32]_Bit7 | | | | | | |
| RES01_Bit8 | Bit 7 | | | | | |
| RES[02...32]_Bit8 | | | | | | |
| 5118 + Index * 8 | RES01 | (U)INT | • | | | |
| | RES[02...32] | | | | | |
| 5116 + Index * 8 | RES01 | (U)DINT | • | | | |
| | RES[02...32] | | | | | |

9.28.4.11.7.3 PVAR and RVAR data points

Name:

PVAR[1...256]

RVAR[1...256]

In addition to PAR and RES data points, VAR data points can also be defined in the reACTION program. They are a direct component of the reACTION program and can be accessed acyclically by the CPU. Like the PAR and RES data points, the PVAR data points are used to transfer information from the CPU to the reACTION program. The RVAR data points are used to transfer feedback from the reACTION program to the CPU.

| Data type | Value |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

| Register | Name | Data type | Read | | Write | |
|------------------|------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 6140 + Index * 8 | PVAR1 PVAR[2...256] | DINT | | | | • |
| 6140 + Index * 8 | RVAR1 RVAR[2...256] | DINT | | • | | |

9.28.4.11.8 reACTION function blocks - General

The following tables provide an overview of I/O channel assignments to reACTION function blocks.

Digital inputs/outputs

| Channel | Function block | | |
|-----------------|-----------------------|-----------|----------------------|
| | Mapping ¹⁾ | rTiDin | rTiDout, rTiDoutTime |
| X1: DI 1 | 0x00 | Channel 1 | |
| X1: DI 2 | 0x01 | Channel 2 | |
| X1: DI 3 / DO 3 | 0x02 | Channel 3 | Channel 3 |
| X1: DI 4 / DO 4 | 0x03 | Channel 4 | Channel 4 |
| X1: DI 5 | 0x04 | Channel 5 | |
| X1: DI 6 | 0x05 | Channel 6 | |
| X1: DI 7 / DO 7 | 0x06 | Channel 7 | Channel 7 |
| X1: DI 8 / DO 8 | 0x07 | Channel 8 | Channel 8 |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see ["reACTION function blocks - Configuration" on page 3502](#)).

Analog inputs

| Channel | Function block | | |
|----------|-----------------------|-----------|---------|
| | Mapping ¹⁾ | rTiAin | rTiAout |
| X2: AI 1 | 0x00 | Channel 1 | |
| X2: AI 2 | 0x01 | Channel 2 | |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see ["reACTION function blocks - Configuration" on page 3502](#)).

9.28.4.11.9 reACTION function blocks - Configuration

Some function blocks in library AsIoRti must be configured before they can be used.

| Function block | Information |
|----------------|--|
| rtiABRPos | The module offers the option of using function block rtiABRPos once in the reACTION program. To do so, the function block must be assigned 3 digital inputs that are no longer available for rtiDin. |
| rtiABCnt | The module offers the option of using function block rtiABCnt up to 3 times in the reACTION program. To do so, the function blocks must be assigned 2 digital inputs as an A or B track that are no longer available for rtiDin. In addition, an external event can be defined for each rtiABCnt function block. The input used for this is also no longer available for rtiDin. |

Table 603: List of function blocks requiring prior configuration

9.28.4.11.9.1 Function blocks rtiABRPos and rtiABCnt

Function blocks rtiABRPos and rtiABCnt can be used to process the position value of an ABR incremental encoder in a reACTION task. Several hardware channels of the module are used for this. The incoming signals are interpreted by the reACTION engine and converted into a location.

The update rate depends on both the reACTION engine and the hardware used. The reACTION engine is basically able to calculate positions with an update rate of up to 8 MHz. The input frequencies of the hardware inputs can be taken from the technical data of the respective module.

These function blocks can be used separately or in combination.

Using function block rtiABRPos

The following points are important to keep in mind when using function block rtiABRPos in a reACTION program:

- The function block can only be used once in a reACTION program.
- 3 digital inputs must be defined on the module for input signals A, B and R.
- In addition, a digital input of the module can be defined as an event input.

Example diagram of input signals:

Figure 331: Schematic diagram of input signals for rtiABRPos

Using function block rtiABCnt

The following points must be taken into account when using function block rtiABCnt in a reACTION program:

- The function block can be used up to 3 times in a reACTION program.
- 2 digital inputs must be defined on the module for input signals A and B.
- In addition, up to 3 digital inputs on the module can be defined as event inputs E1, E2 and E3.

Example diagram of input signals:

Figure 332: Schematic diagram of input signals for rtiABCnt

Using function blocks rtiABRPos and rtiABCnt in combination

The following points should be kept in mind when using function blocks rtiABRPos and rtiABCnt together in a reACTION program.

- Function block rtiABRPos can only be used once in a reACTION program.
- Function block rtiABCnt can be used up to 2 times in a reACTION program.
- 3 digital inputs must be defined for input signals A, B and R (rtiABRPos).
- The same digital inputs are used for input signals A and B (rtiABCnt).
- In addition, up to 3 event inputs E1, E2 and E3 can be defined (rtiABCnt).
- E1 is used for the event input (rtiABRPos).

Example diagram of input signals:

Figure 333: Diagram of input signals when using rtiABRPos and rtiABCnt at the same time

Registering the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_Config_ABR1

This register specifies the technical characteristics of the connected ABR incremental encoder.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|------------|---|
| 0 - 15 | Increments per revolution | 0 to 65535 | Reference pulse monitoring: If the reference pulse is different than defined here, this is indicated on the status output of function block rtiABRPos. |
| 16 | Inversion of the counting direction set by signals A and B | 0 | Positive counting direction |
| | | 1 | Negative counting direction |
| 17 - 31 | Reserved | 0 | |

Wiring the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_ChannelMapping1_ABR1

CfO_ChannelMapping2_ABR1

Before function blocks rtiABRPos/rtiABCnt can be processed by the reACTION engine, the hardware inputs to be used by the ABR incremental encoder must be defined on the module. The "ChannelMapping" registers specify which inputs are interpreted as the A, B, R, E1, E2 and E3 signals.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure of CfO_ChannelMapping1_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---------------------------------------|
| 0 - 7 | Input E1 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 8 - 15 | Input R | 0 to 255 | For possible values, see bits 0 to 7. |
| 16 - 23 | Input B | 0 to 255 | For possible values, see bits 0 to 7. |
| 24 - 31 | Input A | 0 to 255 | For possible values, see bits 0 to 7. |

Bit structure of CfO_ChannelMapping2_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---|
| 0 - 15 | Reserved | 0 | |
| 16 - 23 | Input E3 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 24 - 31 | Input E2 | 0 to 255 | For possible values, see bits 16 to 23. |

Information:

For information about the relationship between the input on the module and the channel name, see section "reACTION function blocks - General".

Scaling the position encoder (rtiABRPos)

Name:

CfO_ScalingUnits_ABR1

CfO_ScalingIncrements_ABR1

An optional gear ratio can be configured using registers "Units" and "Increments". The dividend for scaling is defined in register "Units"; the divisor is defined in register "Increments".

| Data type | Value | Information |
|-----------|--------------------|--|
| UDINT | 0 to 4,294,967,295 | CfO_ScalingUnits_ABR1: Units per interval CfO_ScalingIncrements_ABR1: Increments per interval |

Formula for calculation

$$\text{Gear ratio} = \text{ScalingUnits} / \text{ScalingIncrements}$$
Example 1

ScalingUnits = 1

ScalingIncrements = 1

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 1/1$$

In this example, the ABR position value is output unchanged on output "Pos".

Example 2

ScalingUnits = 10

ScalingIncrements = 4

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 10/4$$

In this example, the ABR position value is multiplied by 2.5 and output on output "Pos".

Information:

The encoder values are calculated internally as INT64 values in 32.32 format. On output "Pos" of function block "rtiABRPos", only the whole number value (INT32) is output for the user. The fixed point decimal places are used internally to calculate a higher resolution.

9.28.4.11.10 Direct I/O configuration

This module is equipped with 8 digital channels and 2 analog inputs. In the "Direct I/O" function model, behavior is based on that of a standard module. The I/O channels are managed by an extremely simplified reACTION program. The function model primarily serves to check that the I/O channels are functioning properly.

9.28.4.11.10.1 Direction of digital channels

Name:

CfO_DigitalDirection

This register determines the signal direction of digital channels 3, 4, 7 and 8.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-------------------------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | Direction - Digital channel 3 | 0 | Input |
| | | 1 | Output |
| 3 | Direction - Digital channel 4 | 0 | Input |
| | | 1 | Output |
| 4 - 5 | Reserved | 0 | |
| 6 | Direction - Digital channel 7 | 0 | Input |
| | | 1 | Output |
| 7 | Direction - Digital channel 8 | 0 | Input |
| | | 1 | Output |

9.28.4.11.10.2 Filtering digital channels

Name:

CfO_DigitalFilter

This register defines the filter time of the digital channels. The filter value affects both the switching delay as well as the immunity of the channels.

| Data type | Value |
|-----------|--------------------------|
| UDINT | 0 to 500000: Units 10 ns |

9.28.4.11.10.3 Filtering analog channels

Name:

CfO_AnalogFilter01

CfO_AnalogFilter02

This register sets the filter level of the corresponding analog channel.

| Data type | Value |
|-----------|--------|
| UDINT | 0 to 7 |

$$2^{\text{AnalogFilter}} = \text{FilterLevel} = \frac{\text{Out(ADC)}_t - \text{Out(Filter)}_{t-1}}{\text{Out(Filter)}_t - \text{Out(Filter)}_{t-1}} \cong \frac{\Delta \text{Out(ADC)}}{\Delta \text{Out(Filter)}}$$

The filter level results as the exponent to base 2 and corresponds to the ratio of the change of the digitalized input value to the change of the filtered analog value.

9.28.4.11.10.4 Limit values of analog channels

Name:

CfO_LowerLimit01

CfO_LowerLimit02

CfO_UpperLimit01

CfO_UpperLimit02

These registers define the upper and lower user-specific limit values for analog inputs.

| Data type | Value |
|-----------|---|
| DINT | LowerLimit: -32767 to 32767 (default: -32767) |
| | UpperLimit: -32767 to 32767 (default: 32767) |

9.28.4.11.11 Direct I/O communication

This module is equipped with the following inputs and outputs:

- 4 digital inputs (sink) for 24 VDC
- 4 digital channels configurable as inputs (sink) or outputs (sink or source) for 24 VDC
- 2 analog inputs of type ± 10 V

9.28.4.11.11.1 Digital outputs

Name:

DigitalOutput03

DigitalOutput04

DigitalOutput07

DigitalOutput08

This register is used to predefine the value that should be output on the digital output.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | DigitalOutput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalOutput04 | 0 | FALSE |
| | | 1 | TRUE |
| 4 - 5 | Reserved | 0 | |
| 6 | DigitalOutput07 | 0 | FALSE |
| | | 1 | TRUE |
| 7 | DigitalOutput08 | 0 | FALSE |
| | | 1 | TRUE |

9.28.4.11.11.2 Digital inputs

Name:

DigitalInput01

DigitalInput02

DigitalInput03

DigitalInput04

DigitalInput05

DigitalInput06

DigitalInput07

DigitalInput08

This register indicates the value read for the respective digital input.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------|-------|-------------|
| 0 | DigitalInput01 | 0 | FALSE |
| | | 1 | TRUE |
| 1 | DigitalInput02 | 0 | FALSE |
| | | 1 | TRUE |
| 2 | DigitalInput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalInput04 | 0 | FALSE |
| | | 1 | TRUE |
| 4 | DigitalInput05 | 0 | FALSE |
| | | 1 | TRUE |
| 5 | DigitalInput06 | 0 | FALSE |
| | | 1 | TRUE |
| 6 | DigitalInput07 | 0 | FALSE |
| | | 1 | TRUE |
| 7 | DigitalInput08 | 0 | FALSE |
| | | 1 | TRUE |

9.28.4.11.11.3 Analog inputs

Name:

AnalogInput01

AnalogInput02

The analog input value is mapped in this register.

| Data type | Value |
|-----------|-----------------|
| INT | -32767 to 32767 |

9.28.4.11.12 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.28.4.11.13 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 200 μ s |

9.28.5 X20RT8202

Data sheet version: 1.14

9.28.5.1 General information

This reACTION technology module has 4 high-speed digital inputs and 4 high-speed digital mixed channels. All connections are designed for 1-wire connections. All inputs are designed for sink connections, the outputs for push-pull connections.

A voltage signal of ± 10 V can be output using 2 analog outputs.

Ultrafast reACTION Technology makes it possible to control the integrated I/O channels with response times down to 1 μ s. All of the commands that can be used for reACTION programs are provided as function blocks in special libraries (e.g. AsIORTI). Programming in compliance with IEC 61131-3 requirements takes place in the Function Block Diagram editor in Automation Studio.

The module supports blackout mode. In blackout mode, programmable module functionality persists even if the network fails.

- reACTION technology module
- 4 high-speed digital inputs
- 4 high-speed digital channels, configurable as inputs or outputs
- 2 high-speed analog outputs ± 10 V
- 1 ABR incremental encoder input 24 V
- Pulse width modulation
- 24 VDC and GND for encoder supply
- Supports blackout mode

9.28.5.2 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | reACTION Technology modules |  |
| X20RT8202 | X20 reACTION module, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, 2 analog outputs ± 10 V, 2 μ s, 13-bit converter resolution including sign, reACTION Technology module | |
| | Required accessories | |
| | Bus modules | |
| X20BM31 | X20 bus module for double-width modules, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |

- 5) Based on the output range.

9.28.5.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|------------|-----------------------------|---|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode or blackout mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | Warning/Error on an I/O channel. Level monitoring of digital outputs has been triggered. |
| | | | Double flash | Supply voltage not in valid range or no reACTION program loaded |
| | | | Triple flash | Test of internal memory failed (limited functionality, module must be replaced) |
| | | On | Error or reset state (reACTION program using functions or channels that are not permitted on this hardware) | |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1, 2, 5, 6 | Green | | Input state of the corresponding digital input |
| 3, 4, 7, 8 | Green | | Input or output status of the corresponding digital input or output | |

Table 606: LED status indicators (X1)

1) A firmware update can take several minutes depending on the configuration.

| Figure | LED | Color | Status | Description |
|--|------|--------|--------|-------------|
|  | 1, 2 | Orange | Off | Value = 0 |
| | | | On | Value ≠ 0 |

Table 607: LED status indicators (X2)

9.28.5.5 Pinout

9.28.5.5.1 X1 - Pinout

To prevent crosstalk, each individual signal line should be shielded. The maximum cable length is 20 m.

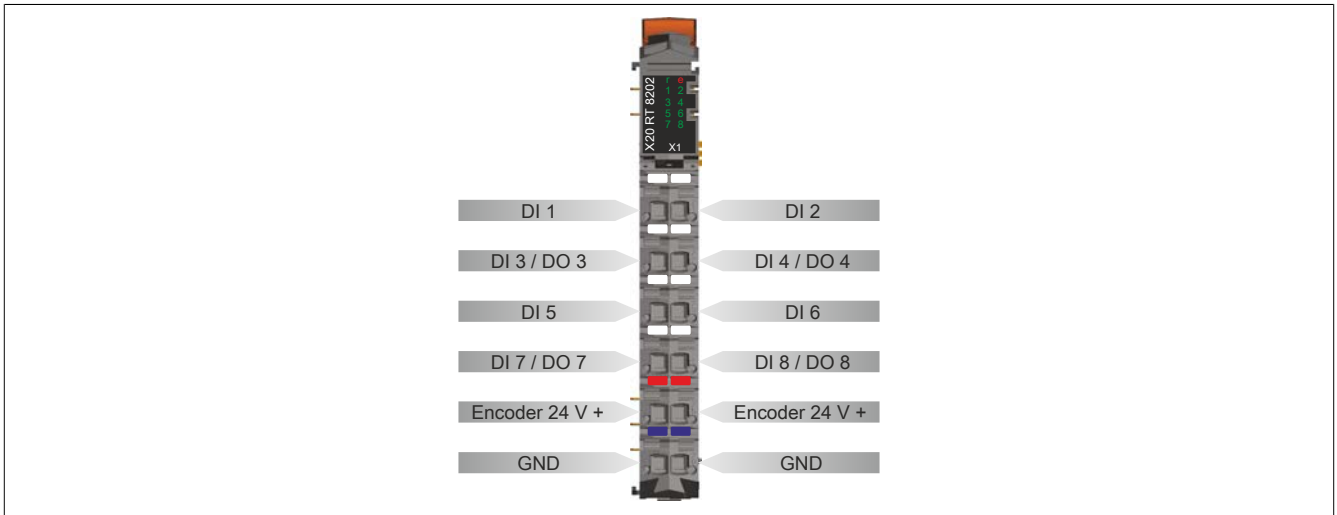

Figure 334: X1 - Pinout

9.28.5.5.2 X2 - Pinout

To prevent crosstalk, each individual signal line should be shielded. The maximum cable length is 20 m.

Figure 335: X2 - Pinout

9.28.5.6 Local I/O channels

The following tables provide an overview of the connections to the I/O channels.

Digital inputs/outputs

| Connection | Terminal connection | Channel |
|------------|---------------------|-------------|
| X1 | 11 | DI 1 |
| | 21 | DI 2 |
| | 12 | DI 3 / DO 3 |
| | 22 | DI 4 / DO 4 |
| | 13 | DI 5 |
| | 23 | DI 6 |
| | 14 | DI 7 / DO 7 |
| | 24 | DI 8 / DO 8 |

Analog outputs

| Connection | Terminal connection | Channel |
|------------|---------------------|---------|
| X2 | 13 and 14 | AO 1 |
| | 23 and 24 | AO 2 |

The following sections describe assigning I/O channels in a reACTION program:

| I/O channels | Assignment |
|------------------------|--|
| Digital I/O channels | Assignment of digital inputs/outputs |
| Analog output channels | Assignment of analog outputs |

9.28.5.9 Derating and hardware configuration

To ensure proper operation, observe the points listed below:

- Derating of the encoder current
- Number of operable digital outputs
- Hardware configurations

9.28.5.9.1 Derating of the encoder current

Observe the following derating values for the encoder current depending on the mounting orientation:

9.28.5.9.2 Number of operable digital outputs

Depending on the mounting orientation, not all 4 digital outputs of the module can be operated starting at a certain ambient temperature.

Information:

To ensure operation of the module with the ambient temperatures listed below, it is absolutely necessary to disconnect channels.

Reducing the output current per channel does not increase the number of digital output channels that can be operated in the corresponding ambient temperature class.

Horizontal installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <45°C | 4 |
| Starting at 45°C | 3 |
| Starting at 55°C | 2 |

Vertical installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <35°C | 4 |
| Starting at 35°C | 3 |
| Starting at 45°C | 2 |

9.28.5.9.3 Hardware configuration for horizontal installation

9.28.5.9.3.1 Hardware configuration starting at an ambient temperature of 50°C

Operating a reACTION module

Starting at an ambient temperature of 50°C, a dummy module must be connected to the left of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.5.9.3.2 Hardware configuration starting at an ambient temperature of 55°C

Operating a reACTION module

Starting at an ambient temperature of 55°C, a dummy module must be connected to the left and right of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

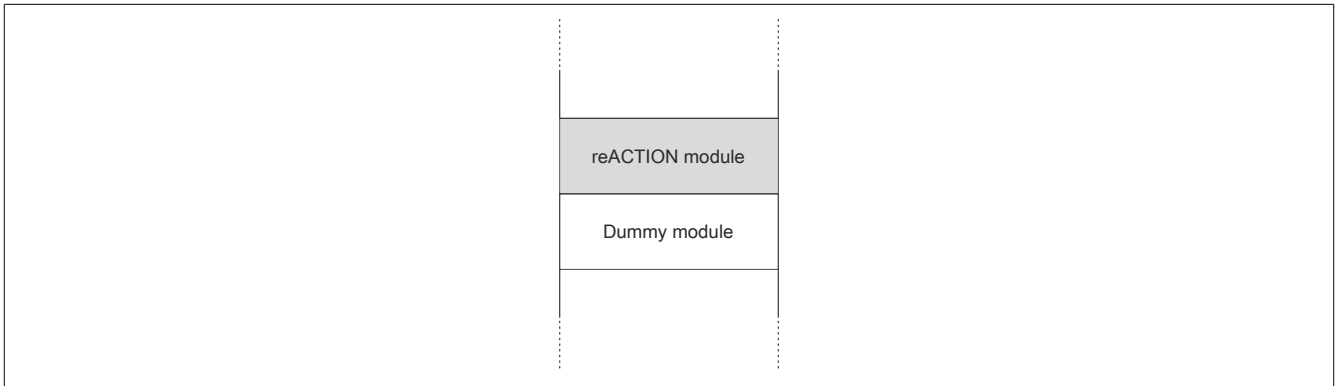

9.28.5.9.4 Hardware configuration for vertical installation

9.28.5.9.4.1 Hardware configuration starting at an ambient temperature of 40°C

Operating a reACTION module

At ambient temperatures starting at 40°C, a dummy module must be installed below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

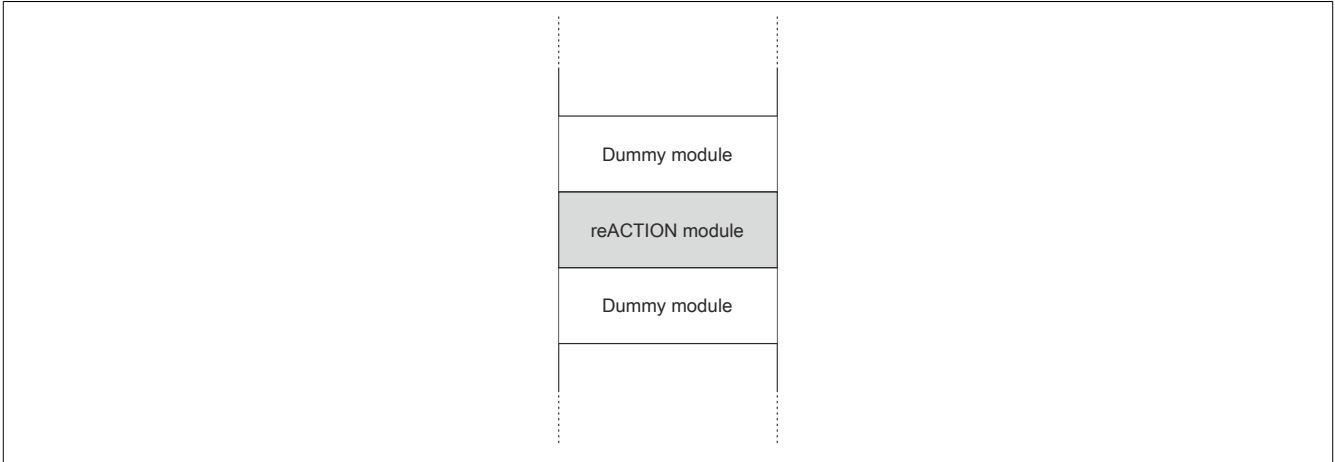

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.5.9.4.2 Hardware configuration starting at an ambient temperature of 45°C

Operating a reACTION module

At ambient temperatures starting at 45°C, dummy modules must be installed above and below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.5.10 Enabling blackout mode

The following steps must be carried out to enable blackout mode.

Requirements

- reACTION program transferred to reACTION module
- Reset triggered on reACTION module:
This ensures that the program stored in the reACTION memory will be loaded with every subsequent reset.

Enabling

- Set the enable register for blackout mode.
- Control bit "RTEnable" must be set. This bit starts the reACTION engine.

Activation

- A connection error triggers a reset on the reACTION module.
- PAR and VAR data points are set to 0.
- Blackout mode is enabled on the reACTION module.

9.28.5.10.1 Blackout mode

For a description of blackout mode, see ["Blackout mode" on page 3794](#).

9.28.5.11 Register description

9.28.5.11.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.28.5.11.2 Function model 0 - "reACTION"

When using the "reACTION" function model, an individual reACTION program must be created for the module. This program will be executed by the reACTION module later on, not by the CPU. This allows individual machine tasks to be managed decentrally and with a very short response time.

The inputs and outputs of a reACTION module can only be operated by an enabled reACTION program. Interaction registers allow information to be exchanged between the CPU and the reACTION program in the module.

In addition to communication with the CPU, the cyclic interaction registers can also be used for "cross-mapping". In this way, inputs/outputs can also be read/controlled by external modules across the entire X2X Link or POWERLINK network.

| Register | Name | Data type | Read | | Write | |

9.28.5.11.3 Function model 254 - "Direct I/O"

In the "Direct I/O" function model, a special reACTION program is executed in the module in order to manage the I/O. In addition, cyclic registers are used to exchange information with the CPU. This reproduces the behavior of a standard module.

| Register | Name | Data type | Read | | Write | |

9.28.5.11.4 Module communication

9.28.5.11.4.1 Module status messages

Name:

ModuleStatus

This register is used to transfer general status messages for the module.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|--------------------------------------|---------------------|-------|---|
| Status word - Module (L byte) | | | |
| 0 | SensorSupplyOk_X1 | 0 | (Encoder) power supply for X1 faulty |
| | | 1 | No error |
| 1 | InternalSupplyOk_X1 | 0 | Internal voltage conversion for X1 faulty |
| | | 1 | No error |
| 2 | SensorSupplyOk_X2 | 0 | Power supply for X2 faulty |
| | | 1 | No error |
| 3 | InternalSupplyOk_X2 | 0 | Internal voltage conversion for X2 faulty |
| | | 1 | No error |
| 4 - 5 | Reserved | - | |
| 6 | X1ToX2ComError | 0 | No error |
| | | 1 | X1 → X2 communication faulty |
| 7 | X2ToX1ComError | 0 | No error |
| | | 1 | X2 → X1 communication faulty |
| Status word - Module (H byte) | | | |
| 0 - 3 | Reserved | - | |
| 4 | AnalogOut01ComError | 0 | No error |
| | | 1 | Value from analog output 1 faulty |
| 5 | AnalogOut02ComError | 0 | No error |
| | | 1 | Value from analog output 2 faulty |
| 6 - 7 | Reserved | - | |

9.28.5.11.4.2 Status messages for the digital channels

Name:

DigitalStatus

This register is used to transfer general status messages for the digital channels.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|---------------------------------------|------------------------|-------|---|
| Status word - Digital (L byte) | | | |
| 0 - 1 | Reserved | - | |
| 2 | DigitalOutput3Overload | 0 | Digital output 3 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 3 | DigitalOutput4Overload | 0 | Digital output 4 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 4 - 5 | Reserved | - | |
| 6 | DigitalOutput7Overload | 0 | Digital output 7 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 7 | DigitalOutput8Overload | 0 | Digital output 8 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |

9.28.5.11.5 reACTION - Configuration**9.28.5.11.5.1 reACTION cycle time**

Name:

ReActionCycleTimeValue

ReActionCycleTimeMultiplier

Registers "TimeValue" and "Multiplier" predefine the desired cycle time for the reACTION program. Register "TimeValue" contains the value, while register "Multiplier" contains the associated units.

Register "Multiplier" is currently permanently set to 1000 in order to predefine the cycle time with μ s precision.

| Data type | Value |
|-----------|------------|
| UDINT | 1 to 10000 |

9.28.5.11.5.2 Configuring the PAR data points

Name:

CfO_PARType01

CfO_PARType[02...04]

PAR data points can be defined for the reACTION program. To enable them, the desired data type must be made known according to the configuration in Automation Studio.

| Data type | Value |
|-----------|-------------------|
| UDINT | See bit structure |

Bit structure:

| Bit | Name | Value | Information |
|---------|-----------------|-------|-------------|
| 0 - 3 | Type01 - PAR 1 | 0000 | Inactive |
| | Type02 - PAR 9 | 0001 | USINT, BOOL |
| | Type03 - PAR 17 | | |
| | Type04 - PAR 25 | | |
| 4 - 7 | Type01 - PAR 2 | 0010 | UINT |
| | Type02 - PAR 10 | 0011 | UDINT |
| | Type03 - PAR 18 | | |
| | Type04 - PAR 26 | | |
| 8 - 11 | Type01 - PAR 3 | 0100 | Reserved |
| | Type02 - PAR 11 | 0101 | SINT |
| | Type03 - PAR 19 | | |
| | Type04 - PAR 27 | | |
| 12 - 15 | Type01 - PAR 4 | 0110 | INT |
| | Type02 - PAR 12 | 0111 | DINT |
| | Type03 - PAR 20 | | |
| | Type04 - PAR 28 | | |
| 16 - 19 | Type01 - PAR 5 | 1000 | Reserved |
| | Type02 - PAR 13 | ... | |
| | Type03 - PAR 21 | 1111 | |
| | Type04 - PAR 29 | | |
| 20 - 23 | Type01 - PAR 6 | | |
| | Type02 - PAR 14 | | |
| | Type03 - PAR 22 | | |
| | Type04 - PAR 30 | | |
| 24 - 27 | Type01 - PAR 7 | | |
| | Type02 - PAR 15 | | |
| | Type03 - PAR 23 | | |
| | Type04 - PAR 31 | | |
| 28 - 31 | Type01 - PAR 8 | | |
| | Type02 - PAR 16 | | |
| | Type03 - PAR 24 | | |
| | Type04 - PAR 32 | | |

9.28.5.11.6 reACTION - Communication

At runtime, the reACTION module program is controlled via the program sequence in the CPU. In its active state, the reACTION program is then executed independently of the program sequence in the CPU.

9.28.5.11.6.1 Controlling the reACTION module

Name:

RTEnable

RTHardwareWarningQuit

This register controls the reACTION program.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------------|-------|--|
| 0 | RTEnable | 0 | Stops the reACTION program |
| | | 1 | Starts the reACTION program |
| 1 | Reserved | - | |
| 2 | RTHardwareWarningQuit | 0 | No effect |
| | | 1 | Acknowledges warning messages for the inputs and outputs |
| 3 - 7 | Reserved | - | |

9.28.5.11.6.2 reACTION module status messages

Name:

RTEngineRun

RTCycleTimeOverrun

RTHardwareWarning

RTFileInvalid

RTFunctionInvalid

RTInstanceInvalid

RTFileNotLoaded

This register is used to output various status messages.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|---|-------|--|
| 0 | RTEngineRun | 0 | reACTION program inactive |
| | | 1 | reACTION program active |
| 1 | RTCycleTimeOverrun | 0 | Configured RT cycle time observed |
| | | 1 | RT cycle time set too short |
| 2 | RTHardwareWarning (group bit for acyclic status data points) | 0 | No status messages |
| | | 1 | Warning message for the inputs and outputs |
| 3 | Reserved | - | |
| 4 | RTFileInvalid (invalid RT program preloaded) | 0 | RT program in RAM OK |
| | | 1 | RT program in RAM invalid |
| 5 | RTFunctionInvalid (invalid software function) | 0 | RT program OK |
| | | 1 | RT program requesting invalid function block |
| 6 | RTInstanceInvalid (invalid hardware instance) | 0 | RT program OK |
| | | 1 | RT program requesting invalid I/O |
| 7 | RTFileNotLoaded | 0 | Valid RT program in RT engine |
| | | 1 | No RT program loaded |

9.28.5.11.6.3 Cycle counter for the active reACTION program

Name:

RTCycleCounter

Register "CycleCounter" can be used to determine how often the reACTION program has cycled.

| Data type | Value |
|-----------|------------|
| UINT | 0 to 65535 |

9.28.5.11.6.4 Minimum cycle time of the active reACTION program

Name:

RTCycleTime

Register "RTCycleTime" can be used to determine how much time the reACTION module needs to cycle through the loaded program once.

| Data type | Value |
|-----------|-------------------------|
| UINT | 0 to 65535: Units 10 ns |

9.28.5.11.7 reACTION - Interaction

After startup, the reACTION program in the module runs independently. It reads the images of the required inputs and manages its assigned outputs throughout the entire network. In addition, the reACTION program can interact with the CPU. There are 3 different data point types available for this.

9.28.5.11.7.1 PAR data points

Name:

PAR[01...32]
 PAR[01...32]_Bit1
 PAR[01...32]_Bit2
 PAR[01...32]_Bit3
 PAR[01...32]_Bit4
 PAR[01...32]_Bit5
 PAR[01...32]_Bit6
 PAR[01...32]_Bit7
 PAR[01...32]_Bit8

Once enabled, the PAR data points are transported cyclically via X2X Link. They are used to transfer information from the CPU to the reACTION program. They can be used to intervene in the execution of the reACTION program.

Information:

PAR data points DO NOT control the module's outputs directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | | |
|------------------|---------------------------------|-----------------------|---------|---------|--------|---------|--|
| | | | Cyclic | Acyclic | Cyclic | Acyclic | |
| 4095 + Index * 8 | PAR01 PAR[02...32] | (U)SINT | | | • | | |
| | PAR01_Bit1 PAR[02...32]_Bit1 | Bit 0 | | | | | |
| | PAR01_Bit2 PAR[02...32]_Bit2 | Bit 1 | | | | | |
| | PAR01_Bit3 PAR[02...32]_Bit3 | Bit 2 | | | | | |
| | PAR01_Bit4 PAR[02...32]_Bit4 | Bit 3 | | | | | |
| | PAR01_Bit5 PAR[02...32]_Bit5 | Bit 4 | | | | | |
| | PAR01_Bit6 PAR[02...32]_Bit6 | Bit 5 | | | | | |
| | PAR01_Bit7 PAR[02...32]_Bit7 | Bit 6 | | | | | |
| | PAR01_Bit8 PAR[02...32]_Bit8 | Bit 7 | | | | | |
| | 4094 + Index * 8 | PAR01 PAR[02...32] | (U)INT | | | • | |
| | 4092 + Index * 8 | PAR01 PAR[02...32] | (U)DINT | | | • | |

9.28.5.11.7.2 RES data points

Name:

RES[01...32]

RES[01...32]_Bit1

RES[01...32]_Bit2

RES[01...32]_Bit3

RES[01...32]_Bit4

RES[01...32]_Bit5

RES[01...32]_Bit6

RES[01...32]_Bit7

RES[01...32]_Bit8

Once enabled, the RES data points are transported cyclically via X2X Link. They are used to transfer information from the reACTION program to the CPU.

Information:

RES data points DO NOT map the module's input directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | |
|-------------------|-------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 5119 + Index * 8 | RES01 | (U)SINT | • | | | |
| | RES[02...32] | | | | | |
| | RES01_Bit1 | Bit 0 | | | | |
| | RES[02...32]_Bit1 | | | | | |
| | RES01_Bit2 | Bit 1 | | | | |
| | RES[02...32]_Bit2 | | | | | |
| | RES01_Bit3 | Bit 2 | | | | |
| | RES[02...32]_Bit3 | | | | | |
| | RES01_Bit4 | Bit 3 | | | | |
| | RES[02...32]_Bit4 | | | | | |
| | RES01_Bit5 | Bit 4 | | | | |
| | RES[02...32]_Bit5 | | | | | |
| | RES01_Bit6 | Bit 5 | | | | |
| RES[02...32]_Bit6 | | | | | | |
| RES01_Bit7 | Bit 6 | | | | | |
| RES[02...32]_Bit7 | | | | | | |
| RES01_Bit8 | Bit 7 | | | | | |
| RES[02...32]_Bit8 | | | | | | |
| 5118 + Index * 8 | RES01 | (U)INT | • | | | |
| | RES[02...32] | | | | | |
| 5116 + Index * 8 | RES01 | (U)DINT | • | | | |
| | RES[02...32] | | | | | |

9.28.5.11.7.3 PVAR and RVAR data points

Name:

PVAR[1...256]

RVAR[1...256]

In addition to PAR and RES data points, VAR data points can also be defined in the reACTION program. They are a direct component of the reACTION program and can be accessed acyclically by the CPU. Like the PAR and RES data points, the PVAR data points are used to transfer information from the CPU to the reACTION program. The RVAR data points are used to transfer feedback from the reACTION program to the CPU.

| Data type | Value |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

| Register | Name | Data type | Read | | Write | |
|------------------|------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 6140 + Index * 8 | PVAR1 PVAR[2...256] | DINT | | | | • |
| 6140 + Index * 8 | RVAR1 RVAR[2...256] | DINT | | • | | |

9.28.5.11.8 reACTION function blocks - General

The following tables provide an overview of I/O channel assignments to reACTION function blocks.

Digital inputs/outputs

| Channel | Function block | | |
|-----------------|-----------------------|-----------|----------------------|
| | Mapping ¹⁾ | rTiDin | rTiDout, rTiDoutTime |
| X1: DI 1 | 0x00 | Channel 1 | |
| X1: DI 2 | 0x01 | Channel 2 | |
| X1: DI 3 / DO 3 | 0x02 | Channel 3 | Channel 3 |
| X1: DI 4 / DO 4 | 0x03 | Channel 4 | Channel 4 |
| X1: DI 5 | 0x04 | Channel 5 | |
| X1: DI 6 | 0x05 | Channel 6 | |
| X1: DI 7 / DO 7 | 0x06 | Channel 7 | Channel 7 |
| X1: DI 8 / DO 8 | 0x07 | Channel 8 | Channel 8 |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see ["reACTION function blocks - Configuration" on page 3535](#)).

Analog outputs

| Channel | Function block | | |
|----------|-----------------------|--------|-----------|
| | Mapping ¹⁾ | rTiAin | rTiAout |
| X2: AO 1 | 0x00 | | Channel 1 |
| X2: AO 2 | 0x01 | | Channel 2 |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see ["reACTION function blocks - Configuration" on page 3535](#)).

9.28.5.11.9 reACTION function blocks - Configuration

Some function blocks in library AsIoRti must be configured before they can be used.

| Function block | Information |
|----------------|--|
| rtiABRPos | The module offers the option of using function block rtiABRPos once in the reACTION program. To do so, the function block must be assigned 3 digital inputs that are no longer available for rtiDin. |
| rtiABCnt | The module offers the option of using function block rtiABCnt up to 3 times in the reACTION program. To do so, the function blocks must be assigned 2 digital inputs as an A or B track that are no longer available for rtiDin. In addition, an external event can be defined for each rtiABCnt function block. The input used for this is also no longer available for rtiDin. |

Table 608: List of function blocks requiring prior configuration

9.28.5.11.9.1 Function blocks rtiABRPos and rtiABCnt

Function blocks rtiABRPos and rtiABCnt can be used to process the position value of an ABR incremental encoder in a reACTION task. Several hardware channels of the module are used for this. The incoming signals are interpreted by the reACTION engine and converted into a location.

The update rate depends on both the reACTION engine and the hardware used. The reACTION engine is basically able to calculate positions with an update rate of up to 8 MHz. The input frequencies of the hardware inputs can be taken from the technical data of the respective module.

These function blocks can be used separately or in combination.

Using function block rtiABRPos

The following points are important to keep in mind when using function block rtiABRPos in a reACTION program:

- The function block can only be used once in a reACTION program.
- 3 digital inputs must be defined on the module for input signals A, B and R.
- In addition, a digital input of the module can be defined as an event input.

Example diagram of input signals:

Figure 342: Schematic diagram of input signals for rtiABRPos

Using function block rtiABCnt

The following points must be taken into account when using function block rtiABCnt in a reACTION program:

- The function block can be used up to 3 times in a reACTION program.
- 2 digital inputs must be defined on the module for input signals A and B.
- In addition, up to 3 digital inputs on the module can be defined as event inputs E1, E2 and E3.

Example diagram of input signals:

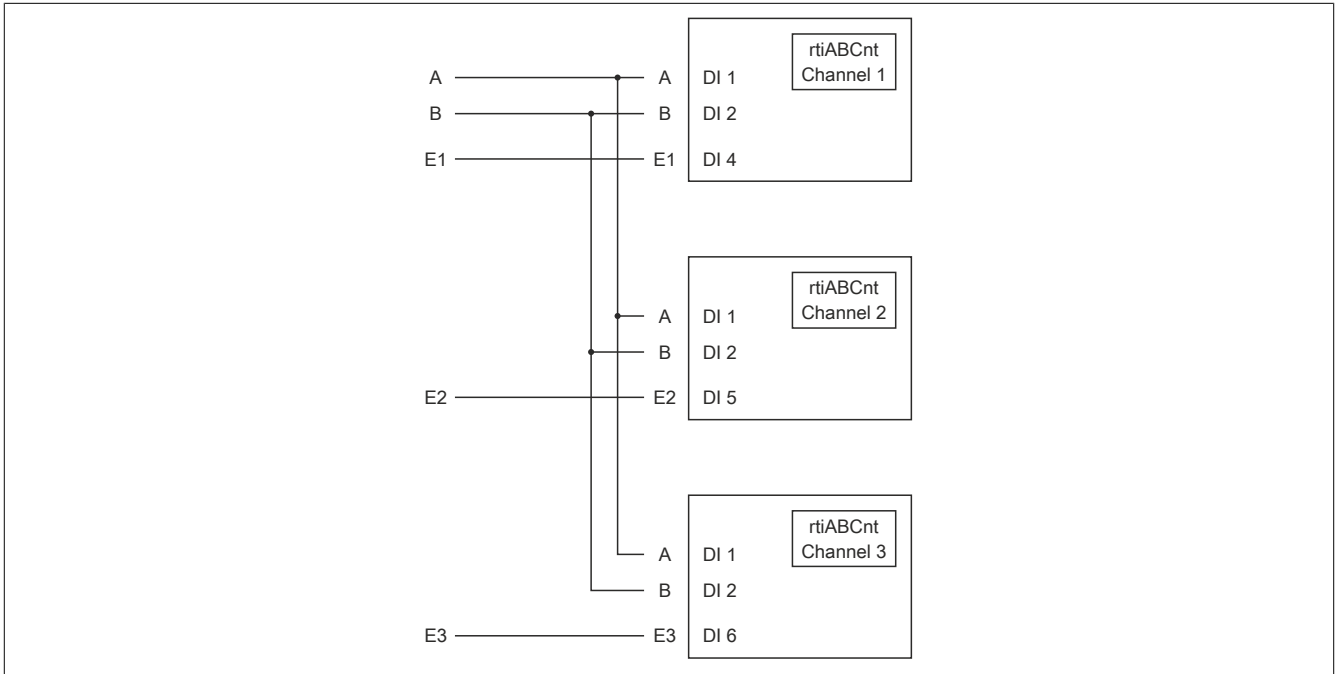

Figure 343: Schematic diagram of input signals for rtiABCnt

Using function blocks rtiABRPos and rtiABCnt in combination

The following points should be kept in mind when using function blocks rtiABRPos and rtiABCnt together in a reACTION program.

- Function block rtiABRPos can only be used once in a reACTION program.
- Function block rtiABCnt can be used up to 2 times in a reACTION program.
- 3 digital inputs must be defined for input signals A, B and R (rtiABRPos).
- The same digital inputs are used for input signals A and B (rtiABCnt).
- In addition, up to 3 event inputs E1, E2 and E3 can be defined (rtiABCnt).
- E1 is used for the event input (rtiABRPos).

Example diagram of input signals:

Figure 344: Diagram of input signals when using rtiABRPos and rtiABCnt at the same time

Registering the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_Config_ABR1

This register specifies the technical characteristics of the connected ABR incremental encoder.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|------------|---|
| 0 - 15 | Increments per revolution | 0 to 65535 | Reference pulse monitoring: If the reference pulse is different than defined here, this is indicated on the status output of function block rtiABRPos. |
| 16 | Inversion of the counting direction set by signals A and B | 0 | Positive counting direction |
| | | 1 | Negative counting direction |
| 17 - 31 | Reserved | 0 | |

Wiring the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_ChannelMapping1_ABR1

CfO_ChannelMapping2_ABR1

Before function blocks rtiABRPos/rtiABCnt can be processed by the reACTION engine, the hardware inputs to be used by the ABR incremental encoder must be defined on the module. The "ChannelMapping" registers specify which inputs are interpreted as the A, B, R, E1, E2 and E3 signals.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure of CfO_ChannelMapping1_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---------------------------------------|
| 0 - 7 | Input E1 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 8 - 15 | Input R | 0 to 255 | For possible values, see bits 0 to 7. |
| 16 - 23 | Input B | 0 to 255 | For possible values, see bits 0 to 7. |
| 24 - 31 | Input A | 0 to 255 | For possible values, see bits 0 to 7. |

Bit structure of CfO_ChannelMapping2_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---|
| 0 - 15 | Reserved | 0 | |
| 16 - 23 | Input E3 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 24 - 31 | Input E2 | 0 to 255 | For possible values, see bits 16 to 23. |

Information:

For information about the relationship between the input on the module and the channel name, see section "reACTION function blocks - General".

Scaling the position encoder (rtiABRPos)

Name:

CfO_ScalingUnits_ABR1

CfO_ScalingIncrements_ABR1

An optional gear ratio can be configured using registers "Units" and "Increments". The dividend for scaling is defined in register "Units"; the divisor is defined in register "Increments".

| Data type | Value | Information |
|-----------|--------------------|--|
| UDINT | 0 to 4,294,967,295 | CfO_ScalingUnits_ABR1: Units per interval CfO_ScalingIncrements_ABR1: Increments per interval |

Formula for calculation

$$\text{Gear ratio} = \text{ScalingUnits} / \text{ScalingIncrements}$$
Example 1

ScalingUnits = 1

ScalingIncrements = 1

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 1/1$$

In this example, the ABR position value is output unchanged on output "Pos".

Example 2

ScalingUnits = 10

ScalingIncrements = 4

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 10/4$$

In this example, the ABR position value is multiplied by 2.5 and output on output "Pos".

Information:

The encoder values are calculated internally as INT64 values in 32.32 format. On output "Pos" of function block "rtiABRPos", only the whole number value (INT32) is output for the user. The fixed point decimal places are used internally to calculate a higher resolution.

9.28.5.11.10 Direct I/O configuration

This module is equipped with 8 digital channels and 2 analog outputs. In the "Direct I/O" function model, behavior is based on that of a standard module. The I/O channels are managed by an extremely simplified reACTION program. The function model primarily serves to check that the I/O channels are functioning properly.

9.28.5.11.10.1 Direction of digital channels

Name:

CfO_DigitalDirection

This register determines the signal direction of digital channels 3, 4, 7 and 8.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-------------------------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | Direction - Digital channel 3 | 0 | Input |
| | | 1 | Output |
| 3 | Direction - Digital channel 4 | 0 | Input |
| | | 1 | Output |
| 4 - 5 | Reserved | 0 | |
| 6 | Direction - Digital channel 7 | 0 | Input |
| | | 1 | Output |
| 7 | Direction - Digital channel 8 | 0 | Input |
| | | 1 | Output |

9.28.5.11.10.2 Filtering digital channels

Name:

CfO_DigitalFilter

This register defines the filter time of the digital channels. The filter value affects both the switching delay as well as the immunity of the channels.

| Data type | Value |
|-----------|--------------------------|
| UDINT | 0 to 500000: Units 10 ns |

9.28.5.11.11 Direct I/O communication

This module is equipped with the following inputs and outputs:

- 4 digital inputs (sink) for 24 VDC
- 4 digital channels configurable as inputs (sink) or outputs (sink or source) for 24 VDC
- 2 analog outputs of type ± 10 V

9.28.5.11.11.1 Digital outputs

Name:

DigitalOutput03

DigitalOutput04

DigitalOutput07

DigitalOutput08

This register is used to predefine the value that should be output on the digital output.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | DigitalOutput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalOutput04 | 0 | FALSE |
| | | 1 | TRUE |
| 4 - 5 | Reserved | 0 | |
| 6 | DigitalOutput07 | 0 | FALSE |
| | | 1 | TRUE |
| 7 | DigitalOutput08 | 0 | FALSE |
| | | 1 | TRUE |

9.28.5.11.11.2 Digital inputs

Name:

DigitalInput01

DigitalInput02

DigitalInput03

DigitalInput04

DigitalInput05

DigitalInput06

DigitalInput07

DigitalInput08

This register indicates the value read for the respective digital input.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------|-------|-------------|
| 0 | DigitalInput01 | 0 | FALSE |
| | | 1 | TRUE |
| 1 | DigitalInput02 | 0 | FALSE |
| | | 1 | TRUE |
| 2 | DigitalInput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalInput04 | 0 | FALSE |
| | | 1 | TRUE |
| 4 | DigitalInput05 | 0 | FALSE |
| | | 1 | TRUE |
| 5 | DigitalInput06 | 0 | FALSE |
| | | 1 | TRUE |
| 6 | DigitalInput07 | 0 | FALSE |
| | | 1 | TRUE |
| 7 | DigitalInput08 | 0 | FALSE |
| | | 1 | TRUE |

9.28.5.11.11.3 Analog outputs

Name:

AnalogOutput01

AnalogOutput02

This register is used to specify the value for the respective analog output.

| Data type | Value |
|-----------|-----------------|
| INT | -32767 to 32767 |

9.28.5.11.12 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.28.5.11.13 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 200 μ s |

9.28.6 X20RT8381

Data sheet version: 1.02

9.28.6.1 General information

This reACTION Technology module is equipped with 4 high-speed digital inputs and 4 high-speed digital mixed channels. All connections are designed for 1-wire connections. All inputs are designed for sink connections; the outputs are designed for push-pull connections.

A voltage signal of ± 10 V can be read or output using 2 analog inputs and 1 analog output, respectively.

Ultrafast reACTION Technology makes it possible to control the integrated I/O channels with response times down to 1 μ s. All of the commands that can be used for reACTION programs are provided as function blocks in special libraries (e.g. AsIORTI). Programming in compliance with IEC 61131-3 requirements takes place in the Function Block Diagram editor in Automation Studio.

The module supports blackout mode. In blackout mode, programmable module functionality persists even if the network fails.

- reACTION Technology module
- 4 high-speed digital inputs
- 4 high-speed digital channels, configurable as inputs or outputs
- 2 high-speed analog inputs ± 10 V
- 1 high-speed analog output ± 10 V
- 1 ABR incremental encoder input 24 V
- Pulse width modulation
- Support of data type "REAL" for arithmetic operations
- Supports blackout mode

9.28.6.2 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | reACTION Technology modules |  |
| X20RT8381 | X20 reACTION module, real computing function, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, 2 analog inputs ± 10 V, 500 kHz sampling frequency, 13-bit converter resolution including sign, configurable input filter, 1 analog output ± 10 V, 2 μ s, 13-bit converter resolution including sign, reACTION Technology module | |

| Bus | 0.01 W |
| Internal I/O | 1.7 W |
| Additional power dissipation caused by actuators (resistive) [W] | +1.1 |
| Type of signal lines ¹⁾ | Shielded cables must be used for all signal lines, cable length: Max. 20 m |
| Application memory | |
| Type | 64 Mbit flash memory |
| Data retention | 20 years at 55°C |
| Guaranteed erase/write cycles | 100,000 |
| Certifications | |
| CE | Yes |
| EAC | Yes |
| UL | cULus E115267 Industrial control equipment |
| Digital inputs | |
| Quantity | 4 inputs and 4 mixed channels, configurable as inputs or outputs using software |
| Nominal voltage | 24 VDC |
| Input voltage | 24 VDC -15% / +20% |
| Input current at 24 VDC | Typ. 1.3 mA |
| Input circuit | Sink |
| Input filter | |
| Hardware | <3 μ s |
| Software | Default 200 ns, configurable between 200 ns and 5 ms in 10 ns intervals |
| Connection type | 1-wire connections |
| Input resistance | 18.16 k Ω |
| Switching threshold | |
| Low | <5 VDC |
| High | >15 VDC |
| Isolation voltage between channel and bus | 500 V _{eff} |
| ABR incremental encoder | |
| Quantity | 2 |
| Encoder inputs | 24 V, asymmetrical |
| Counter size | 32-bit |
| Input frequency | Max. 333 kHz |
| Evaluation | 4x |
| Analog inputs | |
| Quantity | 2 ²⁾ |
| Input | ± 10 V |
| Input type | Differential input |
| Digital converter resolution | ± 12 -bit |
| Output format | |
| Data type | INT |
| Voltage | INT 0x8001 - 0x7FFF / 1 LSB = 0x0008 = 2.441 mV |
| Input impedance in signal range | 20 M Ω |
| Input protection | Protection against wiring with supply voltage |
| Permissible input signal | Max. ± 30 V |
| Output of digital value during overload | |
| Undershoot | 0x8001 |
| Overshoot | 0x7FFF |
| Conversion procedure | SAR |
| Input filter | 3rd-order low pass / cutoff frequency 130 kHz |
| Max. error at 25°C | |
| Gain | 0.08% ³⁾ |
| Offset | 0.018% ⁴⁾ |

Table 610: X20RT8381 - Technical data

| Model number | X20RT8381 |
|---|--|
| Max. gain drift | 0.003 %/°C ³⁾ |
| Max. offset drift | 0.001 %/°C ⁴⁾ |
| Common-mode rejection | |
| DC | 86 dB |
| 50 Hz | 84 dB |
| Common-mode range | ±12 V |
| Nonlinearity | 0.015% ⁴⁾ |
| Isolation voltage between channel and bus | 500 V _{eff} |
| Sampling frequency | 500 kHz |
| Digital outputs | |
| Quantity ⁵⁾ | 4 mixed channels, configurable as inputs or outputs using software |
| Variant | Push-Pull |
| Nominal voltage | 24 VDC |
| Switching voltage | 24 VDC -15% / +20% |
| Nominal output current | 100 mA |
| Total nominal current | 400 mA |
| Connection type | 1-wire connections |
| Output circuit | Sink or source |
| Output protection | Thermal cutoff if overcurrent or short circuit occurs (see value "Peak short circuit current") |
| Diagnostic status | Output monitoring with delay <700 ns |
| Leakage current when switched off | Approx. 25 µA |
| R _{DS(on)} | 140 mΩ |
| Residual voltage | <0.4 V at nominal current 100 mA |
| Max. continuous current | 100 mA |
| Peak short-circuit current | <10 A |
| Switch-on in the event of overload shutdown or short-circuit shutdown | Approx. 3 ms |
| Switching delay | |
| 0 → 1 | <1 µs |
| 1 → 0 | <1 µs |
| Switching frequency | |
| Resistive load | Min. 50 kHz, max. 500 kHz |
| Isolation voltage between channel and bus | 500 V _{eff} |
| Analog outputs | |
| Quantity | 1 |
| Output | ±10 V |
| Digital converter resolution | ±12-bit |
| Conversion time | 2 µs |
| Settling time for output changes over entire range | 5 µs |
| Switch on/off behavior | Internal enable relay for startup |
| Max. error at 25°C | |
| Gain | 0.15% ⁶⁾ |
| Offset | 0.05% ⁷⁾ |
| Output protection | Short circuit protection |
| Output format | |
| Data type | INT |
| Voltage | INT 0x8000 - 0x7FFF / 1 LSB = 0x0008 = 2.441 mV |
| Load per channel | Max. ±10 mA, load ≥1 kΩ |
| Short-circuit proof | Current limiting ±65 mA |
| Output filter | 1st-order low pass / cutoff frequency 22 kHz |
| Max. gain drift | 0.022 %/°C ⁶⁾ |
| Max. offset drift | 0.032 %/°C ⁷⁾ |
| Error caused by load change | Max. 0.14%, from 10 MΩ → 1 kΩ, resistive |
| Nonlinearity | 0.005% ⁸⁾ |
| Isolation voltage between channel and bus | 500 V _{eff} |
| Electrical properties | |
| Electrical isolation | Channel isolated from bus Channel not isolated from channel |
| Operating conditions | |
| Mounting orientation | |
| Horizontal | Yes |
| Vertical | Yes |
| Installation elevation above sea level | |
| 0 to 2000 m | No limitation |
| >2000 m | Reduction of ambient temperature by 0.5°C per 100 m |
| Degree of protection per EN 60529 | IP20 |

Table 610: X20RT8381 - Technical data

| Model number | X20RT8381 |
|---------------------------------|--|
| Ambient conditions | |
| Temperature | |
| Operation | |
| Horizontal mounting orientation | -25 to 60°C |
| Vertical mounting orientation | -25 to 50°C |
| Derating | See section "Derating and hardware configuration" |
| Storage | -40 to 85°C |
| Transport | -40 to 85°C |
| Relative humidity | |
| Operation | 5 to 95%, non-condensing |
| Storage | 5 to 95%, non-condensing |
| Transport | 5 to 95%, non-condensing |

Table 610: X20RT8381 - Technical data

- 1) See section "X20 shielding brackets".
- 2) To reduce power dissipation, B&R recommends bridging unused inputs on the terminal.
- 3) Based on the current measured value.
- 4) Based on the 20 V measurement range.
- 5) See section "Derating and hardware configuration".
- 6) Based on the current output value.
- 7) Based on the entire output range.
- 8) Based on the output range.

9.28.6.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|--------------------------------|---|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode or blackout mode |
| | | | Double flash | Mode BOOT (during firmware update) ¹⁾ |
| | | | Blinking | Mode PREOPERATIONAL |
| | | | On | Mode RUN |
| | e | Red | Off | Module not supplied with power or everything OK |
| | | | Single flash | Warning/Error on an I/O channel. Level monitoring of digital outputs has been triggered. |
| | | | Double flash | Supply voltage not in valid range or no reACTION program loaded |
| | | | Triple flash | Test of internal memory failed (limited functionality, module must be replaced) |
| | e + r | Solid red / Single green flash | Off | Error or reset state (reACTION program using functions or channels that are not permitted on this hardware) |
| | | | Single flash | Invalid firmware |
| | | | Double flash | Invalid firmware |
| | | | Triple flash | Invalid firmware |
| 1, 2, 5, 6 | Green | | Input state of the corresponding digital input | |
| 3, 4, 7, 8 | Green | | Input or output status of the corresponding digital input or output | |

Table 611: LED status indicators (X1)

1) A firmware update can take several minutes depending on the configuration.

| Figure | LED | Color | Status | Description |
|--|-------|--------|----------|--|
|  | 1 - 2 | Green | Off | Open circuit or disconnected sensor |
| | | | Blinking | Input signal overflow or underflow |
| | | | On | Analog/Digital converter running, value OK |
| | 1 | Orange | Off | Value = 0 |
| | | | Blinking | Value = 0 |
| | | | On | Value ≠ 0 |

Table 612: LED status indicators (X2)

9.28.6.5 Pinout

9.28.6.5.1 X1 - Pinout

To prevent crosstalk, each individual signal line should be shielded. The maximum cable length is 20 m.

Figure 345: X1 - Pinout

9.28.6.5.2 X2 - Pinout

To prevent crosstalk, each individual signal line should be shielded. The maximum cable length is 20 m.

Figure 346: X2 - Pinout

9.28.6.6 Local I/O channels

The following tables provide an overview of the connections to the I/O channels.

Digital inputs/outputs

| Connection | Terminal connection | Channel |
|------------|---------------------|-------------|
| X1 | 11 | DI 1 |
| | 21 | DI 2 |
| | 12 | DI 3 / DO 3 |
| | 22 | DI 4 / DO 4 |
| | 13 | DI 5 |
| | 23 | DI 6 |
| | 14 | DI 7 / DO 7 |
| | 24 | DI 8 / DO 8 |

Analog inputs

| Connection | Terminal connection | Channel |
|------------|---------------------|---------|
| X2 | 11 and 12 | AI 1 |
| | 21 and 22 | AI 2 |

Analog output

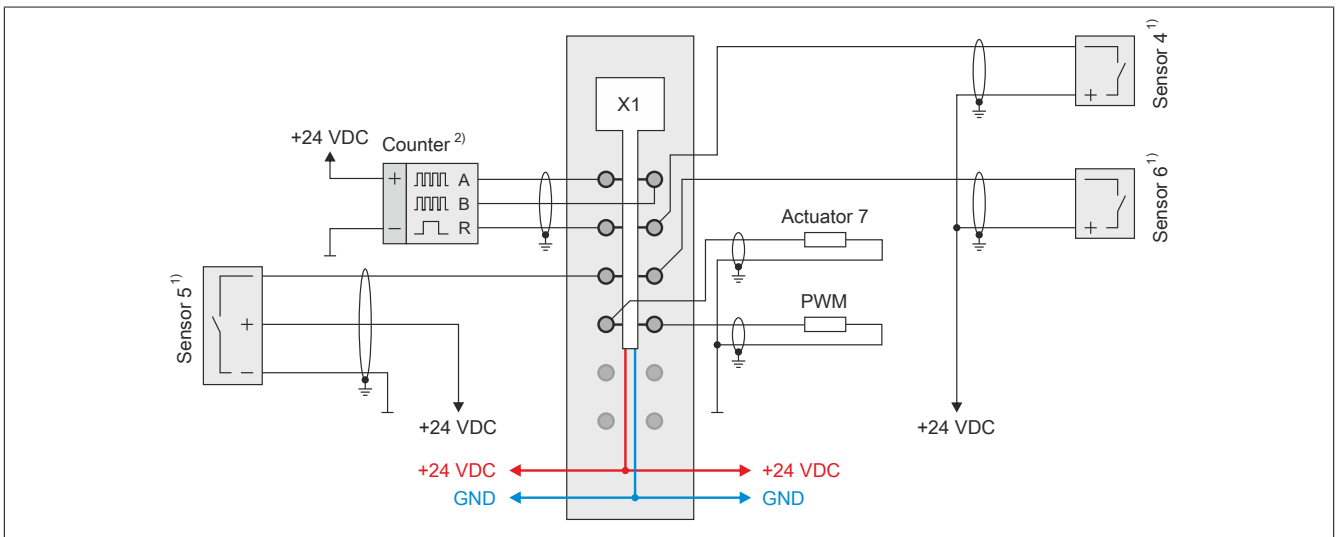

| Connection | Terminal connection | Channel |
|------------|---------------------|---------|
| X2 | 13 and 14 | AO 1 |

The following sections describe assigning I/O channels in a reACTION program:

| I/O channels | Assignment |
|-----------------------|--|
| Digital I/O channels | Assignment of digital inputs/outputs |
| Analog input channels | Assignment of analog inputs |
| Analog output channel | Assignment of analog output |

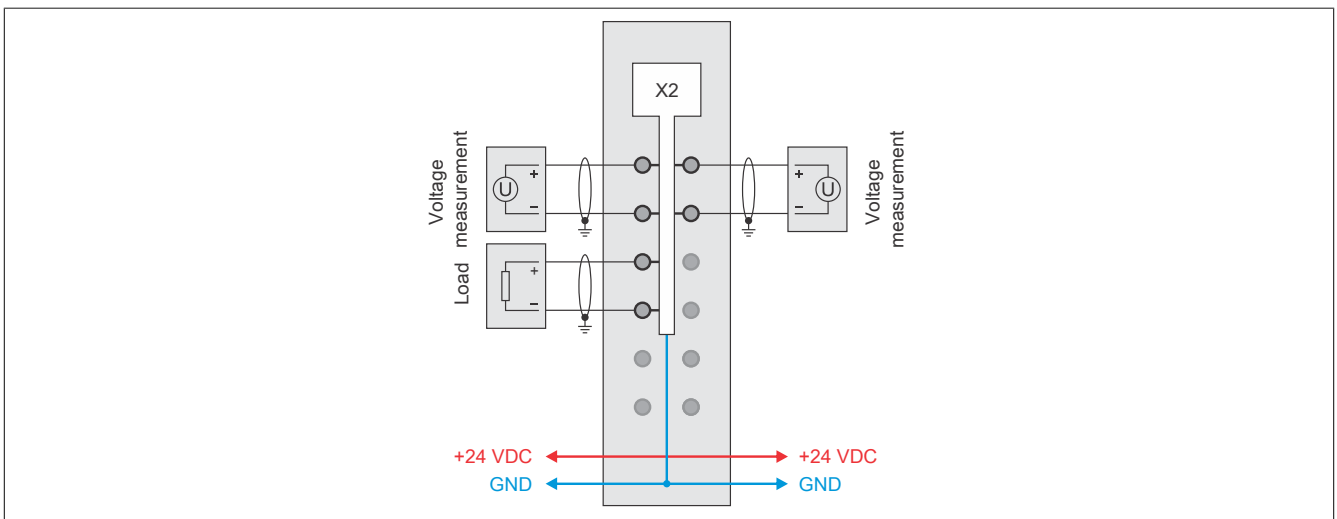

9.28.6.7 Connection examples

9.28.6.7.1 X1 - Connection example

- 1) Observe the cabling guidelines from the sensor manufacturer.
- 2) Observe the cabling guidelines from the encoder manufacturer.

Figure 350: Output circuit diagram of the analog output (X2)

9.28.6.9 Derating and hardware configuration

To ensure proper operation, observe the points listed below:

- Number of operable digital outputs
- Hardware configurations

9.28.6.9.1 Number of operable digital outputs

Depending on the mounting orientation, not all 4 digital outputs of the module can be operated starting at a certain ambient temperature.

Information:

To ensure operation of the module with the ambient temperatures listed below, it is absolutely necessary to disconnect channels.

Reducing the output current per channel does not increase the number of digital output channels that can be operated in the corresponding ambient temperature class.

Horizontal installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <45°C | 4 |
| Starting at 45°C | 3 |
| Starting at 55°C | 2 |

Vertical installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <35°C | 4 |
| Starting at 35°C | 3 |
| Starting at 45°C | 2 |

9.28.6.9.2 Hardware configuration for horizontal installation

9.28.6.9.2.1 Hardware configuration starting at an ambient temperature of 50°C

Operating a reACTION module

Starting at an ambient temperature of 50°C, a dummy module must be connected to the left of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.6.9.2.2 Hardware configuration starting at an ambient temperature of 55°C

Operating a reACTION module

Starting at an ambient temperature of 55°C, a dummy module must be connected to the left and right of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

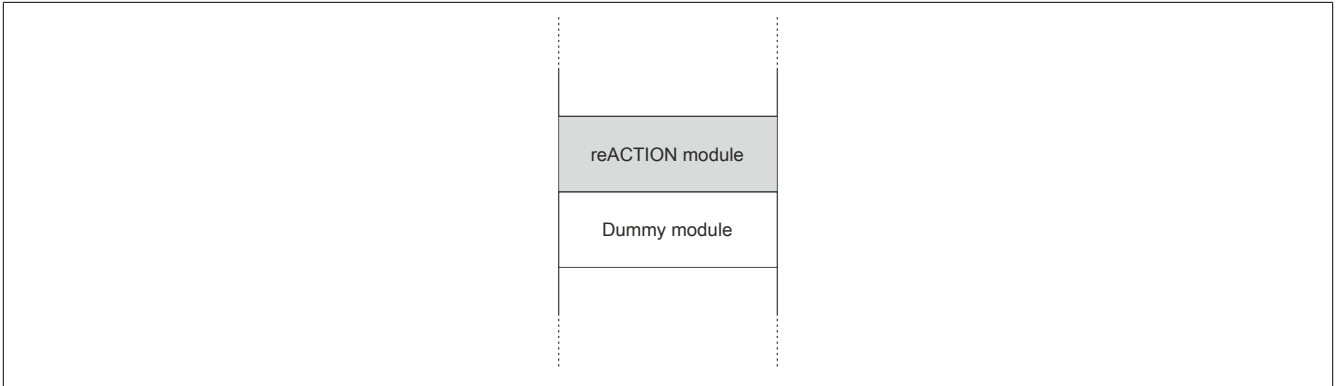

9.28.6.9.3 Hardware configuration for vertical installation

9.28.6.9.3.1 Hardware configuration starting at an ambient temperature of 40°C

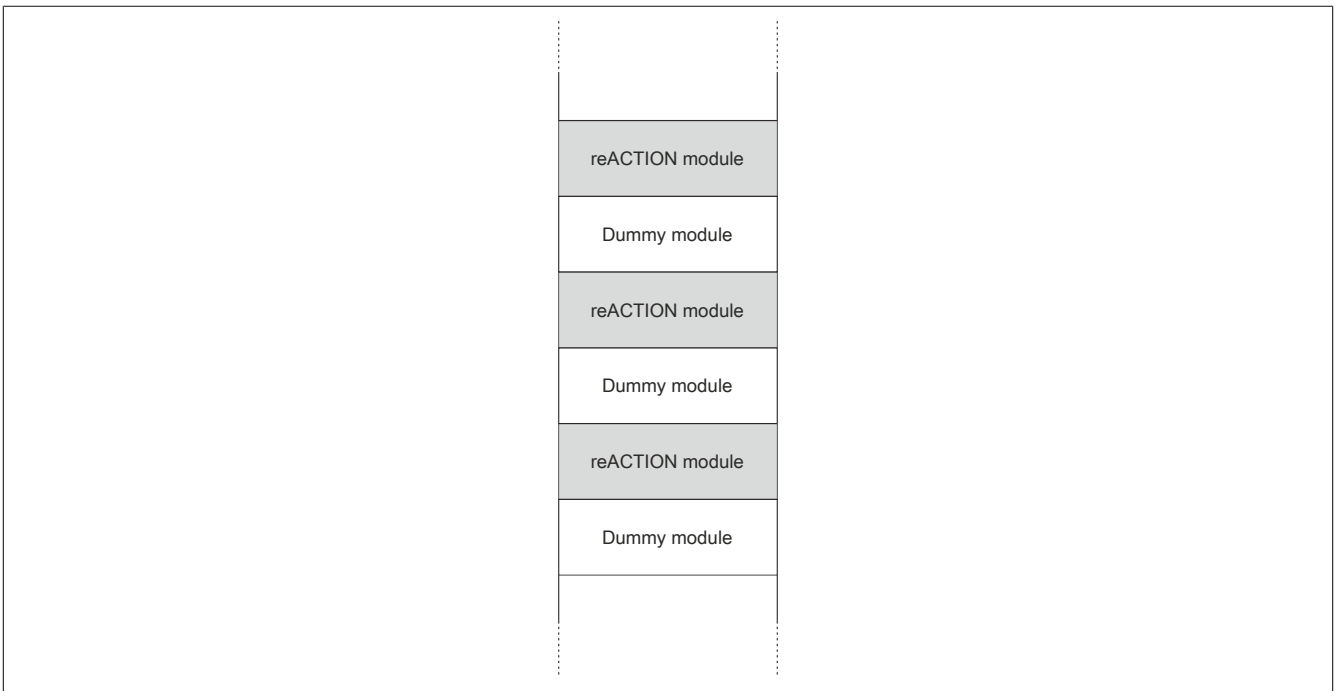

Operating a reACTION module

At ambient temperatures starting at 40°C, a dummy module must be installed below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

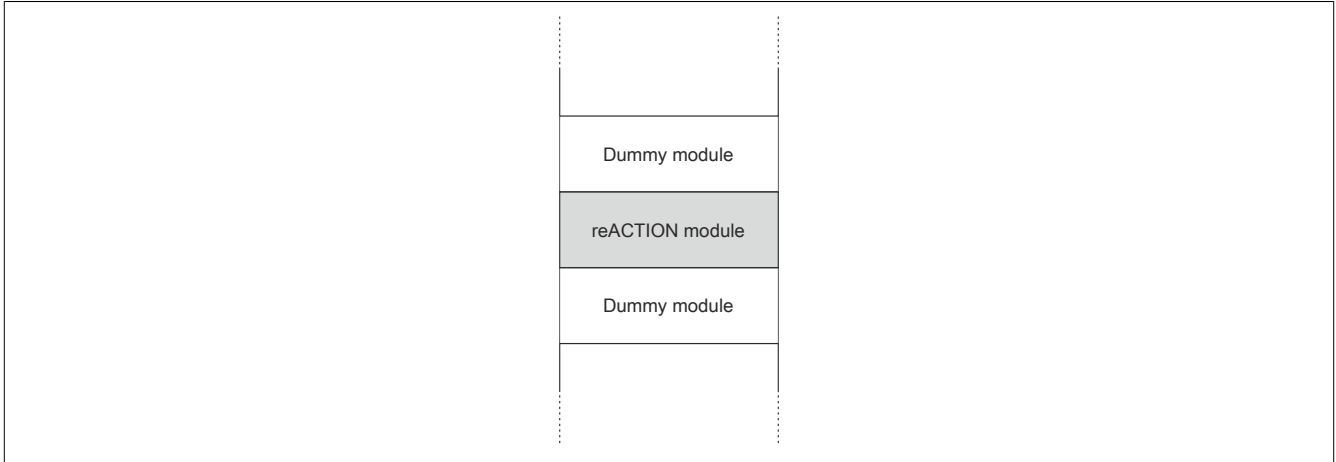

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.6.9.3.2 Hardware configuration starting at an ambient temperature of 45°C

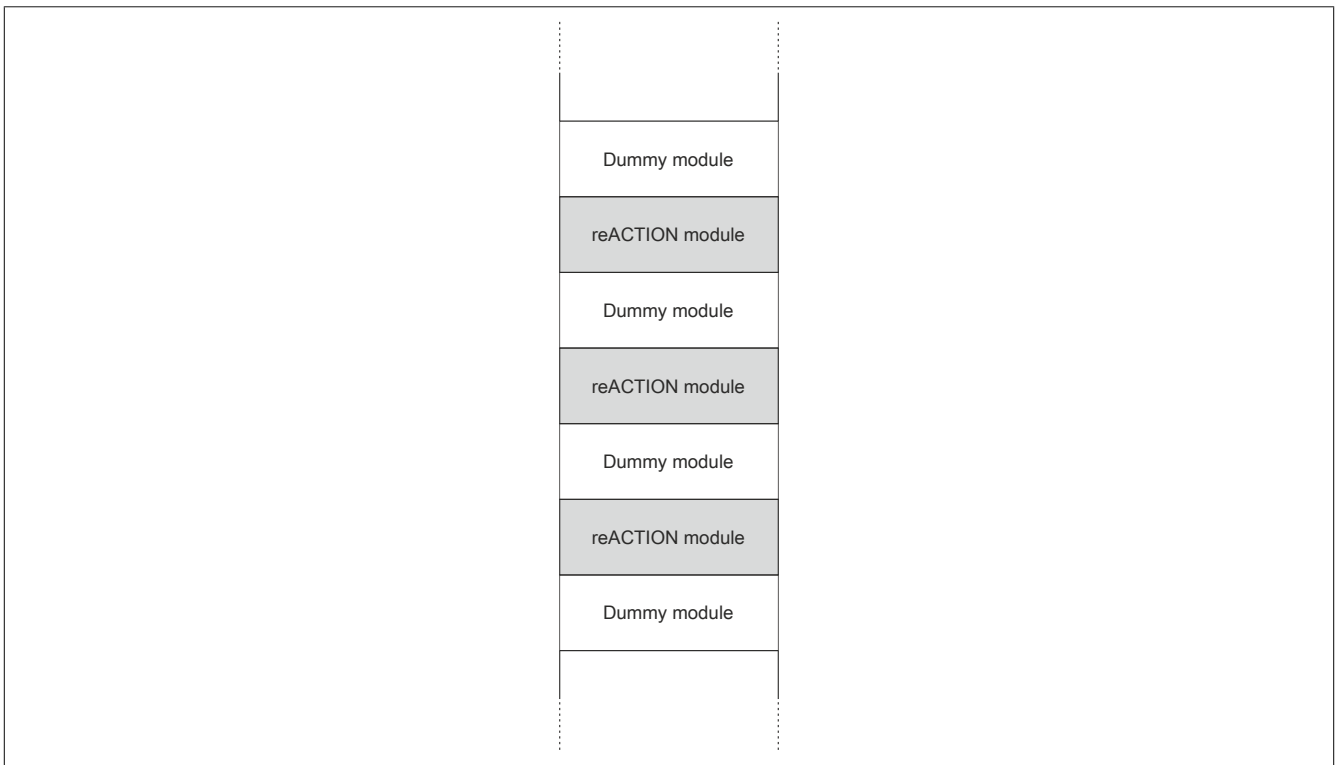

Operating a reACTION module

At ambient temperatures starting at 45°C, dummy modules must be installed above and below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.6.10 Enabling blackout mode

The following steps must be carried out to enable blackout mode.

Requirements

- reACTION program transferred to reACTION module
- Reset triggered on reACTION module:
This ensures that the program stored in the reACTION memory will be loaded with every subsequent reset.

Enabling

- Set the enable register for blackout mode.
- Control bit "RTEnable" must be set. This bit starts the reACTION engine.

Activation

- A connection error triggers a reset on the reACTION module.
- PAR and VAR data points are set to 0.
- Blackout mode is enabled on the reACTION module.

9.28.6.10.1 Blackout mode

For a description of blackout mode, see ["Blackout mode" on page 3794](#).

9.28.6.11 Register description

9.28.6.11.1 System requirements

The following minimum versions are recommended to generally be able to use all functions:

- Automation Studio 4.4.3
- Automation Runtime 4.08

9.28.6.11.2 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.28.6.11.3 Function model 0 - "reACTION"

When using function model "reACTION", a reACTION program must be created specifically for the module. Later, this program will be executed by the reACTION module, not by the CPU. This allows certain machine tasks to be managed decentrally and with a very short response time.

The inputs and outputs of a reACTION module can only be operated by an enabled reACTION program. Interaction registers allow information to be exchanged between the CPU and the reACTION program on the module.

In addition to communication with the CPU, the cyclic interaction registers can also be used for "cross-mapping". In this way, inputs/outputs can also be read/controlled by external modules across the entire X2X Link or POWERLINK network.

| Register | Name | Data type | Read | | Write | |
|---------------------------------|--------------------------------|------------------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module communication | | | | | | |
| 158 | ModuleStatus | UINT | | • | | |

9.28.6.11.4 Function model 254 - "Direct I/O"

In function model "Direct I/O", a special reACTION program is executed in the module in order to manage the I/O channels. In addition, cyclic registers are used to exchange information with the CPU. This simulates the behavior of a standard module.

| Register | Name | Data type | Read | | Write | |
|-----------------------------------|---------------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module communication | | | | | | |
| 129 | Status - Acknowledgment | USINT | | | • | |
| | RTHardwareWarningQuit | Bit 2 | | | | |

9.28.6.11.5 Module communication

9.28.6.11.5.1 Module status messages

Name:

ModuleStatus

This register is used to transfer general status messages for the module.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|--------------------------------------|---------------------|-------|---|
| Status word - Module (L byte) | | | |
| 0 | Reserved | - | |
| 1 | InternalSupplyOk_X1 | 0 | Internal voltage conversion for X1 faulty |
| | | 1 | No error |
| 2 | SensorSupplyOk_X2 | 0 | Power supply for X2 faulty |
| | | 1 | No error |
| 3 | InternalSupplyOk_X2 | 0 | Internal voltage conversion for X2 faulty |
| | | 1 | No error |
| 4 - 5 | Reserved | - | |
| 6 | X1ToX2ComError | 0 | No error |
| | | 1 | X1 → X2 communication faulty |
| 7 | X2ToX1ComError | 0 | No error |
| | | 1 | X2 → X1 communication faulty |
| Status word - Module (H byte) | | | |
| 0 | AnalogIn01ComError | 0 | No error |
| | | 1 | Value from analog input 1 faulty |
| 1 | AnalogIn02ComError | 0 | No error |
| | | 1 | Value from analog input 2 faulty |
| 2 - 3 | Reserved | - | |
| 4 | AnalogOut01ComError | 0 | No error |
| | | 1 | Value from analog output 1 faulty |
| 5 - 7 | Reserved | - | |

9.28.6.11.5.2 Status messages for the digital channels

Name:

DigitalStatus

This register is used to transfer general status messages for the digital channels.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|---------------------------------------|------------------------|-------|---|
| Status word - Digital (L byte) | | | |
| 0 - 1 | Reserved | - | |
| 2 | DigitalOutput3Overload | 0 | Digital output 3 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 3 | DigitalOutput4Overload | 0 | Digital output 4 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 4 - 5 | Reserved | - | |
| 6 | DigitalOutput7Overload | 0 | Digital output 7 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 7 | DigitalOutput8Overload | 0 | Digital output 8 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |

9.28.6.11.5.3 Status messages from analog inputs

Name:

AnalogInputStatus

This register transfers general status messages of analog inputs.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|--|---------------------|-------|--|
| Status word - AnalogIn (L byte) | | | |
| 0 | AnalogIn01Underflow | 0 | No error |
| | | 1 | Lower limit value from analog input 1 underrun |
| 1 | AnalogIn01Overflow | 0 | No error |
| | | 1 | Upper limit value from analog input 1 exceeded |
| 2 | AnalogIn01OpenLoop | 0 | No error |
| | | 1 | Open circuit determined on analog input 1 |
| 3 - 7 | Reserved | - | |
| Status word - AnalogIn (H byte) | | | |
| 0 | AnalogIn02Underflow | 0 | No error |
| | | 1 | Lower limit value from analog input 2 underrun |
| 1 | AnalogIn02Overflow | 0 | No error |
| | | 1 | Upper limit value from analog input 2 exceeded |
| 2 | AnalogIn02OpenLoop | 0 | No error |

9.28.6.11.6 reACTION - Configuration

9.28.6.11.6.1 reACTION cycle time

Name:

ReActionCycleTimeValue

ReActionCycleTimeMultiplier

Registers "TimeValue" and "Multiplier" predefine the desired cycle time for the reACTION program. Register "TimeValue" contains the value, while register "Multiplier" contains the associated units.

Register "Multiplier" is currently permanently set to 1000 in order to predefine the cycle time with μ s precision.

| Data type | Value |
|-----------|------------|
| UDINT | 1 to 10000 |

9.28.6.11.6.2 Configuring PAR data points

Name:

CfO_PARType01

CfO_PARType[02...04]

PAR data points can be defined for the reACTION program. To enable them, the desired data type must be made known according to the configuration in Automation Studio.

| Data type | Value |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|---------|-----------------|-------|-------------|
| 0 - 3 | Type01 - PAR 1 | 0000 | Inactive |
| | Type02 - PAR 9 | 0001 | USINT, BOOL |
| | Type03 - PAR 17 | | |
| | Type04 - PAR 25 | | |
| 4 - 7 | Type01 - PAR 2 | 0010 | UINT |
| | Type02 - PAR 10 | 0011 | UDINT, REAL |
| | Type03 - PAR 18 | | |
| | Type04 - PAR 26 | | |
| 8 - 11 | Type01 - PAR 3 | 0100 | Reserved |
| | Type02 - PAR 11 | 0101 | SINT |
| | Type03 - PAR 19 | | |
| | Type04 - PAR 27 | | |
| 12 - 15 | Type01 - PAR 4 | 0110 | INT |
| | Type02 - PAR 12 | 0111 | DINT |
| | Type03 - PAR 20 | | |
| | Type04 - PAR 28 | | |
| 16 - 19 | Type01 - PAR 5 | 1000 | Reserved |
| | Type02 - PAR 13 | ... | |
| | Type03 - PAR 21 | 1111 | |
| | Type04 - PAR 29 | | |
| 20 - 23 | Type01 - PAR 6 | | |
| | Type02 - PAR 14 | | |
| | Type03 - PAR 22 | | |
| | Type04 - PAR 30 | | |
| 24 - 27 | Type01 - PAR 7 | | |
| | Type02 - PAR 15 | | |
| | Type03 - PAR 23 | | |
| | Type04 - PAR 31 | | |
| 28 - 31 | Type01 - PAR 8 | | |
| | Type02 - PAR 16 | | |
| | Type03 - PAR 24 | | |
| | Type04 - PAR 32 | | |

9.28.6.11.7 reACTION - Communication

At runtime, the reACTION module program is controlled via the program sequence in the CPU. In its active state, the reACTION program is then executed independently of the program sequence in the CPU.

9.28.6.11.7.1 Controlling the reACTION module

Name:

RTEnable

RTHardwareWarningQuit

This register controls the reACTION program.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------------|-------|--|
| 0 | RTEnable | 0 | Stops the reACTION program |
| | | 1 | Starts the reACTION program |
| 1 | Reserved | - | |
| 2 | RTHardwareWarningQuit | 0 | No effect |
| | | 1 | Acknowledges warning messages for the inputs and outputs |
| 3 - 7 | Reserved | - | |

9.28.6.11.7.2 reACTION module status messages

Name:

RTEngineRun

RTCycleTimeOverrun

RTHardwareWarning

RTFileInvalid

RTFunctionInvalid

RTInstanceInvalid

RTFileNotLoaded

This register is used to output various status messages.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|---|-------|--|
| 0 | RTEngineRun | 0 | reACTION program inactive |
| | | 1 | reACTION program active |
| 1 | RTCycleTimeOverrun | 0 | Configured RT cycle time observed |
| | | 1 | RT cycle time set too short |
| 2 | RTHardwareWarning (group bit for acyclic status data points) | 0 | No status messages |
| | | 1 | Warning message for the inputs and outputs |
| 3 | Reserved | - | |
| 4 | RTFileInvalid (invalid RT program preloaded) | 0 | RT program in RAM OK |
| | | 1 | RT program in RAM invalid |
| 5 | RTFunctionInvalid (invalid software function) | 0 | RT program OK |
| | | 1 | RT program requesting invalid function block |
| 6 | RTInstanceInvalid (invalid hardware instance) | 0 | RT program OK |
| | | 1 | RT program requesting invalid I/O |
| 7 | RTFileNotLoaded | 0 | Valid RT program in RT engine |
| | | 1 | No RT program loaded |

9.28.6.11.7.3 Cycle counter for the active reACTION program

Name:

RTCycleCounter

Register "CycleCounter" can be used to determine how often the reACTION program has cycled.

| Data type | Value |
|-----------|------------|
| UINT | 0 to 65535 |

9.28.6.11.7.4 Minimum cycle time of the active reACTION program

Name:

RTCycleTime

Register "RTCycleTime" can be used to determine how much time the reACTION module needs to cycle through the loaded program once.

| Data type | Value |
|-----------|-------------------------|
| UINT | 0 to 65535: Units 10 ns |

9.28.6.11.8 reACTION - Interaction

After startup, the reACTION program in the module runs independently. It reads the images of the required inputs and manages its assigned outputs throughout the entire network. In addition, the reACTION program can interact with the CPU. There are 3 different data point types available for this.

9.28.6.11.8.1 PAR data points

Name:

PAR[01...32]

PAR[01...32]_Bit1

PAR[01...32]_Bit2

PAR[01...32]_Bit3

PAR[01...32]_Bit4

PAR[01...32]_Bit5

PAR[01...32]_Bit6

PAR[01...32]_Bit7

PAR[01...32]_Bit8

Once enabled, the PAR data points are transported cyclically via X2X Link. They are used to transfer information from the CPU to the reACTION program. They can be used to intervene in the execution of the reACTION program.

Information:

PAR data points DO NOT control the module's outputs directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | |
|------------------|---------------------------------|-----------------------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 4095 + Index * 8 | PAR01 PAR[02...32] | (U)SINT | | | • | |
| | PAR01_Bit1 PAR[02...32]_Bit1 | Bit 0 | | | | |
| | PAR01_Bit2 PAR[02...32]_Bit2 | Bit 1 | | | | |
| | PAR01_Bit3 PAR[02...32]_Bit3 | Bit 2 | | | | |
| | PAR01_Bit4 PAR[02...32]_Bit4 | Bit 3 | | | | |
| | PAR01_Bit5 PAR[02...32]_Bit5 | Bit 4 | | | | |
| | PAR01_Bit6 PAR[02...32]_Bit6 | Bit 5 | | | | |
| | PAR01_Bit7 PAR[02...32]_Bit7 | Bit 6 | | | | |
| | PAR01_Bit8 PAR[02...32]_Bit8 | Bit 7 | | | | |
| | 4094 + Index * 8 | PAR01 PAR[02...32] | (U)INT | | | • |
| 4092 + Index * 8 | PAR01 PAR[02...32] | (U)DINT, REAL | | | • | |

9.28.6.11.8.2 RES data points

Name:

RES[01...32]

RES[01...32]_Bit1

RES[01...32]_Bit2

RES[01...32]_Bit3

RES[01...32]_Bit4

RES[01...32]_Bit5

RES[01...32]_Bit6

RES[01...32]_Bit7

RES[01...32]_Bit8

Once enabled, the RES data points are transported cyclically via X2X Link. They are used to transfer information from the reACTION program to the CPU.

Information:

RES data points DO NOT map the module's input directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | |
|-------------------|-------------------|------------------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 5119 + Index * 8 | RES01 | (U)SINT | • | | | |
| | RES[02...32] | | | | | |
| | RES01_Bit1 | Bit 0 | | | | |
| | RES[02...32]_Bit1 | | | | | |
| | RES01_Bit2 | Bit 1 | | | | |
| | RES[02...32]_Bit2 | | | | | |
| | RES01_Bit3 | Bit 2 | | | | |
| | RES[02...32]_Bit3 | | | | | |
| | RES01_Bit4 | Bit 3 | | | | |
| | RES[02...32]_Bit4 | | | | | |
| | RES01_Bit5 | Bit 4 | | | | |
| | RES[02...32]_Bit5 | | | | | |
| | RES01_Bit6 | Bit 5 | | | | |
| RES[02...32]_Bit6 | | | | | | |
| 5118 + Index * 8 | RES01 | (U)INT | • | | | |
| | RES[02...32] | | | | | |
| 5116 + Index * 8 | RES01 | (U)DINT, REAL | • | | | |
| | RES[02...32] | | | | | |

9.28.6.11.8.3 PVAR and RVAR data points

Name:

PVAR[1...256]

RVAR[1...256]

In addition to PAR and RES data points, VAR data points can also be defined in the reACTION program. They are a direct component of the reACTION program and can be accessed acyclically by the CPU. Like the PAR and RES data points, PVAR data points are used to transfer information from the CPU to the reACTION program. RVAR data points are used to transfer feedback from the reACTION program to the CPU.

| Data type | Value |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

| Register | Name | Data type | Read | | Write | |
|------------------|------------------------|------------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 6140 + Index * 8 | PVAR1 PVAR[2...256] | DINT, REAL | | | | • |
| 6140 + Index * 8 | RVAR1 RVAR[2...256] | DINT, REAL | | • | | |

9.28.6.11.9 reACTION function blocks - General

The following tables provide an overview of I/O channel assignments to reACTION function blocks.

Digital inputs/outputs

| Channel | Function block | | |
|-----------------|-----------------------|-----------|----------------------|
| | Mapping ¹⁾ | rTiDin | rTiDout, rTiDoutTime |
| X1: DI 1 | 0x00 | Channel 1 | |
| X1: DI 2 | 0x01 | Channel 2 | |
| X1: DI 3 / DO 3 | 0x02 | Channel 3 | Channel 3 |
| X1: DI 4 / DO 4 | 0x03 | Channel 4 | Channel 4 |
| X1: DI 5 | 0x04 | Channel 5 | |
| X1: DI 6 | 0x05 | Channel 6 | |
| X1: DI 7 / DO 7 | 0x06 | Channel 7 | Channel 7 |
| X1: DI 8 / DO 8 | 0x07 | Channel 8 | Channel 8 |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see "reACTION function blocks - Configuration" on page 3569).

Analog inputs

| Channel | Function block | | |
|----------|-----------------------|-----------|---------|
| | Mapping ¹⁾ | rTiAin | rTiAout |
| X2: AI 1 | 0x00 | Channel 1 | |
| X2: AI 2 | 0x01 | Channel 2 | |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see "reACTION function blocks - Configuration" on page 3569).

Analog output

| Channel | Function block | | |
|----------|-----------------------|--------|-----------|
| | Mapping ¹⁾ | rTiAin | rTiAout |
| X2: AO 1 | 0x00 | | Channel 1 |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see "reACTION function blocks - Configuration" on page 3569).

9.28.6.11.10 reACTION function blocks - Configuration

Some function blocks in library AsIoRti must be configured before they can be used.

| Function block | Information |
|----------------|--|
| rtiABRPos | The module offers the option of using function block rtiABRPos once in the reACTION program. To do so, the function block must be assigned 3 digital inputs that are no longer available for rtiDin. |
| rtiABCnt | The module offers the option of using function block rtiABCnt up to 3 times in the reACTION program. To do so, the function blocks must be assigned 2 digital inputs as an A or B track that are no longer available for rtiDin. In addition, an external event can be defined for each rtiABCnt function block. The input used for this is also no longer available for rtiDin. |

Table 613: List of function blocks requiring prior configuration

9.28.6.11.10.1 Function blocks rtiABRPos and rtiABCnt

Function blocks rtiABRPos and rtiABCnt can be used to process the position value of an ABR incremental encoder in a reACTION task. Several hardware channels of the module are used for this. The incoming signals are interpreted by the reACTION engine and converted into a location.

The update rate depends on both the reACTION engine and the hardware used. The reACTION engine is basically able to calculate positions with an update rate of up to 8 MHz. The input frequencies of the hardware inputs can be taken from the technical data of the respective module.

These function blocks can be used separately or in combination.

Using function block rtiABRPos

The following points are important to keep in mind when using function block rtiABRPos in a reACTION program:

- The function block can only be used once in a reACTION program.
- 3 digital inputs must be defined on the module for input signals A, B and R.
- In addition, a digital input of the module can be defined as an event input.

Example diagram of input signals:

Figure 351: Schematic diagram of input signals for rtiABRPos

Using function block rtiABCnt

The following points must be taken into account when using function block rtiABCnt in a reACTION program:

- The function block can be used up to 3 times in a reACTION program.
- 2 digital inputs must be defined on the module for input signals A and B.
- In addition, up to 3 digital inputs on the module can be defined as event inputs E1, E2 and E3.

Example diagram of input signals:

Figure 352: Schematic diagram of input signals for rtiABCnt

Using function blocks rtiABRPos and rtiABCnt in combination

The following points should be kept in mind when using function blocks rtiABRPos and rtiABCnt together in a reACTION program.

- Function block rtiABRPos can only be used once in a reACTION program.
- Function block rtiABCnt can be used up to 2 times in a reACTION program.
- 3 digital inputs must be defined for input signals A, B and R (rtiABRPos).
- The same digital inputs are used for input signals A and B (rtiABCnt).
- In addition, up to 3 event inputs E1, E2 and E3 can be defined (rtiABCnt).
- E1 is used for the event input (rtiABRPos).

Example diagram of input signals:

Figure 353: Diagram of input signals when using rtiABRPos and rtiABCnt at the same time

Registering the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_Config_ABR1

This register specifies the technical characteristics of the connected ABR incremental encoder.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|------------|---|
| 0 - 15 | Increments per revolution | 0 to 65535 | Reference pulse monitoring: If the reference pulse is different than defined here, this is indicated on the status output of function block rtiABRPos. |
| 16 | Inversion of the counting direction set by signals A and B | 0 | Positive counting direction |
| | | 1 | Negative counting direction |
| 17 - 31 | Reserved | 0 | |

Wiring the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_ChannelMapping1_ABR1

CfO_ChannelMapping2_ABR1

Before function blocks rtiABRPos/rtiABCnt can be processed by the reACTION engine, the hardware inputs to be used by the ABR incremental encoder must be defined on the module. The "ChannelMapping" registers specify which inputs are interpreted as the A, B, R, E1, E2 and E3 signals.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure of CfO_ChannelMapping1_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---------------------------------------|
| 0 - 7 | Input E1 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 8 - 15 | Input R | 0 to 255 | For possible values, see bits 0 to 7. |
| 16 - 23 | Input B | 0 to 255 | For possible values, see bits 0 to 7. |
| 24 - 31 | Input A | 0 to 255 | For possible values, see bits 0 to 7. |

Bit structure of CfO_ChannelMapping2_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---|
| 0 - 15 | Reserved | 0 | |
| 16 - 23 | Input E3 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 24 - 31 | Input E2 | 0 to 255 | For possible values, see bits 16 to 23. |

Information:

For information about the relationship between the input on the module and the channel name, see section "reACTION function blocks - General".

Scaling the position encoder (rtiABRPos)

Name:

CfO_ScalingUnits_ABR1

CfO_ScalingIncrements_ABR1

An optional gear ratio can be configured using registers "Units" and "Increments". The dividend for scaling is defined in register "Units"; the divisor is defined in register "Increments".

| Data type | Value | Information |
|-----------|--------------------|--|
| UDINT | 0 to 4,294,967,295 | CfO_ScalingUnits_ABR1: Units per interval CfO_ScalingIncrements_ABR1: Increments per interval |

Formula for calculation

$$\text{Gear ratio} = \text{ScalingUnits} / \text{ScalingIncrements}$$
Example 1

ScalingUnits = 1

ScalingIncrements = 1

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 1/1$$

In this example, the ABR position value is output unchanged on output "Pos".

Example 2

ScalingUnits = 10

ScalingIncrements = 4

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 10/4$$

In this example, the ABR position value is multiplied by 2.5 and output on output "Pos".

Information:

The encoder values are calculated internally as INT64 values in 32.32 format. On output "Pos" of function block "rtiABRPos", only the whole number value (INT32) is output for the user. The fixed point decimal places are used internally to calculate a higher resolution.

9.28.6.11.11 Direct I/O - Configuration

This module is equipped with 8 digital channels, 2 analog inputs and 1 analog output. In the "Direct I/O" function model, behavior is based on that of a standard module. The I/O channels are managed by an extremely simplified reACTION program. The function model primarily serves to check that the I/O channels are functioning properly.

9.28.6.11.11.1 Direction of digital channels

Name:

CfO_DigitalDirection

This register determines the signal direction of digital channels 3, 4, 7 and 8.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-------------------------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | Direction - Digital channel 3 | 0 | Input |
| | | 1 | Output |
| 3 | Direction - Digital channel 4 | 0 | Input |
| | | 1 | Output |
| 4 - 5 | Reserved | 0 | |
| 6 | Direction - Digital channel 7 | 0 | Input |
| | | 1 | Output |
| 7 | Direction - Digital channel 8 | 0 | Input |
| | | 1 | Output |

9.28.6.11.11.2 Filtering digital channels

Name:

CfO_DigitalFilter

This register defines the filter time of the digital channels. The filter value affects both the switching delay as well as the immunity of the channels.

| Data type | Value |
|-----------|--------------------------|
| UDINT | 0 to 500000: Units 10 ns |

9.28.6.11.11.3 Filtering analog inputs

Name:

CfO_AnalogFilter01 to CfO_AnalogFilter02

This register sets the filter level of the analog input.

| Data type | Values |
|-----------|--------|
| UDINT | 0 to 7 |

$$2^{\text{AnalogFilter}} = \text{FilterLevel} = \frac{\text{Out(ADC)}_t - \text{Out(Filter)}_{t-1}}{\text{Out(Filter)}_t - \text{Out(Filter)}_{t-1}} \cong \frac{\Delta \text{Out(ADC)}}{\Delta \text{Out(Filter)}}$$

The filter level results as the exponent to base 2 and corresponds to the ratio of the change of the digitalized input value to the change of the filtered analog value.

9.28.6.11.11.4 Limit values of the analog inputs

Name:

CfO_LowerLimit01 to CfO_LowerLimit02

CfO_UpperLimit01 to CfO_UpperLimit02

These registers define the upper and lower user-specific limit values for the analog input.

| Data type | Values |
|-----------|---|
| DINT | LowerLimit: -32767 to 32767 (Default: -32767) UpperLimit: -32767 to 32767 (Default: 32767) |

9.28.6.11.12 Direct I/O - Communication

This module is equipped with the following inputs and outputs:

- 4 digital inputs (sink) for 24 VDC
- 4 digital channels configurable as inputs (sink) or outputs (sink or source) for 24 VDC
- 2 analog inputs of type ± 10 V
- 1 analog output of type ± 10 V

9.28.6.11.12.1 Digital outputs

Name:

DigitalOutput03

DigitalOutput04

DigitalOutput07

DigitalOutput08

This register is used to predefine the value that should be output on the digital output.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | DigitalOutput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalOutput04 | 0 | FALSE |
| | | 1 | TRUE |
| 4 - 5 | Reserved | 0 | |
| 6 | DigitalOutput07 | 0 | FALSE |
| | | 1 | TRUE |
| 7 | DigitalOutput08 | 0 | FALSE |
| | | 1 | TRUE |

9.28.6.11.12.2 Digital inputs

Name:

DigitalInput01

DigitalInput02

DigitalInput03

DigitalInput04

DigitalInput05

DigitalInput06

DigitalInput07

DigitalInput08

This register indicates the value read for the respective digital input.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------|-------|-------------|
| 0 | DigitalInput01 | 0 | FALSE |
| | | 1 | TRUE |
| 1 | DigitalInput02 | 0 | FALSE |
| | | 1 | TRUE |
| 2 | DigitalInput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalInput04 | 0 | FALSE |
| | | 1 | TRUE |
| 4 | DigitalInput05 | 0 | FALSE |
| | | 1 | TRUE |
| 5 | DigitalInput06 | 0 | FALSE |
| | | 1 | TRUE |
| 6 | DigitalInput07 | 0 | FALSE |
| | | 1 | TRUE |
| 7 | DigitalInput08 | 0 | FALSE |
| | | 1 | TRUE |

9.28.6.11.12.3 Analog inputs

Name:

AnalogInput01 to AnalogInput02

This register contains the analog input value.

| Data type | Values |
|-----------|-----------------|
| INT | -32767 to 32767 |

9.28.6.11.12.4 Analog output

Name:

AnalogOutput01

This register defines the value for the analog output.

| Data type | Values |
|-----------|-----------------|
| INT | -32767 to 32767 |

9.28.6.11.13 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.28.6.11.14 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 200 μ s |

9.28.7 X20RT8401

Data sheet version: 1.14

9.28.7.1 General information

This reACTION technology module has 4 high-speed digital inputs and 4 high-speed digital mixed channels. All connections are designed for 1-wire connections. All inputs are designed for sink connections; the outputs are designed for push-pull connections.

A voltage signal of ± 10 V can be read or output using an analog input and analog output, respectively.

Ultrafast reACTION Technology makes it possible to control the integrated I/O channels with response times down to 1 μ s. All of the commands that can be used for reACTION programs are provided as function blocks in special libraries (e.g. AsIORTI). Programming in compliance with IEC 61131-3 requirements takes place in the Function Block Diagram editor in Automation Studio.

The module supports blackout mode. In blackout mode, programmable module functionality persists even if the network fails.

- reACTION technology module
- 4 high-speed digital inputs
- 4 high-speed digital channels, configurable as inputs or outputs
- 1 high-speed analog input ± 10 V
- 1 high-speed analog output ± 10 V
- 1 ABR incremental encoder input 24 V
- Pulse width modulation
- 24 VDC and GND for encoder supply
- Supports blackout mode

9.28.7.2 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | reACTION Technology modules |  |
| X20RT8401 | X20 reACTION module, 4 digital inputs, 24 VDC, <1 μ s, 4 digital channels, 24 VDC, 0.1 A, <1 μ s, configurable as inputs or outputs, 1 analog input ± 10 V, 500 kHz sampling frequency, 13-bit converter resolution including sign, configurable input filter, 1 analog output ± 10 V, 2 μ s, 13-bit converter resolution including sign, reACTION Technology module | |
| | Required accessories | |
| | Bus modules | |
| X20BM31 | X20 bus module for double-width modules, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |

| Common-mode rejection | |
| DC | 86 dB |
| 50 Hz | 84 dB |
| Common-mode range | ±12 V |
| Nonlinearity | 0.015% ⁵⁾ |
| Isolation voltage between channel and bus | 500 V _{eff} |
| Sampling frequency | 500 kHz |
| Digital outputs | |
| Quantity ²⁾ | 4 mixed channels, configurable as inputs or outputs using software |
| Variant | Push-Pull |
| Nominal voltage | 24 VDC |
| Switching voltage | 24 VDC -15% / +20% |
| Nominal output current | 100 mA |
| Total nominal current | 400 mA |
| Connection type | 1-wire connections |
| Output circuit | Sink or source |
| Output protection | Thermal cutoff if overcurrent or short circuit occurs (see value "Peak short circuit current") |
| Diagnostic status | Output monitoring with delay <700 ns |
| Leakage current when switched off | Approx. 25 µA |
| R _{DS(on)} | 140 mΩ |
| Residual voltage | <0.4 V at nominal current 100 mA |
| Max. continuous current | 100 mA |
| Peak short-circuit current | <10 A |
| Switch-on in the event of overload shutdown or short-circuit shutdown | Approx. 3 ms |
| Switching delay | |
| 0 → 1 | <1 µs |
| 1 → 0 | <1 µs |
| Switching frequency | |
| Resistive load | Min. 50 kHz, max. 500 kHz |
| Isolation voltage between channel and bus | 500 V _{eff} |
| Analog outputs | |
| Quantity | 1 |
| Output | ±10 V |
| Digital converter resolution | ±12-bit |
| Conversion time | 2 µs |
| Settling time for output changes over entire range | 5 µs |
| Switch on/off behavior | Internal enable relay for startup |
| Max. error at 25°C | |
| Gain | 0.15% ⁶⁾ |
| Offset | 0.05% ⁷⁾ |
| Output protection | Short circuit protection |
| Output format | |
| Data type | INT |
| Voltage | INT 0x8000 - 0x7FFF / 1 LSB = 0x0008 = 2.441 mV |
| Load per channel | Max. ±10 mA, load ≥1 kΩ |
| Short-circuit proof | Current limiting ±65 mA |
| Output filter | 1st-order low pass / cutoff frequency 22 kHz |
| Max. gain drift | 0.022 %/°C ⁶⁾ |
| Max. offset drift | 0.032 %/°C ⁷⁾ |
| Error caused by load change | Max. 0.14%, from 10 MΩ → 1 kΩ, resistive |
| Nonlinearity | 0.005% ⁸⁾ |
| Isolation voltage between channel and bus | 500 V _{eff} |
| Electrical properties | |
| Electrical isolation | Channel isolated from bus Channel not isolated from channel |
| Operating conditions | |
| Mounting orientation | |
| Horizontal | Yes |
| Vertical | Yes |
| Installation elevation above sea level | |
| 0 to 2000 m | No limitation |
| >2000 m | Reduction of ambient temperature by 0.5°C per 100 m |

Table 615: X20RT8401 - Technical data

| Model number | X20RT8401 |
|-----------------------------------|--|
| Degree of protection per EN 60529 | IP20 |
| Ambient conditions | |
| Temperature | |
| Operation | |
| Horizontal mounting orientation | -25 to 60°C |
| Vertical mounting orientation | -25 to 50°C |

Table 615: X20RT8401 - Technical data

- 1) See section "X20 shielding brackets".
- 2) See section "Derating and hardware configuration".
- 3) To reduce power dissipation, B&R recommends bridging unused inputs on the terminal.
- 4) Based on the current measured value.
- 5) Based on the 20 V measurement range.
- 6) Based on the current output value.
- 7) Based on the entire output range.
- 8) Based on the output range.

9.28.7.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|------------|---|------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode or blackout mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | Warning/Error on an I/O channel. Level monitoring of digital outputs has been triggered. |
| | | | Double flash | Supply voltage not in valid range or no reACTION program loaded |
| | | | Triple flash | Test of internal memory failed (limited functionality, module must be replaced) |
| | On | Error or reset state (reACTION program using functions or channels that are not permitted on this hardware) | | |
| | e + r | Solid red / Single green flash | Invalid firmware | |
| | 1, 2, 5, 6 | Green | | Input state of the corresponding digital input |
| | 3, 4, 7, 8 | Green | | Input or output status of the corresponding digital input or output |

Table 616: LED status indicators (X1)

1) A firmware update can take several minutes depending on the configuration.

| Figure | LED | Color | Status | Description |
|--|-----|--------|----------|--|
|  | 1 | Green | Off | Open circuit or disconnected sensor |
| | | | Blinking | Input signal overflow or underflow |
| | | | On | Analog/digital converter running, value OK |
| | 1 | Orange | Off | Value = 0 |
| | | | On | Value ≠ 0 |

Table 617: LED status indicators (X2)

9.28.7.5 Pinout

9.28.7.5.1 X1 - Pinout

To prevent crosstalk, each individual signal line should be shielded. The maximum cable length is 20 m.

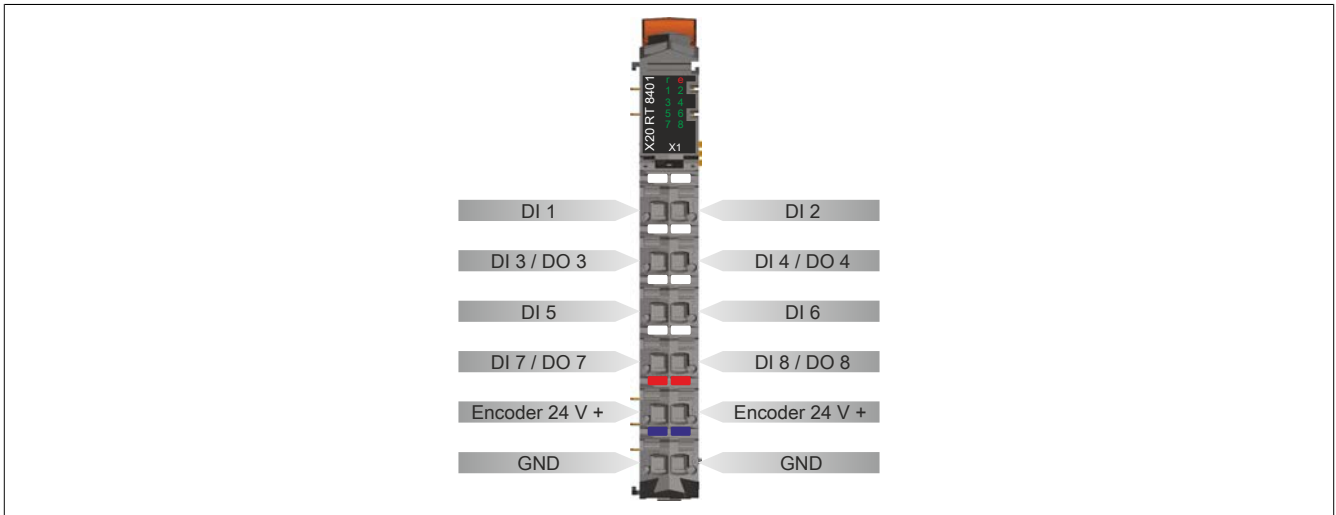

Figure 354: X1 - Pinout

9.28.7.5.2 X2 - Pinout

To prevent crosstalk, each individual signal line should be shielded. The maximum cable length is 20 m.

Figure 355: X2 - Pinout

9.28.7.6 Local I/O channels

The following tables provide an overview of the connections to the I/O channels.

Digital inputs/outputs

| Connection | Terminal connection | Channel |
|------------|---------------------|-------------|
| X1 | 11 | DI 1 |
| | 21 | DI 2 |
| | 12 | DI 3 / DO 3 |
| | 22 | DI 4 / DO 4 |
| | 13 | DI 5 |
| | 23 | DI 6 |
| | 14 | DI 7 / DO 7 |
| | 24 | DI 8 / DO 8 |

Analog input

| Connection | Terminal connection | Channel |
|------------|---------------------|---------|
| X2 | 11 and 12 | AI 1 |

Analog output

| Connection | Terminal connection | Channel |
|------------|---------------------|---------|
| X2 | 13 and 14 | AO 1 |

The following sections describe assigning I/O channels in a reACTION program:

| I/O channels | Assignment |
|-----------------------|--|
| Digital I/O channels | Assignment of digital inputs/outputs |
| Analog input channel | Assignment of analog input |
| Analog output channel | Assignment of analog output |

9.28.7.7 Connection examples

9.28.7.7.1 X1 - Connection examples

Digital inputs and digital outputs

9.28.7.9 Derating and hardware configuration

To ensure proper operation, observe the points listed below:

- Derating of the encoder current
- Number of operable digital outputs
- Hardware configurations

9.28.7.9.1 Derating of the encoder current

Observe the following derating values for the encoder current depending on the mounting orientation:

9.28.7.9.2 Number of operable digital outputs

Depending on the mounting orientation, not all 4 digital outputs of the module can be operated starting at a certain ambient temperature.

Information:

To ensure operation of the module with the ambient temperatures listed below, it is absolutely necessary to disconnect channels.

Reducing the output current per channel does not increase the number of digital output channels that can be operated in the corresponding ambient temperature class.

Horizontal installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <45°C | 4 |
| Starting at 45°C | 3 |
| Starting at 55°C | 2 |

Vertical installation

| Ambient temperature | Number of operable digital outputs |
|---------------------|------------------------------------|
| <35°C | 4 |
| Starting at 35°C | 3 |
| Starting at 45°C | 2 |

9.28.7.9.3 Hardware configuration for horizontal installation

9.28.7.9.3.1 Hardware configuration starting at an ambient temperature of 50°C

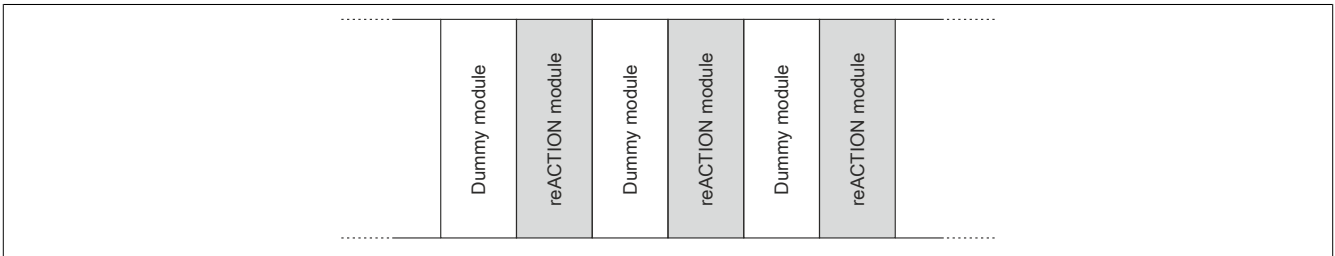

Operating a reACTION module

Starting at an ambient temperature of 50°C, a dummy module must be connected to the left of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.7.9.3.2 Hardware configuration starting at an ambient temperature of 55°C

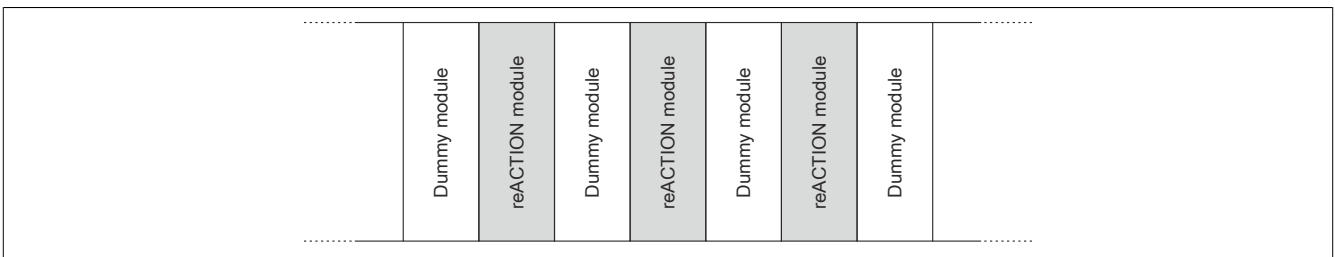

Operating a reACTION module

Starting at an ambient temperature of 55°C, a dummy module must be connected to the left and right of the reACTION module if installed horizontally.

Operating multiple reACTION modules side by side

If 2 or more horizontal reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.7.9.4 Hardware configuration for vertical installation

9.28.7.9.4.1 Hardware configuration starting at an ambient temperature of 40°C

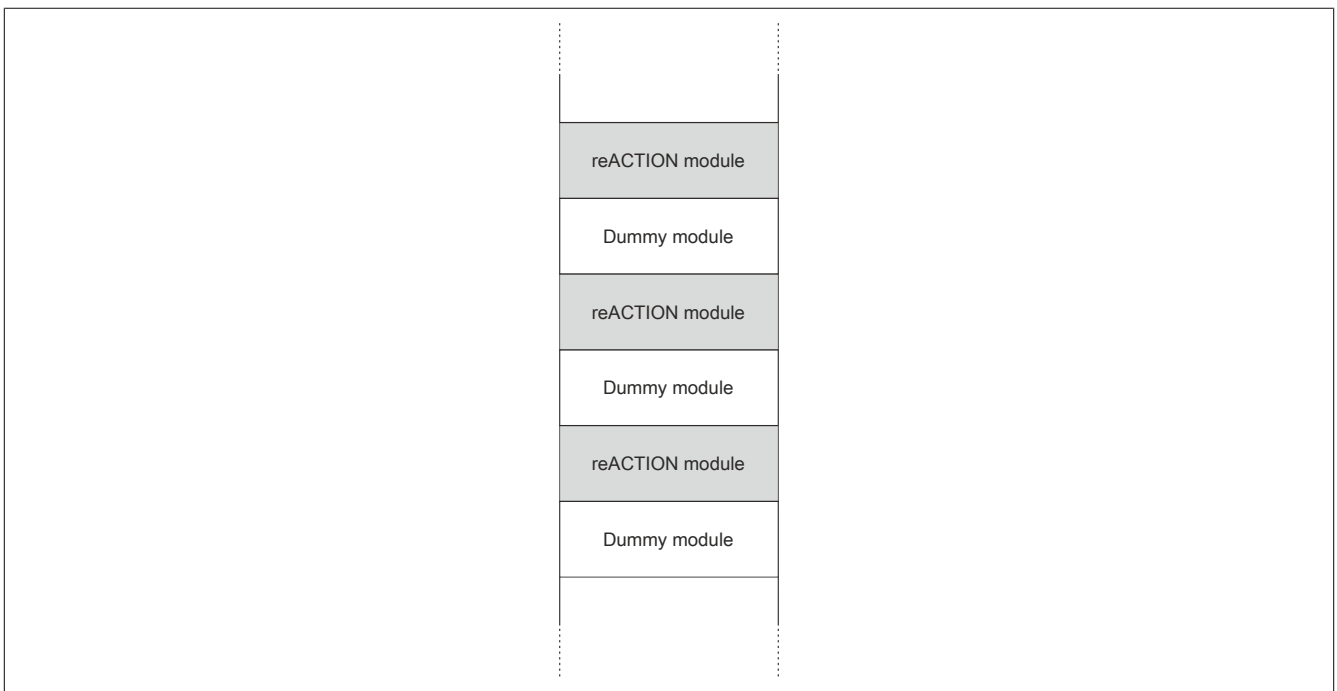

Operating a reACTION module

At ambient temperatures starting at 40°C, a dummy module must be installed below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.7.9.4.2 Hardware configuration starting at an ambient temperature of 45°C

Operating a reACTION module

At ambient temperatures starting at 45°C, dummy modules must be installed above and below the reACTION module if installed vertically.

Operating multiple reACTION modules side by side

If 2 or more vertical reACTION modules are being operated in a cluster, the following arrangement of modules must be observed.

9.28.7.10 Enabling blackout mode

The following steps must be carried out to enable blackout mode.

Requirements

- reACTION program transferred to reACTION module
- Reset triggered on reACTION module:
This ensures that the program stored in the reACTION memory will be loaded with every subsequent reset.

Enabling

- Set the enable register for blackout mode.
- Control bit "RTEnable" must be set. This bit starts the reACTION engine.

Activation

- A connection error triggers a reset on the reACTION module.
- PAR and VAR data points are set to 0.
- Blackout mode is enabled on the reACTION module.

9.28.7.10.1 Blackout mode

For a description of blackout mode, see ["Blackout mode" on page 3794](#).

9.28.7.11 Register description

9.28.7.11.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.28.7.11.2 Function model 0 - "reACTION"

When using the "reACTION" function model, an individual reACTION program must be created for the module. This program will be executed by the reACTION module later on, not by the CPU. This allows individual machine tasks to be managed decentrally and with a very short response time.

The inputs and outputs of a reACTION module can only be operated by an enabled reACTION program. Interaction registers allow information to be exchanged between the CPU and the reACTION program in the module.

In addition to communication with the CPU, the cyclic interaction registers can also be used for "cross-mapping". In this way, inputs/outputs can also be read/controlled by external modules across the entire X2X Link or POWERLINK network.

| Register | Name | Data type | Read | | Write | |

9.28.7.11.3 Function model 254 - "Direct I/O"

In the "Direct I/O" function model, a special reACTION program is executed in the module in order to manage the I/O. In addition, cyclic registers are used to exchange information with the CPU. This reproduces the behavior of a standard module.

| Register | Name | Data type | Read | | Write | |
|---------------------------------|---------------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module communication | | | | | | |

9.28.7.11.4 Module communication

9.28.7.11.4.1 Module status messages

Name:

ModuleStatus

This register is used to transfer general status messages for the module.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|--------------------------------------|---------------------|-------|---|
| Status word - Module (L byte) | | | |
| 0 | SensorSupplyOk_X1 | 0 | (Encoder) power supply for X1 faulty |
| | | 1 | No error |
| 1 | InternalSupplyOk_X1 | 0 | Internal voltage conversion for X1 faulty |
| | | 1 | No error |
| 2 | SensorSupplyOk_X2 | 0 | Power supply for X2 faulty |
| | | 1 | No error |
| 3 | InternalSupplyOk_X2 | 0 | Internal voltage conversion for X2 faulty |
| | | 1 | No error |
| 4 - 5 | Reserved | - | |
| 6 | X1ToX2ComError | 0 | No error |
| | | 1 | X1 → X2 communication faulty |
| 7 | X2ToX1ComError | 0 | No error |
| | | 1 | X2 → X1 communication faulty |
| Status word - Module (H byte) | | | |
| 0 | AnalogIn01ComError | 0 | No error |
| | | 1 | Value from analog input 1 faulty |
| 1 - 3 | Reserved | - | |
| 4 | AnalogOut01ComError | 0 | No error |
| | | 1 | Value from analog output 1 faulty |
| 5 - 7 | Reserved | - | |

9.28.7.11.4.2 Status messages for the digital channels

Name:

DigitalStatus

This register is used to transfer general status messages for the digital channels.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|---------------------------------------|------------------------|-------|---|
| Status word - Digital (L byte) | | | |
| 0 - 1 | Reserved | - | |
| 2 | DigitalOutput3Overload | 0 | Digital output 3 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 3 | DigitalOutput4Overload | 0 | Digital output 4 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 4 - 5 | Reserved | - | |
| 6 | DigitalOutput7Overload | 0 | Digital output 7 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |
| 7 | DigitalOutput8Overload | 0 | Digital output 8 OK |
| | | 1 | Requested voltage 0 V/24 V not achieved |

9.28.7.11.4.3 Status messages of the analog input

Name:

AnalogInputStatus

This register transfers general status messages of the analog input.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|--|---------------------|-------|--|
| Status word - AnalogIn (L byte) | | | |
| 0 | AnalogIn01Underflow | 0 | No error |
| | | 1 | Lower limit value from analog input 1 underrun |
| 1 | AnalogIn01Overflow | 0 | No error |
| | | 1 | Upper limit value from analog input 1 exceeded |
| 2 | AnalogIn01OpenLoop | 0 | No error |
| | | 1 | Open circuit determined on analog input 1 |
| 3 - 7 | Reserved | - | |

9.28.7.11.5 reACTION - Configuration

9.28.7.11.5.1 reACTION cycle time

Name:

ReActionCycleTimeValue

ReActionCycleTimeMultiplier

Registers "TimeValue" and "Multiplier" predefine the desired cycle time for the reACTION program. Register "TimeValue" contains the value, while register "Multiplier" contains the associated units.

Register "Multiplier" is currently permanently set to 1000 in order to predefine the cycle time with μ s precision.

| Data type | Value |
|-----------|------------|
| UDINT | 1 to 10000 |

9.28.7.11.5.2 Configuring the PAR data points

Name:

CfO_PARType01

CfO_PARType[02...04]

PAR data points can be defined for the reACTION program. To enable them, the desired data type must be made known according to the configuration in Automation Studio.

| Data type | Value |
|-----------|-------------------|
| UDINT | See bit structure |

Bit structure:

| Bit | Name | Value | Information |
|---------|-----------------|-------|-------------|
| 0 - 3 | Type01 - PAR 1 | 0000 | Inactive |
| | Type02 - PAR 9 | 0001 | USINT, BOOL |
| | Type03 - PAR 17 | | |
| | Type04 - PAR 25 | | |
| 4 - 7 | Type01 - PAR 2 | 0010 | UINT |
| | Type02 - PAR 10 | 0011 | UDINT |
| | Type03 - PAR 18 | | |
| | Type04 - PAR 26 | | |
| 8 - 11 | Type01 - PAR 3 | 0100 | Reserved |
| | Type02 - PAR 11 | 0101 | SINT |
| | Type03 - PAR 19 | | |
| | Type04 - PAR 27 | | |
| 12 - 15 | Type01 - PAR 4 | 0110 | INT |
| | Type02 - PAR 12 | 0111 | DINT |
| | Type03 - PAR 20 | | |
| | Type04 - PAR 28 | | |
| 16 - 19 | Type01 - PAR 5 | 1000 | Reserved |
| | Type02 - PAR 13 | ... | |
| | Type03 - PAR 21 | 1111 | |
| | Type04 - PAR 29 | | |
| 20 - 23 | Type01 - PAR 6 | | |
| | Type02 - PAR 14 | | |
| | Type03 - PAR 22 | | |
| | Type04 - PAR 30 | | |
| 24 - 27 | Type01 - PAR 7 | | |
| | Type02 - PAR 15 | | |
| | Type03 - PAR 23 | | |
| | Type04 - PAR 31 | | |
| 28 - 31 | Type01 - PAR 8 | | |
| | Type02 - PAR 16 | | |
| | Type03 - PAR 24 | | |
| | Type04 - PAR 32 | | |

9.28.7.11.6 reACTION - Communication

At runtime, the reACTION module program is controlled via the program sequence in the CPU. In its active state, the reACTION program is then executed independently of the program sequence in the CPU.

9.28.7.11.6.1 Controlling the reACTION module

Name:

RTEnable

RTHardwareWarningQuit

This register controls the reACTION program.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------------|-------|--|
| 0 | RTEnable | 0 | Stops the reACTION program |
| | | 1 | Starts the reACTION program |
| 1 | Reserved | - | |
| 2 | RTHardwareWarningQuit | 0 | No effect |
| | | 1 | Acknowledges warning messages for the inputs and outputs |
| 3 - 7 | Reserved | - | |

9.28.7.11.6.2 reACTION module status messages

Name:

RTEngineRun

RTCycleTimeOverrun

RTHardwareWarning

RTFileInvalid

RTFunctionInvalid

RTInstanceInvalid

RTFileNotLoaded

This register is used to output various status messages.

| Data type | Value |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|---|-------|--|
| 0 | RTEngineRun | 0 | reACTION program inactive |
| | | 1 | reACTION program active |
| 1 | RTCycleTimeOverrun | 0 | Configured RT cycle time observed |
| | | 1 | RT cycle time set too short |
| 2 | RTHardwareWarning (group bit for acyclic status data points) | 0 | No status messages |
| | | 1 | Warning message for the inputs and outputs |
| 3 | Reserved | - | |
| 4 | RTFileInvalid (invalid RT program preloaded) | 0 | RT program in RAM OK |
| | | 1 | RT program in RAM invalid |
| 5 | RTFunctionInvalid (invalid software function) | 0 | RT program OK |
| | | 1 | RT program requesting invalid function block |
| 6 | RTInstanceInvalid (invalid hardware instance) | 0 | RT program OK |
| | | 1 | RT program requesting invalid I/O |
| 7 | RTFileNotLoaded | 0 | Valid RT program in RT engine |
| | | 1 | No RT program loaded |

9.28.7.11.6.3 Cycle counter for the active reACTION program

Name:

RTCycleCounter

Register "CycleCounter" can be used to determine how often the reACTION program has cycled.

| Data type | Value |
|-----------|------------|
| UINT | 0 to 65535 |

9.28.7.11.6.4 Minimum cycle time of the active reACTION program

Name:

RTCycleTime

Register "RTCycleTime" can be used to determine how much time the reACTION module needs to cycle through the loaded program once.

| Data type | Value |
|-----------|-------------------------|
| UINT | 0 to 65535: Units 10 ns |

9.28.7.11.7 reACTION - Interaction

After startup, the reACTION program in the module runs independently. It reads the images of the required inputs and manages its assigned outputs throughout the entire network. In addition, the reACTION program can interact with the CPU. There are 3 different data point types available for this.

9.28.7.11.7.1 PAR data points

Name:

PAR[01...32]

PAR[01...32]_Bit1

PAR[01...32]_Bit2

PAR[01...32]_Bit3

PAR[01...32]_Bit4

PAR[01...32]_Bit5

PAR[01...32]_Bit6

PAR[01...32]_Bit7

PAR[01...32]_Bit8

Once enabled, the PAR data points are transported cyclically via X2X Link. They are used to transfer information from the CPU to the reACTION program. They can be used to intervene in the execution of the reACTION program.

Information:

PAR data points DO NOT control the module's outputs directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | | |
|------------------|---------------------------------|-----------------------|---------|---------|--------|---------|--|
| | | | Cyclic | Acyclic | Cyclic | Acyclic | |
| 4095 + Index * 8 | PAR01 PAR[02...32] | (U)SINT | | | • | | |
| | PAR01_Bit1 PAR[02...32]_Bit1 | Bit 0 | | | | | |
| | PAR01_Bit2 PAR[02...32]_Bit2 | Bit 1 | | | | | |
| | PAR01_Bit3 PAR[02...32]_Bit3 | Bit 2 | | | | | |
| | PAR01_Bit4 PAR[02...32]_Bit4 | Bit 3 | | | | | |
| | PAR01_Bit5 PAR[02...32]_Bit5 | Bit 4 | | | | | |
| | PAR01_Bit6 PAR[02...32]_Bit6 | Bit 5 | | | | | |
| | PAR01_Bit7 PAR[02...32]_Bit7 | Bit 6 | | | | | |
| | PAR01_Bit8 PAR[02...32]_Bit8 | Bit 7 | | | | | |
| | 4094 + Index * 8 | PAR01 PAR[02...32] | (U)INT | | | • | |
| | 4092 + Index * 8 | PAR01 PAR[02...32] | (U)DINT | | | • | |

9.28.7.11.7.2 RES data points

Name:

RES[01...32]

RES[01...32]_Bit1

RES[01...32]_Bit2

RES[01...32]_Bit3

RES[01...32]_Bit4

RES[01...32]_Bit5

RES[01...32]_Bit6

RES[01...32]_Bit7

RES[01...32]_Bit8

Once enabled, the RES data points are transported cyclically via X2X Link. They are used to transfer information from the reACTION program to the CPU.

Information:

RES data points DO NOT map the module's input directly!

| Data type | Value |
|---------------|-------------------------------|
| (U)SINT, BOOL | Corresponding range of values |
| (U)INT | |
| (U)DINT | |

| Register | Name | Data type | Read | | Write | |
|-------------------|-------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 5119 + Index * 8 | RES01 | (U)SINT | • | | | |
| | RES[02...32] | | | | | |
| | RES01_Bit1 | Bit 0 | | | | |
| | RES[02...32]_Bit1 | | | | | |
| | RES01_Bit2 | Bit 1 | | | | |
| | RES[02...32]_Bit2 | | | | | |
| | RES01_Bit3 | Bit 2 | | | | |
| | RES[02...32]_Bit3 | | | | | |
| | RES01_Bit4 | Bit 3 | | | | |
| | RES[02...32]_Bit4 | | | | | |
| | RES01_Bit5 | Bit 4 | | | | |
| | RES[02...32]_Bit5 | | | | | |
| | RES01_Bit6 | Bit 5 | | | | |
| RES[02...32]_Bit6 | | | | | | |
| RES01_Bit7 | Bit 6 | | | | | |
| RES[02...32]_Bit7 | | | | | | |
| RES01_Bit8 | Bit 7 | | | | | |
| RES[02...32]_Bit8 | | | | | | |
| 5118 + Index * 8 | RES01 | (U)INT | • | | | |
| | RES[02...32] | | | | | |
| 5116 + Index * 8 | RES01 | (U)DINT | • | | | |
| | RES[02...32] | | | | | |

9.28.7.11.7.3 PVAR and RVAR data points

Name:

PVAR[1...256]

RVAR[1...256]

In addition to PAR and RES data points, VAR data points can also be defined in the reACTION program. They are a direct component of the reACTION program and can be accessed acyclically by the CPU. Like the PAR and RES data points, the PVAR data points are used to transfer information from the CPU to the reACTION program. The RVAR data points are used to transfer feedback from the reACTION program to the CPU.

| Data type | Value |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

| Register | Name | Data type | Read | | Write | |
|------------------|------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 6140 + Index * 8 | PVAR1 PVAR[2...256] | DINT | | | | • |
| 6140 + Index * 8 | RVAR1 RVAR[2...256] | DINT | | • | | |

9.28.7.11.8 reACTION function blocks - General

The following tables provide an overview of I/O channel assignments to reACTION function blocks.

Digital inputs/outputs

| Channel | Function block | | |
|-----------------|-----------------------|-----------|----------------------|
| | Mapping ¹⁾ | rTiDin | rTiDout, rTiDoutTime |
| X1: DI 1 | 0x00 | Channel 1 | |
| X1: DI 2 | 0x01 | Channel 2 | |
| X1: DI 3 / DO 3 | 0x02 | Channel 3 | Channel 3 |
| X1: DI 4 / DO 4 | 0x03 | Channel 4 | Channel 4 |
| X1: DI 5 | 0x04 | Channel 5 | |
| X1: DI 6 | 0x05 | Channel 6 | |
| X1: DI 7 / DO 7 | 0x06 | Channel 7 | Channel 7 |
| X1: DI 8 / DO 8 | 0x07 | Channel 8 | Channel 8 |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see ["reACTION function blocks - Configuration" on page 3604](#)).

Analog input

| Channel | Function block | | |
|----------|-----------------------|-----------|---------|
| | Mapping ¹⁾ | rTiAin | rTiAout |
| X2: AI 1 | 0x00 | Channel 1 | |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see ["reACTION function blocks - Configuration" on page 3604](#)).

Analog output

| Channel | Function block | | |
|----------|-----------------------|--------|-----------|
| | Mapping ¹⁾ | rTiAin | rTiAout |
| X2: AO 1 | 0x00 | | Channel 1 |

- 1) The "Mapping" specification is needed in the event that multiple physical inputs/outputs must be grouped together in order to be processed by a reACTION function block (e.g. rTiABRPos) (see ["reACTION function blocks - Configuration" on page 3604](#)).

9.28.7.11.9 reACTION function blocks - Configuration

Some function blocks in library AsIoRti must be configured before they can be used.

| Function block | Information |
|----------------|--|
| rtiABRPos | The module offers the option of using function block rtiABRPos once in the reACTION program. To do so, the function block must be assigned 3 digital inputs that are no longer available for rtiDin. |
| rtiABCnt | The module offers the option of using function block rtiABCnt up to 3 times in the reACTION program. To do so, the function blocks must be assigned 2 digital inputs as an A or B track that are no longer available for rtiDin. In addition, an external event can be defined for each rtiABCnt function block. The input used for this is also no longer available for rtiDin. |

Table 618: List of function blocks requiring prior configuration

9.28.7.11.9.1 Function blocks rtiABRPos and rtiABCnt

Function blocks rtiABRPos and rtiABCnt can be used to process the position value of an ABR incremental encoder in a reACTION task. Several hardware channels of the module are used for this. The incoming signals are interpreted by the reACTION engine and converted into a location.

The update rate depends on both the reACTION engine and the hardware used. The reACTION engine is basically able to calculate positions with an update rate of up to 8 MHz. The input frequencies of the hardware inputs can be taken from the technical data of the respective module.

These function blocks can be used separately or in combination.

Using function block rtiABRPos

The following points are important to keep in mind when using function block rtiABRPos in a reACTION program:

- The function block can only be used once in a reACTION program.
- 3 digital inputs must be defined on the module for input signals A, B and R.
- In addition, a digital input of the module can be defined as an event input.

Example diagram of input signals:

Figure 363: Schematic diagram of input signals for rtiABRPos

Using function block rtiABCnt

The following points must be taken into account when using function block rtiABCnt in a reACTION program:

- The function block can be used up to 3 times in a reACTION program.
- 2 digital inputs must be defined on the module for input signals A and B.
- In addition, up to 3 digital inputs on the module can be defined as event inputs E1, E2 and E3.

Example diagram of input signals:

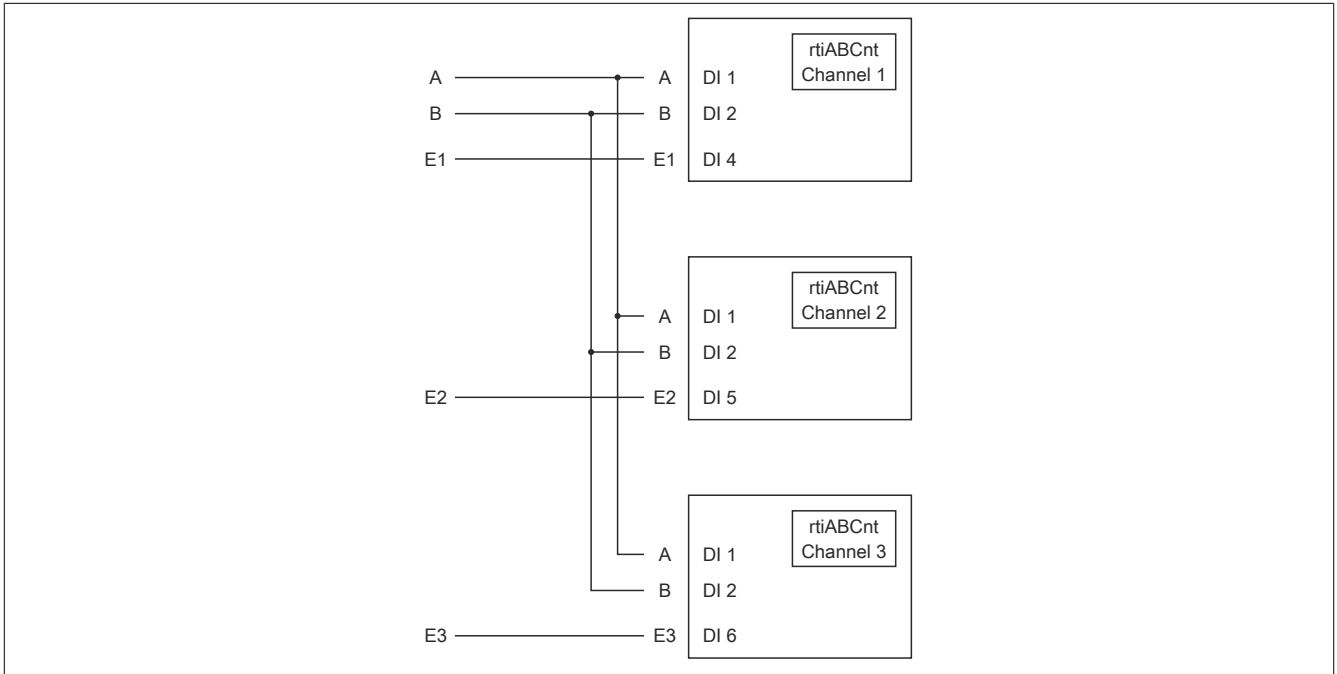

Figure 364: Schematic diagram of input signals for rtiABCnt

Using function blocks rtiABRPos and rtiABCnt in combination

The following points should be kept in mind when using function blocks rtiABRPos and rtiABCnt together in a reACTION program.

- Function block rtiABRPos can only be used once in a reACTION program.
- Function block rtiABCnt can be used up to 2 times in a reACTION program.
- 3 digital inputs must be defined for input signals A, B and R (rtiABRPos).
- The same digital inputs are used for input signals A and B (rtiABCnt).
- In addition, up to 3 event inputs E1, E2 and E3 can be defined (rtiABCnt).
- E1 is used for the event input (rtiABRPos).

Example diagram of input signals:

Figure 365: Diagram of input signals when using rtiABRPos and rtiABCnt at the same time

Registering the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_Config_ABR1

This register specifies the technical characteristics of the connected ABR incremental encoder.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|------------|---|
| 0 - 15 | Increments per revolution | 0 to 65535 | Reference pulse monitoring: If the reference pulse is different than defined here, this is indicated on the status output of function block rtiABRPos. |
| 16 | Inversion of the counting direction set by signals A and B | 0 | Positive counting direction |
| | | 1 | Negative counting direction |
| 17 - 31 | Reserved | 0 | |

Wiring the position encoder (rtiABRPos/rtiABCnt)

Name:

CfO_ChannelMapping1_ABR1

CfO_ChannelMapping2_ABR1

Before function blocks rtiABRPos/rtiABCnt can be processed by the reACTION engine, the hardware inputs to be used by the ABR incremental encoder must be defined on the module. The "ChannelMapping" registers specify which inputs are interpreted as the A, B, R, E1, E2 and E3 signals.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure of CfO_ChannelMapping1_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---------------------------------------|
| 0 - 7 | Input E1 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 8 - 15 | Input R | 0 to 255 | For possible values, see bits 0 to 7. |
| 16 - 23 | Input B | 0 to 255 | For possible values, see bits 0 to 7. |
| 24 - 31 | Input A | 0 to 255 | For possible values, see bits 0 to 7. |

Bit structure of CfO_ChannelMapping2_ABR1:

| Bit | Description | Value | Information |
|---------|-------------|----------|---|
| 0 - 15 | Reserved | 0 | |
| 16 - 23 | Input E3 | 0 | Mapped to digital input 1 |
| | | 1 | Mapped to digital input 2 |
| | | ... | ... |
| | | 7 | Mapped to digital input 8 |
| | | 8 to 255 | Reserved |
| 24 - 31 | Input E2 | 0 to 255 | For possible values, see bits 16 to 23. |

Information:

For information about the relationship between the input on the module and the channel name, see section "reACTION function blocks - General".

Scaling the position encoder (rtiABRPos)

Name:

CfO_ScalingUnits_ABR1

CfO_ScalingIncrements_ABR1

An optional gear ratio can be configured using registers "Units" and "Increments". The dividend for scaling is defined in register "Units"; the divisor is defined in register "Increments".

| Data type | Value | Information |
|-----------|--------------------|--|
| UDINT | 0 to 4,294,967,295 | CfO_ScalingUnits_ABR1: Units per interval CfO_ScalingIncrements_ABR1: Increments per interval |

Formula for calculation

$$\text{Gear ratio} = \text{ScalingUnits} / \text{ScalingIncrements}$$
Example 1

ScalingUnits = 1

ScalingIncrements = 1

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 1/1$$

In this example, the ABR position value is output unchanged on output "Pos".

Example 2

ScalingUnits = 10

ScalingIncrements = 4

$$\text{Position value (Pos)} = \text{ABR increments} * \text{ScalingUnits} / \text{ScalingIncrements}$$

$$\text{Position value (Pos)} = \text{ABR increments} * 10/4$$

In this example, the ABR position value is multiplied by 2.5 and output on output "Pos".

Information:

The encoder values are calculated internally as INT64 values in 32.32 format. On output "Pos" of function block "rtiABRPos", only the whole number value (INT32) is output for the user. The fixed point decimal places are used internally to calculate a higher resolution.

9.28.7.11.10 Direct I/O configuration

This module is equipped with 8 digital channels, 1 analog input and 1 analog output. In the "Direct I/O" function model, behavior is based on that of a standard module. The I/O channels are managed by an extremely simplified reACTION program. The function model primarily serves to check that the I/O channels are functioning properly.

9.28.7.11.10.1 Direction of digital channels

Name:

CfO_DigitalDirection

This register determines the signal direction of digital channels 3, 4, 7 and 8.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-------------------------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | Direction - Digital channel 3 | 0 | Input |
| | | 1 | Output |
| 3 | Direction - Digital channel 4 | 0 | Input |
| | | 1 | Output |
| 4 - 5 | Reserved | 0 | |
| 6 | Direction - Digital channel 7 | 0 | Input |
| | | 1 | Output |
| 7 | Direction - Digital channel 8 | 0 | Input |
| | | 1 | Output |

9.28.7.11.10.2 Filtering digital channels

Name:

CfO_DigitalFilter

This register defines the filter time of the digital channels. The filter value affects both the switching delay as well as the immunity of the channels.

| Data type | Value |
|-----------|--------------------------|
| UDINT | 0 to 500000: Units 10 ns |

9.28.7.11.10.3 Filter of the analog input

Name:

CfO_AnalogFilter01

This register sets the filter level of the analog input.

| Data type | Value |
|-----------|--------|
| UDINT | 0 to 7 |

$$2^{\text{AnalogFilter}} = \text{FilterLevel} = \frac{\text{Out(ADC)}_t - \text{Out(Filter)}_{t-1}}{\text{Out(Filter)}_t - \text{Out(Filter)}_{t-1}} \cong \frac{\Delta\text{Out(ADC)}}{\Delta\text{Out(Filter)}}$$

The filter level results as the exponent to base 2 and corresponds to the ratio of the change of the digitalized input value to the change of the filtered analog value.

9.28.7.11.10.4 Limit values of the analog input

Name:

CfO_LowerLimit01

CfO_UpperLimit01

These registers define the upper and lower user-specific limit values for the analog input.

| Data type | Value |
|-----------|---|
| DINT | LowerLimit: -32767 to 32767 (default: -32767) |
| | UpperLimit: -32767 to 32767 (default: 32767) |

9.28.7.11.11 Direct I/O communication

This module is equipped with the following inputs and outputs:

- 4 digital inputs (sink) for 24 VDC
- 4 digital channels configurable as inputs (sink) or outputs (sink or source) for 24 VDC
- 1 analog input of type ± 10 V
- 1 analog output of type ± 10 V

9.28.7.11.11.1 Digital outputs

Name:

DigitalOutput03

DigitalOutput04

DigitalOutput07

DigitalOutput08

This register is used to predefine the value that should be output on the digital output.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------|-------|-------------|
| 0 - 1 | Reserved | 0 | |
| 2 | DigitalOutput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalOutput04 | 0 | FALSE |
| | | 1 | TRUE |
| 4 - 5 | Reserved | 0 | |
| 6 | DigitalOutput07 | 0 | FALSE |
| | | 1 | TRUE |
| 7 | DigitalOutput08 | 0 | FALSE |
| | | 1 | TRUE |

9.28.7.11.11.2 Digital inputs

Name:

DigitalInput01

DigitalInput02

DigitalInput03

DigitalInput04

DigitalInput05

DigitalInput06

DigitalInput07

DigitalInput08

This register indicates the value read for the respective digital input.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------|-------|-------------|
| 0 | DigitalInput01 | 0 | FALSE |
| | | 1 | TRUE |
| 1 | DigitalInput02 | 0 | FALSE |
| | | 1 | TRUE |
| 2 | DigitalInput03 | 0 | FALSE |
| | | 1 | TRUE |
| 3 | DigitalInput04 | 0 | FALSE |
| | | 1 | TRUE |

9.28.7.11.11.3 Analog input

Name:

AnalogInput01

The analog input value is mapped in this register.

| Data type | Value |
|-----------|-----------------|
| INT | -32767 to 32767 |

9.28.7.11.11.4 Analog output

Name:

AnalogOutput01

This register defines the value for the analog output.

| Data type | Values |
|-----------|-----------------|
| INT | -32767 to 32767 |

9.28.7.11.12 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.28.7.11.13 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 200 μ s |

9.29 Redundancy system

Redundant network cabling is often essential to safe operation, especially in processing plants. The potential for danger, especially to the lines that run through the plant, can be disproportionately high in relation to the need to keep communication active in all operating situations. Redundant cabling and separate cable routing are effective ways to help reduce this risk.

POWERLINK cable redundancy is based on the principle of doubling the communication lines as well as providing continuous and simultaneous monitoring. A mechanism feeds data simultaneously into two cable lines. The same mechanisms are used to receive this data from the redundant network.

The following modules can be used to set up a POWERLINK network with cable redundancy:

- X20IF2181-2 interface module
- X20HB8884 compact link selector
- X20BC8084 bus controller

9.29.1 Summary

| Model number | Short description | Page |
|--------------|--|------|
| X20HB8884 | X20 compact link selector, 2x RJ45, order bus base, power supply module and terminal block separately. | 3614 |
| X20cHB8884 | X20 compact link selector, coated, 2x RJ45, order bus base, power supply module and terminal block separately. | 3614 |

9.29.2 X20(c)HB8884

Data sheet version: 2.24

9.29.2.1 General information

POWERLINK is a standard protocol for Fast Ethernet with hard real-time properties. The Ethernet POWERLINK Standardization Group (EPSSG) ensures that the standard remains open and is continually developed. www.ether-net-powerlink.org

Systems with redundant cabling can be implemented easily using POWERLINK. Unlike ring redundancy, cable redundancy does not require cable looping, which can sometimes be problematic. This allows the creation of all types of tree structures. When using a device with the link selector function, data is always transferred via the highest quality network lines. The link selector function is integrated in the module compact link selector. This makes it easy to connect any POWERLINK device to a redundant POWERLINK network.

- Connecting POWERLINK devices to the POWERLINK cable redundancy system
- Integrated compact link selector function

9.29.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.29.2.2.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.29.2.3 Order data

| Model number | Short description | Figure |

1) Spacing is based on the width of bus base X20BB81 or X20BB82. 1 X20HB2880 hub expansion module or 2 X20HB2885 hub expansion modules and 1 X20PS8002 power supply module are also always required for the compact link selector.

9.29.2.5 Operating and connection elements

9.29.2.5.1 LED status indicators

| Figure | LED | Color | Status | Description |
|--------|-------------------|-------|--------------|--|
| | S/E ¹⁾ | Green | On | An active POWERLINK network was detected on both networks. |
| | | Red | Single flash | Network 2 is active. Disturbances detected on network 1 or there is no POWERLINK network active. |
| | | Red | Double flash | Network 1 is active. Disturbances detected on network 2 or there is no POWERLINK network active. |
| | | Red | On | Failure of both networks. |
| | L/A IFx | Green | Blinking | A link to the peer station has been established. The LED blinks when Ethernet activity is taking place on the bus. |
| | | | On | A link to the remote station has been established. |

1) The Status/Error LED is a green/red dual LED.

9.29.2.5.2 POWERLINK node numbers

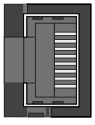

The number switches have no function during operation. They are only used for product testing.

9.29.2.5.3 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see "Cabling guidelines for X20 modules with an Ethernet cable" on page 58.

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.29.2.6 POWERLINK cable redundancy system

It is often indispensable to have redundant network cabling, especially in systems that handle technical processes. The potential for danger, especially to the lines that run through the system, is disproportionately high in relation to the need to keep communication active in all operating situations. This risk is effectively reduced with double cabling that is routed separately.

The POWERLINK cable redundancy system is based on the principle of doubling the transfer routing as well as providing continual and simultaneous monitoring. That means data is simultaneously fed into two cable lines using a corresponding mechanism. The same mechanisms are used to receive these telegrams from the redundant network.

Information:

Details about the structure of a redundancy system can be found in the "Redundancy for control systems" user's manual. The user's manual is available in the Downloads section of the B&R website www.br-automation.com.

9.30 System modules for the X20 hub system

The X20 hub system has a modular structure. In addition to the basis modules, the following system modules are also required,

- Bus base
- Hub expansion module(s)
- Power supply module for standalone hub

9.30.1 Summary

| Model number | Short description | Page |
|--------------|--|------|
| X20HB1881 | X20 hub expansion module, integrated 1-port hub, for multimode fiber optic cable | 3619 |
| X20HB1882 | X20 hub expansion module, integrated 1-port hub, for monomode fiber optic cables | 3623 |
| X20HB2880 | X20 hub expansion module, integrated 2-port hub, 2x RJ45 | 3627 |
| X20HB2881 | X20 hub expansion module, integrated 2-port hub, for fiber optic cable | 3632 |
| X20PS8002 | X20 power supply module for standalone hub and compact link selector | 3636 |
| X20cHB1881 | X20 hub expansion module, coated, integrated 1-port hub, for fiber optic cable | 3619 |
| X20cHB2880 | X20 hub expansion module, coated, integrated 2-port hub, 2x RJ45 | 3627 |
| X20cHB2881 | X20 hub expansion module, coated, integrated 2-port hub, for fiber optic cable | 3632 |
| X20cPS8002 | X20 power supply module, coated, for standalone hub and compact link selector | 3636 |

9.30.2 X20(c)HB1881

Data sheet version: 1.41

9.30.2.1 General information

The POWERLINK bus controllers X20BC8083, X20BC8084 (revision D0 or higher) and the stand-alone hub X20H-B8880 are equipped with a modular hub expansion. An additional 1 or 2 slots are available, depending on the bus base used. The X20HB1881 hub expansion module can be operated in these slots. Note that the hardware revision of the X20BC8083 and the X20HB8880 must be \geq F0.

The hub expansion module is a 1x hub. The Ethernet connection is made using 62.5/125 μ m or 50/125 μ m fiber optic multimode cable with a duplex LC connection. The module and network status is indicated using LEDs.

- Hub expansion module
- 1x hub 100 BASE-FX
- Hot-swap-capable

Information:

This module is not suitable for POWERLINK ring redundancy applications.

9.30.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

| Figure | Description |
|--------|------------------------------|
| | 100BASE-FX, female duplex LC |

9.30.2.5.2.1 Wiring guidelines for X20 modules with fiber optic cable

The following wiring guidelines must be observed:

- Cable fiber type: Multimode fiber with 62.5/125 µm or 50/125 µm core diameter
- On both sides: Duplex LC male connector
- Observe minimum cable flex radius (see data sheet for the cable)

9.30.2.6 Network size and collision detection

Information:

This section applies to the use of Ethernet networks, not POWERLINK networks.

According to Ethernet specification IEEE 802.3, the transmission duration of a frame of minimum length must always be greater than the round-trip delay time (RTD). RTD is the time needed by a data packet to travel from one end of the network to the other.

If this is not observed, collision detection can no longer be guaranteed.

Illustration of RTD

When using fiber optic cables, the default maximum size is 175 m. Since there are often different devices in a network using different PHYs, the propagation delay of the frames changes since each PHY has different latency. This also affects the network size, and collision detection can no longer be guaranteed at 175 m.

For this reason, it is necessary to re-check whether the transmission duration of a frame of minimum length is actually greater than the maximum RTD.

Example for calculating network size

- Transfer rate: 100 Mbit/s
- Length of the fiber optic cable: 175 m
- Number of hubs: 2
- Hub propagation delay of a frame: 1 μ s
- Minimum frame size in the Ethernet network: 72 bytes

Calculation procedure

| | |
|--|--|
| 1. How long does 1 byte need at 100 Mbit/s – 100 Mbit/s / 8 = 12.5 MB/s | $\frac{12,500,000}{1} = \frac{1}{x}$ $x = \frac{1s}{12,500,000} = 80ns$ |
| 2. Propagation delay of minimum Ethernet frame – Minimum frame in Ethernet network: 72 bytes | $72 * 80ns = 5.76\mu s$ |
| 3. Propagation delay in cable and hub (100 m cable = 0.5 μ s) – 175 m cable = 1.75 x 0.5 μ s – 2 hubs = 2 x 1 μ s | $\frac{175}{100}m * 0.5\mu s + 2\mu s = 2.875\mu s$ |
| 4. Calculation of total propagation delay – Outbound/Inbound propagation delay | $2.875\mu s * 2 = 5.75\mu s$ |

Result

Collision detection is possible since the total time of 5.75 μ s is less than the minimum Ethernet propagation delay of 5.76 μ s.

With a longer cable or device with different latency, collision detection would no longer exist.

9.30.3 X20HB1882

Data sheet version: 1.03

9.30.3.1 General information

POWERLINK bus controllers X20BC8083 and X20BC8084 (revision D0 and later) and standalone hub X20HB8880 are equipped with a modular hub expansion. An additional 1 or 2 slots are available depending on the bus base being used. Hub expansion module X20HB1882 can be operated in these slots. Note that the hardware revision of the X20BC8083 and X20HB8880 must be \geq F0.

The hub expansion module is designed as a 1-port hub. The Ethernet connection is made using 9/125 μ m single-mode glass fiber cables with a duplex LC connector. The module state and network status are indicated using LEDs.

- Hub expansion module
- 1-port hub, 100BASE-FX
- Single-mode glass fiber cables
- Range up to 50 km
- Hot-swappable

Information:

This module is not suitable for POWERLINK ring redundancy applications.

9.30.3.4.2.1 Cabling guidelines for X20 modules with fiber optic cables

The following cabling guidelines must be observed:

- Cable fiber type: Single-mode fiber with 9/125 μm core diameter
- On both sides: Male duplex LC connector
- Observe the minimum cable bend radius (see data sheet for the cable).

9.30.3.5 Network size and collision detection

Information:

This section applies to the use of Ethernet networks, not POWERLINK networks.

According to Ethernet specification IEEE 802.3, the transmission duration of a frame of minimum length must always be greater than the round-trip delay time (RTD). RTD is the time needed by a data packet to travel from one end of the network to the other.

If this is not observed, collision detection can no longer be guaranteed.

Illustration of RTD

When using fiber optic cables, the default maximum size is 175 m. Since there are often different devices in a network using different PHYs, the propagation delay of the frames changes since each PHY has different latency. This also affects the network size, and collision detection can no longer be guaranteed at 175 m.

For this reason, it is necessary to re-check whether the transmission duration of a frame of minimum length is actually greater than the maximum RTD.

Example for calculating network size

- Transfer rate: 100 Mbit/s
- Length of the fiber optic cable: 175 m
- Number of hubs: 2
- Hub propagation delay of a frame: 1 μ s
- Minimum frame size in the Ethernet network: 72 bytes

Calculation procedure

| | |
|--|--|
| 1. How long does 1 byte need at 100 Mbit/s – 100 Mbit/s / 8 = 12.5 MB/s | $\frac{12,500,000}{1} = \frac{1}{x}$ $x = \frac{1s}{12,500,000} = 80ns$ |
| 2. Propagation delay of minimum Ethernet frame – Minimum frame in Ethernet network: 72 bytes | $72 * 80ns = 5.76\mu s$ |
| 3. Propagation delay in cable and hub (100 m cable = 0.5 μ s) – 175 m cable = 1.75 x 0.5 μ s – 2 hubs = 2 x 1 μ s | $\frac{175}{100}m * 0.5\mu s + 2\mu s = 2.875\mu s$ |
| 4. Calculation of total propagation delay – Outbound/Inbound propagation delay | $2.875\mu s * 2 = 5.75\mu s$ |

Result

Collision detection is possible since the total time of 5.75 μ s is less than the minimum Ethernet propagation delay of 5.76 μ s.

With a longer cable or device with different latency, collision detection would no longer exist.

9.30.4 X20(c)HB2880

Data sheet version: 2.42

9.30.4.1 General information

The POWERLINK bus controller X20BC8083 and the stand-alone hubs X20HB8880 and X20HB8815 are equipped with a modular hub expansion. An additional 1 or 2 slots are available, depending on the bus base used. The X20HB2880 hub expansion module can be operated in these slots.

The status of the module and network are indicated by LEDs.

- Hub expansion module
- 2x hub 100 BASE-TX

9.30.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.30.4.2.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.30.4.8 Network size and collision detection

Information:

This section applies to the use of Ethernet networks, not POWERLINK networks.

According to Ethernet specification IEEE 802.3, the transmission duration of a frame of minimum length must always be greater than the round-trip delay time (RTD). RTD is the time needed by a data packet to travel from one end of the network to the other.

If this is not observed, collision detection can no longer be guaranteed.

Illustration of RTD

When using copper cables, the maximum distance is generally 100 m. Since there are often many different devices with different PHYs in a network, the propagation delay of the frames changes due to the different latency of each PHY. This also affects the network size, and collision detection can no longer be guaranteed at 100 m.

Example for calculating network size

The following parameters are specified for a network:

- Transfer rate: 100 Mbit/s
- Cable length: 100 m
- Number of hubs: 2
- Hub propagation delay of a frame: 1 μ s
- Minimum frame size in the Ethernet network: 72 bytes

Calculation procedure

| | |
|--|---|
| 1. How long does 1 byte take at 100 Mbit/s – 100 Mbit/s / 8 = 12.5 MB/s | $\frac{12,500,000}{1} = \frac{1}{x}$ $x = \frac{1\text{s}}{12,500,000} = 80\text{ns}$ |
| 2. Propagation delay of minimum Ethernet frame – Minimum frame in Ethernet network: 72 bytes | $72 * 80\text{ns} = 5.76\mu\text{s}$ |
| 3. Propagation delay in cable and hub – 100 m cable = 0.5 μ s – 2 hubs = 2 x 1 μ s | $2\mu\text{s} + 0.5\mu\text{s} = 2.5\mu\text{s}$ |
| 4. Calculation of total propagation delay – Outbound/Inbound propagation delay | $2.5\mu\text{s} * 2 = 5\mu\text{s}$ |

Result

Collision detection is possible since the total time of 5 μ s is less than the minimum Ethernet propagation delay of 5.76 μ s.

Example for calculating the network reach with devices between 2 stations

Corresponding to the previous example, the following situation occurs in a network with 3 hubs and 100 m cables:

- The transmission duration of a frame of minimum length is 5.76 μ s.

Calculation procedure

| | |
|--|--|
| 1. Propagation delay in cable and hub – 100 m cable = 0.5 μ s – 3 hubs = 3 x 1 μ s | $3\mu\text{s} + 0.5\mu\text{s} = 3.5\mu\text{s}$ |
| 2. Calculation of total propagation delay – Outbound/Inbound propagation delay | $3.5\mu\text{s} * 2 = 7\mu\text{s}$ |

Result

Collision detection is not possible since the total time of 7 μ s is greater than the minimum Ethernet propagation delay of 5.76 μ s.

The ≈ 1.3 μ s missing for collision detection can only be recovered by removing a hub.

9.30.5 X20(c)HB2881

Data sheet version: 1.41

9.30.5.1 General information

The POWERLINK bus controller X20BC8083 and the stand-alone hubs X20HB8880 and X20HB8815 are equipped with a modular hub expansion. An additional 1 or 2 slots are available, depending on the bus base used. The X20HB2881 hub expansion module can be operated in these slots. Note that the hardware revision of the X20BC8083 and the X20HB8880 must be $\geq F0$.

The hub expansion module is a 2x hub. The Ethernet connection is made using 62.5/125 μm or 50/125 μm fiber optic multimode cable with a duplex LC connection. The status of the module and network are indicated by LEDs.

- Hub expansion module
- 2x Hub 100 BASE-FX

Information:

This module is not suitable for POWERLINK ring redundancy applications.

9.30.5.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.30.5.5.2.1 Wiring guidelines for X20 modules with fiber optic cable

The following wiring guidelines must be observed:

- Cable fiber type: Multimode fiber with 62.5/125 μm or 50/125 μm core diameter
- On both sides: Duplex LC male connector
- Observe minimum cable flex radius (see data sheet for the cable)

9.30.5.6 Network size and collision detection

Information:

This section applies to the use of Ethernet networks, not POWERLINK networks.

According to Ethernet specification IEEE 802.3, the transmission duration of a frame of minimum length must always be greater than the round-trip delay time (RTD). RTD is the time needed by a data packet to travel from one end of the network to the other.

If this is not observed, collision detection can no longer be guaranteed.

Illustration of RTD

When using fiber optic cables, the default maximum size is 175 m. Since there are often different devices in a network using different PHYs, the propagation delay of the frames changes since each PHY has different latency. This also affects the network size, and collision detection can no longer be guaranteed at 175 m.

For this reason, it is necessary to re-check whether the transmission duration of a frame of minimum length is actually greater than the maximum RTD.

Example for calculating network size

- Transfer rate: 100 Mbit/s
- Length of the fiber optic cable: 175 m
- Number of hubs: 2
- Hub propagation delay of a frame: 1 μ s
- Minimum frame size in the Ethernet network: 72 bytes

Calculation procedure

| | |
|--|--|
| 1. How long does 1 byte need at 100 Mbit/s – 100 Mbit/s / 8 = 12.5 MB/s | $\frac{12,500,000}{1} = \frac{1}{x}$ $x = \frac{1s}{12,500,000} = 80ns$ |
| 2. Propagation delay of minimum Ethernet frame – Minimum frame in Ethernet network: 72 bytes | $72 * 80ns = 5.76\mu s$ |
| 3. Propagation delay in cable and hub (100 m cable = 0.5 μ s) – 175 m cable = 1.75 x 0.5 μ s – 2 hubs = 2 x 1 μ s | $\frac{175}{100}m * 0.5\mu s + 2\mu s = 2.875\mu s$ |
| 4. Calculation of total propagation delay – Outbound/Inbound propagation delay | $2.875\mu s * 2 = 5.75\mu s$ |

Result

Collision detection is possible since the total time of 5.75 μ s is less than the minimum Ethernet propagation delay of 5.76 μ s.

With a longer cable or device with different latency, collision detection would no longer exist.

9.30.6 X20(c)PS8002

Data sheet version: 2.35

9.30.6.1 General information

The supply module is used to supply X20 stand-alone devices. These include e.g. the X20HB8884 POWERLINK compact link selector and the X20HB8880 stand alone hub.

- Supply for X20 stand-alone devices
- No electrical isolation between the I/O supply and the device power supply

9.30.6.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.30.6.2.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

The rated output current for the supply is 7 W. Derating must be taken into consideration based on mounting orientation.

9.31 System modules for the X20 redundancy system

The X20 redundancy system has a modular structure. In addition to the basis modules, the following system modules are also required,

- Bus base
- Hub expansion module(s)
- Power supply module for standalone hub

9.31.1 Summary

| Model number | Short description | Page |
|--------------|--|------|
| X20HB2885 | X20 hub expansion module, integrated active 2-port hub, 2x RJ45 | 3641 |
| X20HB2886 | X20 hub expansion module, integrated active 2-port hub, 2 fiber optic interfaces | 3644 |
| X20cHB2885 | X20 hub expansion module, coated, integrated active 2-port hub, 2x RJ45 | 3641 |
| X20cHB2886 | X20 hub expansion module, coated, integrated active 2-port hub, 2 fiber optic interfaces | 3644 |

9.31.2 X20(c)HB2885

Data sheet version: 2.34

9.31.2.1 General information

The X20BC8084 POWERLINK bus controller and the X20HB8884 module are equipped with an integrated link selector function. An additional 1 or 2 slots are available, depending on the bus base used. The active X20HB2885 hub expansion module can be operated in these slots.

The active hub expansion module is equipped with one integrated 2x hub and allows redundant wiring. This means that the connection between the two ports remains intact if there is a failure in the bus controller or Compact Link Selector. The status of the module and network are indicated by LEDs.

- Active hub expansion module
- 2x Fast Ethernet hub for redundant wiring
- Hot-swap-capable

9.31.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.31.2.3 Order data

| Model number | Short description | Figure |

9.31.3 X20(c)HB2886

Data sheet version: 1.31

9.31.3.1 General information

The X20BC8084 POWERLINK bus controller and the X20HB8884 module are equipped with an integrated link selector function. An additional 1 or 2 slots are available, depending on the bus base used. The active X20HB2886 hub expansion module can be operated in these slots. Note that the hardware revision of the X20BC8084 and the X20HB8884 must be $\geq E0$.

The active hub expansion module is equipped with one integrated 2x hub and allows redundant wiring. This means that the connection between the two 100 Base-FX interfaces remains intact if there is a failure in the bus controller or Compact Link Selector. The Ethernet connection is made using 62.5/125 μm or 50/125 μm fiber optic multimode cable with a duplex LC connection. The status of the module and network are indicated by LEDs.

- Active hub expansion module
- 2x 100 BASE-FX hub for redundant wiring
- Hot-swap-capable

9.31.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

| Figure | Description |
|---|-------------------------------|
| <p>Duplex LC (IF1) Tx Rx</p> <p>Duplex LC (IF2) Tx Rx</p> | 100 BASE-FX, Duplex LC female |

9.31.3.5.2.1 Wiring guidelines for X20 modules with fiber optic cable

The following wiring guidelines must be observed:

- Cable fiber type: Multimode fiber with 62.5/125 µm or 50/125 µm core diameter
- On both sides: Duplex LC male connector
- Observe minimum cable flex radius (see data sheet for the cable)

9.32 Temperature modules

Temperature measurement values are converted into number values which can be processed by the PLC using temperature modules.

In the PLC, the number values are always in 16-bit 2s complement, regardless of the resolution. In this way, the resolution (number of steps) of the temperature module does not have to be considered when creating the application program.

For temperature measurements, the temperature module returns the measured value in 0.1°C steps. That means, a result of 750 corresponds to 75.0°C. The data format 0.1°C is supported as standard by all temperature modules.

Every channel on temperature module has a status LED.

Measurement methods

Depending on the area to be measured, there are two different methods for determining the temperature.

Method 1: Direct measurement using measurement resistor

The temperature module measures an electrical value that makes it possible to directly infer the current absolute temperature.

A measurement resistor often used in this method is the PT1000. Measuring the electrical resistance can be used to determine the absolute temperature at the measurement point for a temperature range of approximately -200°C to 850°C.

Method 2: Indirect measurement using thermocouples

Thermocouples are primarily used whenever it is not possible to use measurement resistors, for example because the environment directly around the measurement point contains aggressive gases.

This method of measuring bears on the basics of the thermoelectric effect. The module measures an electrical voltage, which can then be used to derive the difference in temperature.

Thermocouple modules from B&R prepare the temperature value at the measurement point as an absolute value. The measured temperature difference is referenced against another temperature that is usually measured directly at another location (see method 1).

Information:

In the best case, the temperature at the location where the thermocouple crosses an inexpensive copper cable is used as the reference or compensation value.

9.32.1 Summary

| Model number | Short description | Page |
|--------------|--|------|
| X20AT2222 | X20 temperature input module, 2 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections | 3649 |

9.32.2 X20AT2222

Data sheet version: 3.19

9.32.2.1 General information

The module is equipped with 2 inputs for PT100/PT1000 resistance temperature measurement.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 inputs for resistance temperature measurement
- For PT100 and PT1000
- Configurable sensor type per channel
- Direct resistance measurement
- Configurable 2- or 3- wire connections per module
- Configurable filter time

Table 636: X20AT2222 - Technical data

- 1) Based on the current resistance value.
- 2) Based on the entire resistance measurement range.

9.32.2.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

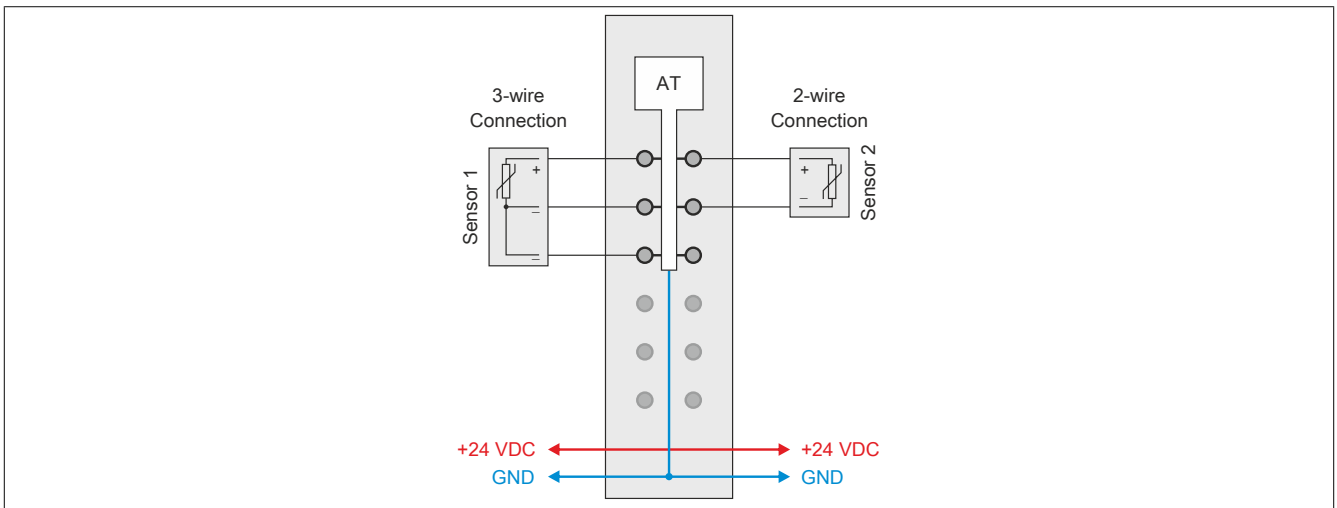

| Figure | LED | Color | Status | Description |
|---|-------|-----------------------------|--|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Single flash | Warning/Error on an I/O channel. Overflow or underflow of the analog inputs. |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1 - 2 | Green | Off | The input is switched off |
| | | | Blinking | Overflow, underflow or open line |
| On | | | Analog/digital converter running, value OK | |

9.32.2.5 Pinout

Channels that are not being used should be disabled.

9.32.2.7 Input circuit diagram

2-wire connections

3-wire connections

9.32.2.8 Register description

9.32.2.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.32.2.8.2 Function model 0 - "3-wire connections" and function model 1 - "2-wire connections"

For this module, the connection type is selected using function models 0 and 1.

| Function model | Connection type |
|----------------|-------------------------------|
| 0 | 3-wire connections (standard) |
| 1 | 2-wire connections |

The registers used are identical for both function models:

| Register | Name | Data type | Read | | Write | |
|----------------------|---|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |
| 16 | ConfigOutput01 (Input filter) | USINT | | | | • |
| 18 | ConfigOutput02 (Sensor configuration) | USINT | | | | • |
| Communication | | | | | | |
| 0 | Temperature01 | INT | • | | | |
| | Resistor01 | UINT | | | | |
| 2 | Temperature02 | INT | • | | | |
| | Resistor02 | UINT | | | | |
| 28 | IOCycleCounter | USINT | • | | | |
| 30 | StatusInput01 | USINT | • | | | |

9.32.2.8.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------------------|----------------------|---|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | | |
| 16 | - | ConfigOutput01 (Input filter) | USINT | | | | • |
| 18 | - | ConfigOutput02 (Sensor configuration) | USINT | | | | • |
| Communication | | | | | | | |
| 0 | 0 | Temperature01 | INT | • | | | |
| | 0 | Resistor01 | UINT | | | | |
| 2 | 2 | Temperature02 | INT | • | | | |
| | 2 | Resistor02 | UINT | | | | |
| 28 | - | IOCycleCounter | USINT | | • | | |
| 30 | - | StatusInput01 | USINT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.32.2.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.32.2.8.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.32.2.8.4 General information

9.32.2.8.4.1 Analog inputs

The module outputs the converted analog values to the registers. Other ranges of values or data types result depending on resistance or temperature measurement.

Information:

Operating channels outside specifications can affect neighboring channels.

9.32.2.8.4.2 Timing

The timing for acquiring measured values is controlled by the converter hardware. All switched-on inputs are converted during each conversion cycle and transferred halfway through the X2X Link cycle.

9.32.2.8.4.3 Conversion time

The conversion time for the channels depends on their use. For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

| Use of the channels | Conversion time |
|--|--|
| 1 channel | 1 · Filter time |
| n channels with the same sensor type | $n \cdot (20 \text{ ms} + \text{Filter time})$ |
| n channels with different sensor types | $n \cdot (20 \text{ ms} + 2 \cdot \text{Filter time})$ |

9.32.2.8.4.4 Reduced update time

Any inputs that are not needed can be switched off, which reduces the I/O update time. Inputs can also be only switched off temporarily.

The time saved corresponds to the following:

$$\text{Time saved} = 2 \cdot 20 \text{ ms} + \text{Filter time}$$

The conversion time for the remaining channel corresponds to the filter time.

Examples

Inputs are filtered using a 60 Hz filter.

| | Example 1 | Example 2 |
|--------------------|-----------|-----------|
| Switched on inputs | 1 | 1 to 2 |
| Conversion time | 16.7 ms | 73.4 ms |

9.32.2.8.5 Configuration

9.32.2.8.5.1 Input filter

Name:

ConfigOutput01

The filter time of all analog inputs is defined in this register.

| Data type | Value | Filter | Filter time |
|-----------|-------|--|-------------|
| USINT | 0 | 15 Hz | 66.7 ms |
| | 1 | 25 Hz | 40 ms |
| | 2 | 30 Hz | 33.3 ms |
| | 3 | 50 Hz (bus controller default setting) | 20 ms |
| | 4 | 60 Hz | 16.7 ms |
| | 5 | 100 Hz | 10 ms |
| | 6 | 500 Hz | 2 ms |
| | 7 | 1000 Hz | 1 ms |

9.32.2.8.5.2 Sensor configuration

Name:

ConfigOutput02

This register can be used to configure the sensor type for individual channels.

This module is designed for temperature and resistance measurement. The sensor type must be specified because of the different calibration values for temperature and resistance.

The default setting for all channels is ON. To save time, individual channels can be switched off (see "[Reduced update time](#)" on page 3655).

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| USINT | See bit structure. | 34 |

Bit structure:

| Bit | Name | Value | Information | | |
|-------------|--|-------------|--|-------------|--|
| 0 - 3 | Channel 1 | 0000 - 0001 | Reserved | | |
| | | 0010 | Sensor type PT100 (bus controller default setting) | | |
| | | 0011 | PT1000 sensor type | | |
| | | 0100 | Reserved (channel switched off) | | |
| | | 0101 | Resistance measurement 0.1 to 4500 Ω | | |
| | | 0110 | Resistance measurement 0.05 to 2250 Ω | | |
| | | 0111 | Channel switched off | | |
| | | 1000 - 1111 | Reserved | | |
| | | 4 - 7 | Channel 2 | 0000 - 0001 | Reserved |
| | | | | 0010 | Sensor type PT100 (bus controller default setting) |
| 0011 | PT1000 sensor type | | | | |
| 0100 | Reserved (channel switched off) | | | | |
| 0101 | Resistance measurement 0.1 to 4500 Ω | | | | |
| 0110 | Resistance measurement 0.05 to 2250 Ω | | | | |
| 0111 | Channel switched off | | | | |
| 1000 - 1111 | Reserved | | | | |

9.32.2.8.6 Communication

9.32.2.8.6.1 Input values of analog inputs

Name:

Temperature01 to Temperature02

Resistor01 to Resistor02

This register contains the analog input values depending on the configured operating mode.

| Data type | Digital value | Input signal |
|-----------|---------------------------------------|---------------------------------------|
| INT | -2000 to 8500 (for -200.0 to 850.0°C) | PT100 sensor type |
| | -2000 to 8500 (for -200.0 to 850.0°C) | PT1000 sensor type |
| UINT | 1 to 45000 (resolution 0.1 Ω) | Resistance measurement 0.1 to 4500 Ω |
| | 1 to 45000 (resolution 0.05 Ω) | Resistance measurement 0.05 to 2250 Ω |

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the operating mode until the first conversion:
 - From "Resistance measurement" to "Sensor type PTxx": 0x8000
 - From "Sensor type PTxx" to "Resistance measurement": 0xFFFF
- If the input is not switched on, 0x8000 is output.

9.32.2.8.6.2 I/O cycle counter

Name:

IOCycleCounter

The cyclic counter increases after all input data has been updated.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Repeating counter |

9.32.2.8.6.3 Input status

Name:

StatusInput01

The module's inputs are monitored. A change in the monitoring status generates an error message.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|----------------------------|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Lower limit value exceeded |
| | | 10 | Upper limit value exceeded |
| | | 11 | Open line |
| 2 - 3 | Channel 2 | 00 | No error |
| | | 01 | Lower limit value exceeded |
| | | 10 | Upper limit value exceeded |
| | | 11 | Open line |
| 4 - 7 | | 0 | |

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs.

| Error status | Temperature measurement Digital value for error | Resistance measurement Digital value for error |
|----------------------------|---|---|
| Open line | 32767 (0x7FFF) | 65535 (0xFFFF) |
| Upper limit value exceeded | 32767 (0x7FFF) | 65535 (0xFFFF) |
| Lower limit value exceeded | -32767 (0x8001) | 0 (0x0000) |
| Invalid value | -32768 (0x8000) ¹⁾ 32767 (0x7FFF) ²⁾ 65535 (0xFFFF) ³⁾ | 65535 (0xFFFF) |

- 1) Default value or channel was disabled in the I/O configuration.
- 2) After switching off the channel during operation.
- 3) Value in function model 254 - Bus controller.

9.32.2.8.7 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|--------------------|--|
| 100 μ s | |

9.32.2.8.8 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|-------------------------|--|
| 1 input | Equal to the filter time |
| 2 inputs | $2 \cdot 20 \text{ ms} + \text{filter time}$ |

9.32.3 X20(c)AT2311

Data sheet version: 3.20

9.32.3.1 General information

The module is equipped with 2 inputs for PT100 4-line resistance temperature measurement.

- 2 inputs for resistance temperature measurement
- PT100 sensor
- Direct resistance measurement
- 4-wire measurement
- Configurable filter time

9.32.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.32.3.3 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | Temperature measurement |  |
| X20AT2311 | X20 temperature input module, 2 resistance measurement inputs, PT100, resolution 0.001°C, 4-wire connections | |

Table 638: X20AT2311, X20cAT2311 - Technical data

- 1) To ensure accuracy, dummy module ZF0000 must be connected to the left and right of module AT2311.
- 2) Based on the current resistance value.
- 3) Based on the entire resistance measurement range.

9.32.3.5 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-----------------------------|------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Single flash | Warning/Error on an I/O channel. Overflow or underflow of the analog inputs. |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1 - 2 | Green | Off | The input is switched off |
| | | | Blinking | Overflow, underflow or open line |
| | | | On | Analog/digital converter running, value OK |

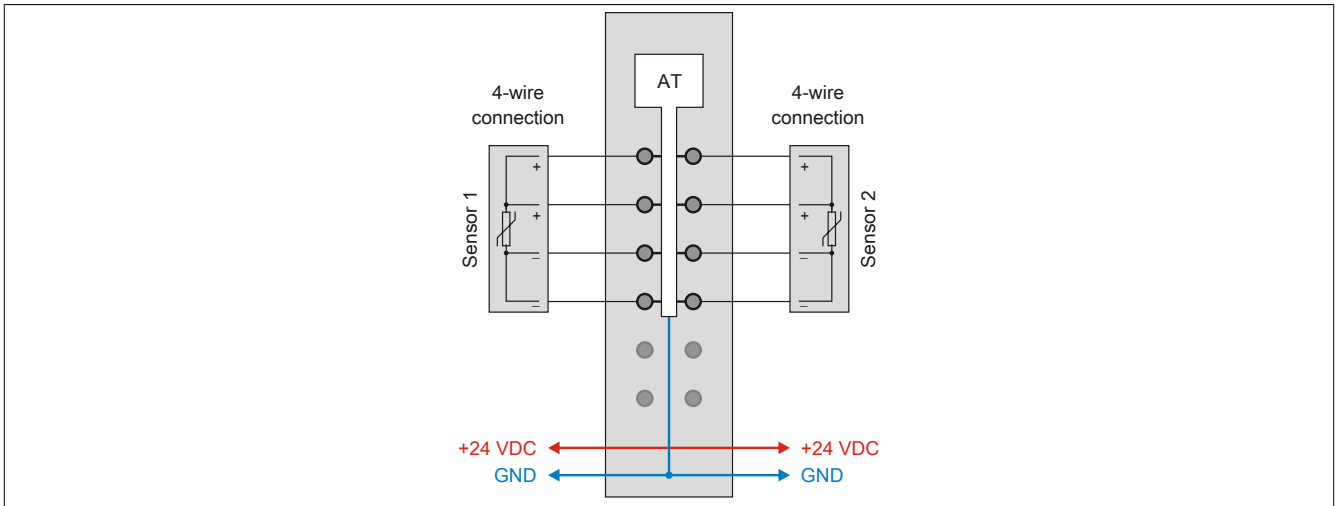

- 1) Depending on the configuration, a firmware update can take up to several minutes.

9.32.3.6 Pinout

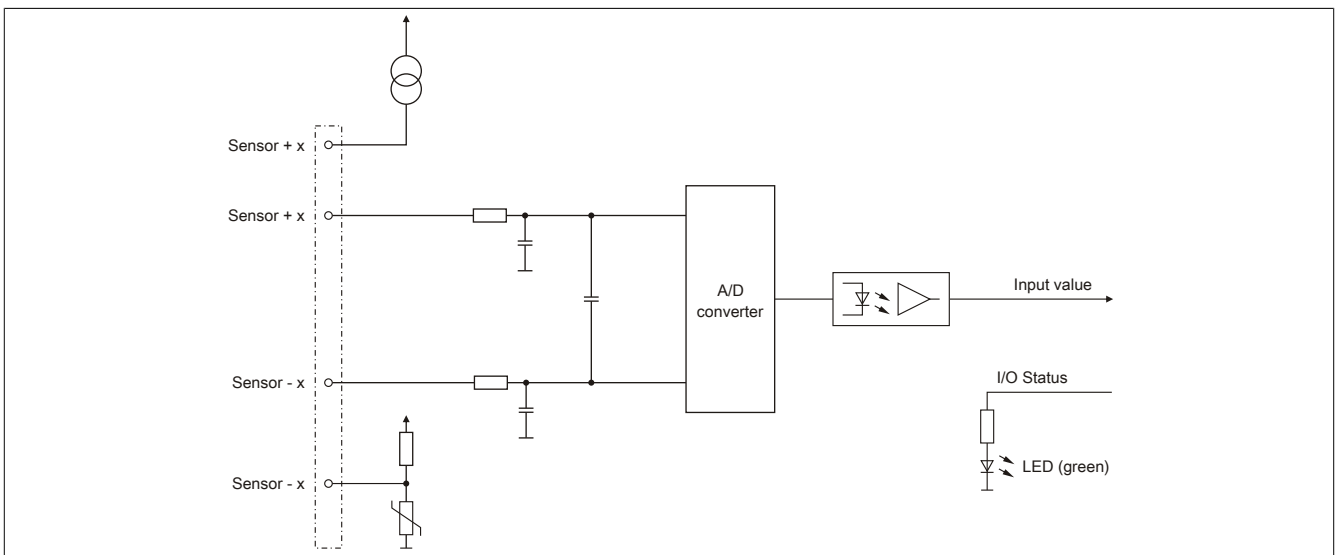

9.32.3.7 Connection example

To ensure accuracy, a ZF dummy module must be inserted on the left and right of the module.

9.32.3.8 Input circuit diagram

9.32.3.9 Register description

9.32.3.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.32.3.9.2 Function model 0 - Standard

| Register | Name | Data type | Read | | Write | |
|----------------------|--|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |
| 2049 | ConfigOutput01 (input filter) | USINT | | | | • |
| 2051 | ConfigOutput02 (sensor type and channel disabling) | USINT | | | | • |
| Communication | | | | | | |
| 2308 | Temperature01 | DINT | • | | | |
| | Resistor01 | UDINT | | | | |
| 2316 | Temperature02 | DINT | • | | | |
| | Resistor02 | UDINT | | | | |
| 2337 | IOCycleCounter | USINT | • | | | |
| 2345 | StatusInput01 | USINT | • | | | |

9.32.3.9.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------------------|----------------------|--|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | | |
| 2049 | - | ConfigOutput01 (input filter) | USINT | | | | • |
| 2051 | - | ConfigOutput02 (sensor type and channel disabling) | USINT | | | | • |
| Communication | | | | | | | |
| 0 | 0 | Temperature01 | DINT | • | | | |
| | | Resistor01 | UDINT | | | | |
| 4 | 4 | Temperature02 | DINT | • | | | |
| | | Resistor02 | UDINT | | | | |
| 2337 | - | IOCycleCounter | USINT | | • | | |
| 2345 | - | StatusInput01 | USINT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.32.3.9.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.32.3.9.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.32.3.9.4 General information

9.32.3.9.4.1 Timing

The timing for acquiring measured values is controlled by the converter hardware. All switched-on inputs are converted during each conversion cycle and transferred halfway through the X2X Link cycle.

9.32.3.9.4.2 Conversion time

The conversion time for the channels depends on the filter time configured in the "ConfigOutput1" on page 3664 register.

| Channel uses | Conversion time |
|---|-----------------|
| All channels independent of the configuration | 1x filter time |

9.32.3.9.4.3 Ratio of filter time to resolution

The following table shows the maximum frequency with which the specified resolution can be achieved.

| Filter / Filter time | Resolution |
|----------------------|------------|
| 5 Hz / 200 ms | 0.001°C |
| 50 Hz / 20 ms | 0.01°C |
| 1000 Hz / 1 ms | 0.1°C |

9.32.3.9.5 Configuration

9.32.3.9.5.1 Input filter

Name:
ConfigOutput01

This register can be used to configure the filter time for all analog inputs.

| Data type | Value | Filter | Filter time |
|-----------|-------|--|-------------|
| USINT | 0 | 15 Hz | 66.7 ms |
| | 1 | 25 Hz | 40 ms |
| | 2 | 30 Hz | 33.3 ms |
| | 3 | 50 Hz | 20 ms |
| | 4 | 60 Hz | 16.7 ms |
| | 5 | 100 Hz | 10 ms |
| | 6 | 500 Hz | 2 ms |
| | 7 | 1000 Hz | 1 ms |
| | 8 | 10 Hz (bus controller default setting) | 100 ms |
| | 9 | 5 Hz | 200 ms |
| | 10 | 25 Hz | 400 ms |

9.32.3.9.5.2 Sensor type and channel disabling

Name:

ConfigOutput02

This register can be used to configure the sensor type for individual channels.

This module is designed for temperature and resistance measurement. The sensor type must be specified because of the different calibration values for temperature and resistance.

The default setting for all channels is ON.

| Data type | Value | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| USINT | See bit structure. | 17 |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------|--------------|---|
| 0 - 3 | Channel 1 | 0000 | Reserved |
| | | 0001 | Sensor type PT100 resolution 1mK (bus controller default setting) |
| | | 0010 | Resistance measurement 0.5 Ω to 390 Ω , resolution 1 m Ω |
| | | 0011 to 0110 | Reserved |
| | | 0111 | Channel disabled |
| | | 1xxx | Reserved |
| 4 - 7 | Channel 2 | 0000 | Reserved |
| | | 0001 | Sensor type PT100 resolution 1mK (bus controller default setting) |
| | | 0010 | Resistance measurement 0.5 Ω to 390 Ω , resolution 1 m Ω |
| | | 0011 to 0110 | Reserved |
| | | 0111 | Channel disabled |
| | | 1xxx | Reserved |

9.32.3.9.6 Communication

9.32.3.9.6.1 Analog measurement inputs

Name:

Temperatur01 to Temperatur02

Resistor01 to Resistor02

These registers are used to indicate the analog input values depending on the configured operating mode. Different resistance or temperature measurements will result in different value ranges and data types.

| Name | Data type | Input signal | Digital value |
|------------------------------|-----------|--|--|
| Temperatur01 to Temperatur02 | DINT | PT100 sensor type | -200000 to +850000 (for -200 to +850°C) |
| Resistor01 to Resistor02 | UDINT | Resistance measurement 0.5 to 390 Ω | 500 to 390000 (resolution 0.001 Ω) |

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x80000000 is output.
- After switching the sensor type, 0x80000000 is output until the first conversion.
- If the input is not switched on, 0x80000000 is output.

9.32.3.9.6.2 I/O cycle counter

Name:

IOCycleCounter

The cyclic counter increases after all input data has been updated.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Repeating counter |

9.32.3.9.6.3 Input status

Name:
StatusInput01

The module's inputs are monitored. A change in the monitoring status generates an error message.
After an error, it takes about 15 filter times until a valid value is available again.

| Data type | Value |
|-----------|--------------------|
| USINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------|-------|----------------------------|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Lower limit value exceeded |
| | | 10 | Upper limit value exceeded |
| | | 11 | Open line |
| 2 - 3 | Channel 2 | 00 | No error |
| | | 01 | Lower limit value exceeded |
| | | 10 | Upper limit value exceeded |
| | | 11 | Open line |
| 4 - 7 | Reserved | 0 | |

Analog value in the event of error

In addition to the status info, the error type also sets the analog value as follows:

| Error status | Temperature measurement - Digital value for error | Resistance measurement - Digital value for error |
|----------------------------|---|--|
| Open line | +2147483647 (0x7FFFFFFF) | +4294967295 (0xFFFFFFFF) |
| Upper limit value exceeded | +2147483647 (0x7FFFFFFF) | +4294967295 (0xFFFFFFFF) |
| Lower limit value exceeded | -2147483647 (0x80000001) | -2147483647 (0x80000001) |
| Invalid value | -2147483648 (0x80000000) | -2147483648 (0x80000000) |

9.32.3.9.7 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.32.3.9.8 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 1x filter time |

9.32.4 X20AT2402

Data sheet version: 3.09

9.32.4.1 General information

The module is equipped with 2 inputs for J, K, N, S, B and R thermocouple sensors. The module has an integrated terminal temperature compensation.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 inputs for thermocouples
- For sensor types J, K, N, S, B, R
- Additional direct raw value measurement
- Integrated terminal temperature compensation
- Configurable filter time

9.32.4.2 Order data

| Model number | Short description | Figure |
|--------------|--|--|
| | Temperature measurement |  |
| X20AT2402 | X20 temperature input module, 2 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB06 | X20 terminal block, 6-pin, 24 VDC keyed | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |
| | | |

- 1) Based on the current measured value.
2) Based on the entire measurement range.

9.32.4.4 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-----------------------------|------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Single flash | Warning/Error on an I/O channel. Overflow or underflow of the analog inputs. |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1 - 2 | Green | Off | The input is switched off |
| | | | Blinking | Overflow, underflow or open line |
| | | | On | Analog/digital converter running, value OK |

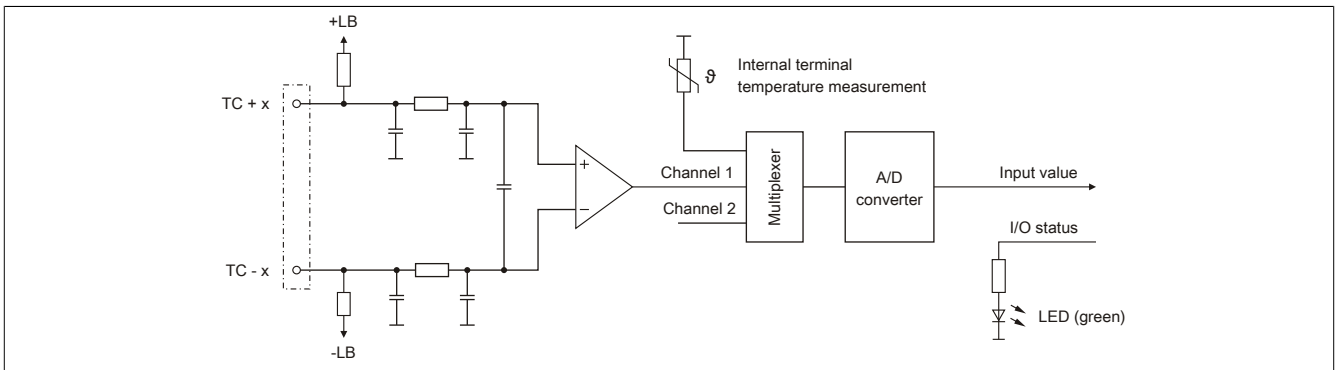

9.32.4.5 Pinout

9.32.4.6 Connection example

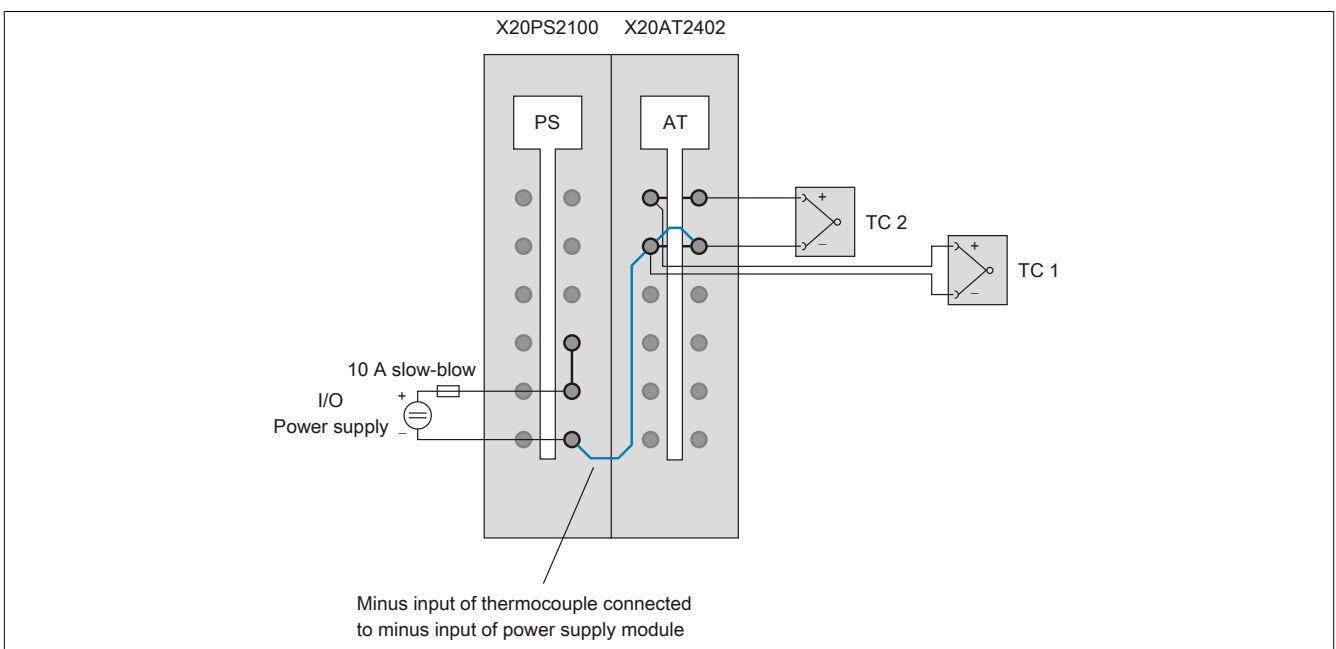

9.32.4.7 Input circuit diagram

9.32.4.8 Ceramic heating element with integrated thermo elements

We recommend connecting the minus input of the thermo element to the minus input of the supply feed module. This prevents potential measurement errors caused by ripple voltage effects in the measurement signal.

9.32.4.9 External cold junction

General information

An external cold junction temperature value can be predefined for the module for measurement value correction. This makes it possible to set up an external cold junction. The same external cold junction temperature is used for measurement value correction on all channels.

An external cold junction makes sense in the following applications and situations:

- Large distances between the controller and measurement point
- To increase precision

To bridge large distances

Setting up an external cold junction is recommended when there are large distances between the controller and the measurement point. The thermocouple voltage is routed from the external cold junction to the terminal on the X20AT2402 via copper wires. The temperature measured at the external cold junction (e.g. with PT100 - X20AT2222) is stored in the I/O area of the X20AT2402 module. The X20AT2402 uses the measured voltage and the cold junction temperature to internally calculate the needed thermocouple temperature.

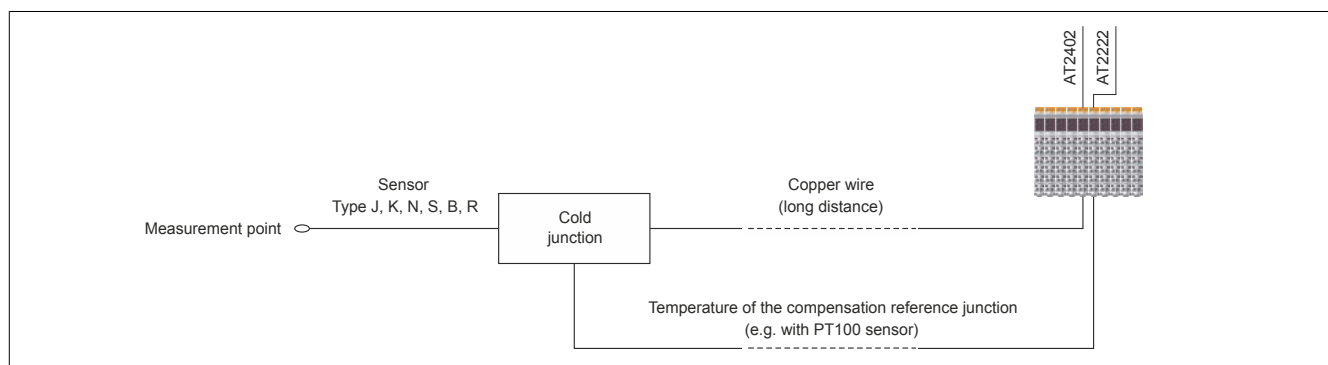

Figure 366: External cold junction for bridging large distances

Increased precision

Setting up an external cold junction is recommended to increase precision. The external cold junction is set up as described above. The installation of an external cold junction is especially helpful in the following cases:

- A module consuming more power than 1 W is connected in addition to the X20AT2402.
- No modules but the X20AT2402 are connected
- With strongly fluctuating ambient conditions (draft, temperature)

9.32.4.10 Register description

9.32.4.10.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.32.4.10.2 Function model 0 - default

| Register | Name | Data type | Read | | Write | |
|----------------------|--|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |
| 24 | ConfigOutput01 (Input filter / ambient conditions) | USINT | | | | • |
| 26 | ConfigOutput02 (Sensor type) | USINT | | | | • |
| 27 | ConfigOutput03 (Channel disabling) | USINT | | | | • |
| Communication | | | | | | |
| 0 | Temperature01 | INT | • | | | |
| 2 | Temperature02 | INT | • | | | |
| 28 | IOCycleCounter | USINT | • | | | |
| 30 | StatusInput01 | USINT | • | | | |
| 14 | CompensationTemperature | INT | | • | | |

9.32.4.10.3 Function model 1 - External cold junction temperature

| Register | Name | Data type | Read | | Write | |
|----------------------|--|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |
| 24 | ConfigOutput01 (Input filter / ambient conditions) | USINT | | | | • |
| 26 | ConfigOutput02 (Sensor type) | USINT | | | | • |
| 27 | ConfigOutput03 (Channel disabling) | USINT | | | | • |
| Communication | | | | | | |
| 12 | ExternalCompensationTemperature | INT | | | • | |
| 0 | Temperature01 | INT | • | | | |
| 2 | Temperature02 | INT | • | | | |
| 28 | IOCycleCounter | USINT | • | | | |
| 30 | StatusInput01 | USINT | • | | | |

9.32.4.10.4 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------------------|----------------------|--|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | | |
| 24 | - | ConfigOutput01 (Input filter / ambient conditions) | USINT | | | | • |
| 26 | - | ConfigOutput02 (Sensor type) | USINT | | | | • |
| 27 | - | ConfigOutput03 (Channel disabling) | USINT | | | | • |
| Communication | | | | | | | |
| 0 | 0 | Temperature01 | INT | • | | | |
| 2 | 2 | Temperature02 | INT | • | | | |
| 28 | - | IOCycleCounter | USINT | | • | | |
| 30 | - | StatusInput01 | USINT | | • | | |
| 14 | - | CompensationTemperature | INT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.32.4.10.4.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "[Using I/O modules on the bus controller](#)" on page 3789.

9.32.4.10.4.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.32.4.10.5 General information

9.32.4.10.5.1 Raw value measurement

If a sensor type other than J, K, N, S, B or R is used, the terminal temperature must be measured on at least one input. Based on this value, the user must then implement terminal temperature compensation.

9.32.4.10.5.2 Timing

The timing for acquiring measurement values is determined by the converter hardware. All enabled inputs are converted during each conversion cycle. In addition, the terminal temperature is measured (not in function model 1).

Any inputs that are not needed can be switched off, which reduces the I/O update time. Inputs can also be only switched off temporarily. Measuring the terminal temperature is switched off in function model 1.

9.32.4.10.5.3 Conversion time

The conversion time depends on the number of channels and the function model. For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

| Function model | Conversion time |
|----------------------|--|
| Model 0 - n channels | $(n + 1) \cdot (2 \cdot \text{Filter time} + 200 \mu\text{s})$ |
| Model 1 - n channels | $n \cdot (2 \cdot \text{Filter time} + 200 \mu\text{s})$ |
| Model 1 - 1 channel | Equal to the filter time |

Examples

Inputs are filtered using a 50 Hz filter.

| | Example 1 | | Example 2 | |
|--|------------------|------------------|------------------|------------------|
| | Function model 0 | Function model 1 | Function model 0 | Function model 1 |
| Switched on inputs | 1 | 1 | 1 - 2 | 1 - 2 |
| Input conversion times | 40.2 ms | 20 ms | 80.4 ms | 80.4 ms |
| Conversion time for the terminal temperature | 40.2 ms | - | 40.2 ms | - |
| Total conversion time | 80.4 ms | 20 ms | 120.6 ms | 80.4 ms |

9.32.4.10.6 Configuration

9.32.4.10.6.1 Input filter and ambient conditions

Name:

ConfigOutput01

This register configures input filters and ambient conditions.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| USINT | See bit structure. | 3 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------|--------------|---|
| 0 - 3 | Input filter | 0000 | 15 Hz |
| | | 0001 | 25 Hz |
| | | 0010 | 30 Hz |
| | | 0011 | 50 Hz (bus controller default setting) |
| | | 0100 | 60 Hz |
| | | 0101 | 100 Hz |
| | | 0110 | 500 Hz |
| | | 0111 | 1000 Hz |
| | | 1000 to 1111 | Not permitted |
| 4 - 7 | Environmental conditions | 0000 | Default, no calculation for adjustment (bus controller default setting) |
| | | 0001 | Power dissipation less than 0.2 W |
| | | 0010 | Power dissipation less than 1 W |
| | | 0011 | Power dissipation more than 1 W |
| | | 0100 to 1111 | Not permitted |

Input filter

The filter time for all analog inputs is defined using the input filter parameter.

| Value | Filter | Filter time | Digital converter resolution |
|-------|---------|-------------|------------------------------|
| 0 | 15 Hz | 66.7 ms | 16-bit |
| 1 | 25 Hz | 40 ms | 16-bit |
| 2 | 30 Hz | 33.3 ms | 16-bit |
| 3 | 50 Hz | 20 ms | 16-bit |
| 4 | 60 Hz | 16.7 ms | 16-bit |
| 5 | 100 Hz | 10 ms | 16-bit |
| 6 | 500 Hz | 2 ms | 16-bit |
| 7 | 1000 Hz | 1 ms | 16-bit |

Environmental conditions

Ambient conditions are set in order to adjust the internal terminal temperature characteristic curve to the type and amount of generated heat dissipated to the module.

This selection is based on the power consumption of the modules connected immediately to the left and right on the X2X Link. Power consumption values can also be found in the technical data for the corresponding module. The higher value is used for the configuration.

9.32.4.10.6.2 Sensor type

Name:

ConfigOutput02

This module is designed for a wide range of sensor types. The sensor type must be configured because of the different alignment values.

| Data type | Value | Information |
|-----------|----------|--|
| USINT | 0 | Conversion switched off |
| | 1 | Sensor type J (bus controller default setting) |
| | 2 | Sensor type K |
| | 3 | Sensor type S |
| | 4 | Sensor type N |
| | 5 | Conversion switched off |
| | 6 | Raw value without linearization and terminal temperature compensation: Resolution 1.0625 μ V for a measurement range of ± 35 mV |
| | 7 | Raw value without linearization and terminal temperature compensation: Resolution 2.125 μ V for a measurement range of ± 70 mV |
| | 8 - 63 | Conversion switched off |
| | 64 | Sensor type R |
| | 65 - 71 | Conversion switched off |
| | 72 | Sensor type B |
| | 73 - 255 | Conversion switched off |

9.32.4.10.6.3 Channel disabling

Name:

ConfigOutput03

By default, all channels are switched on. To save time, individual channels can be switched off (see "[Conversion time](#)" on page 3674).

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| USINT | See bit structure. | 3 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|--|
| 0 | Channel 1 | 0 | Off |
| | | 1 | Switched on (bus controller default setting) |
| 1 | Channel 2 | 0 | Off |
| | | 1 | Switched on (bus controller default setting) |
| 2 - 7 | Reserved | 0 | |

9.32.4.10.7 Communication

9.32.4.10.7.1 Analog inputs

Name:

Temperature01 to Temperature02

Analog input value depending on the configured sensor type:

| Data type | Values | Input signal |
|-----------|---|--|
| INT | -2100 to +12000 (for -210.0°C to +1200.0°C) | Type J (FeCuNi) |
| | -2700 to +13720 (for -270.0°C to +1372.0°C) | Type K (NiCrNi) |
| | -2700 to +13000 (for -270.0°C to +1300.0°C) | Type N (NiCrSi) |
| | -500 to +17680 (for -50.0°C to +1768.0°C) | Type S (PtRhPt) |
| | 0 to +18200 (for 0°C to +1820.0°C) | Type B (PtRhPt) |
| | -500 to +16640 (for -50.0°C to +1664.0°C) | Type R (PtRhPt) |
| | -32,768 to +32,767 | Raw value without linearization and terminal temperature compensation: Resolution 1.0625 µV for a measurement range of ±35 mV |
| | -32,768 to +32,767 | Raw value without linearization and terminal temperature compensation: Resolution 2.125 µV for a measurement range of ±70 mV |

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is not switched on, 0x8000 is output.

9.32.4.10.7.2 I/O cycle counter

Name:

IOCycleCounter

The cyclic counter increases after all input data has been updated.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Repeating counter |

9.32.4.10.7.3 Input status

Name:

StatusInput01

The module's inputs are monitored. A change in the monitoring status generates an error message.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Lower limit value undershot |
| | | 10 | Upper limit value overshoot |
| | | 11 | Open circuit |
| 2 - 3 | Channel 2 | 00 | No error |
| | | 01 | Lower limit value undershot |
| | | 10 | Upper limit value overshoot |
| | | 11 | Open circuit |
| 4 - 7 | Reserved | 0 | |

Analog value in the event of error

In addition to the status info, the error type also sets the analog value as follows:

| Error status | Digital value for error |
|----------------------------|-------------------------|
| Open line | +32767 (0x7FFF) |
| Upper limit value exceeded | +32767 (0x7FFF) |
| Lower limit value exceeded | -32767 (0x8001) |
| Invalid value | -32768 (0x8000) |

9.32.4.10.7.4 Reads the internal cold junction temperature

Name:

CompensationTemperature

The internal cold junction temperature is stored in this register.

| Data type | Value | Information |
|-----------|-------------|--|
| INT | -250 to 850 | Internal cold junction temperature (PT1000): -25.0 to 85.0°C |

9.32.4.10.7.5 Defines the external cold junction temperature

Name:

ExternalCompensationTemperature

The external cold junction temperature is defined in this register.

| Data type | Value | Information |
|-----------|-------------|---|
| INT | -250 to 850 | External cold junction temperature: -25.0 to 85.0°C |

9.32.4.10.8 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 150 µs |

9.32.4.10.9 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

For the formulas listed in the table, 'n' corresponds to the number of channels that are switched on.

| Function model 0 | |
|------------------|---|
| n inputs | $(n + 1) \cdot (2 \times \text{Filter time} + 200 \mu\text{s})$ |
| Function model 1 | |
| 1 input | Equal to the filter time |
| n inputs | $n \cdot (2 \times \text{Filter time} + 200 \mu\text{s})$ |

9.32.5 X20(c)AT4222

Data sheet version: 3.20

9.32.5.1 General information

The module is equipped with 4 inputs for PT100/PT1000 resistance temperature measurement.

- 4 inputs for resistance temperature measurement
- For PT100 and PT1000
- Configurable sensor type per channel
- Direct resistance measurement
- Configurable 2- or 3- wire connections per module
- Configurable filter time

9.32.5.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.32.5.2.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.32.5.5 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

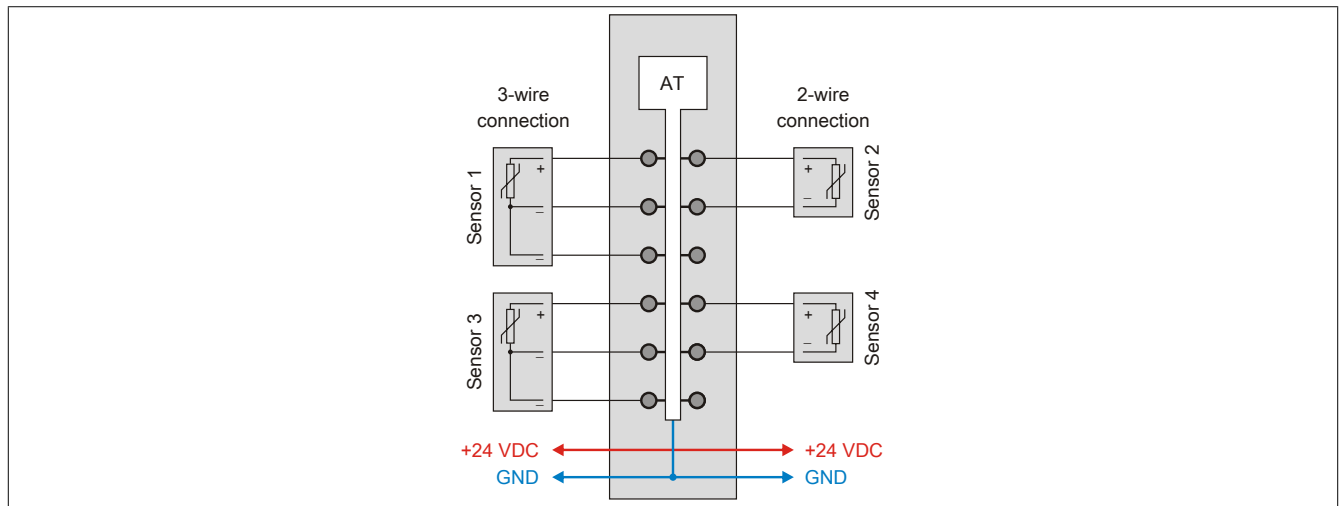

| Figure | LED | Color | Status | Description |
|---|-------|-----------------------------|------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Single flash | Warning/Error on an I/O channel. Overflow or underflow of the analog inputs. |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1 - 4 | Green | Off | The input is switched off |
| | | | Blinking | Overflow, underflow or open line |
| | | | On | Analog/digital converter running, value OK |

9.32.5.6 Pinout

Channels that are not being used should be disabled.

9.32.5.9 Register description

9.32.5.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.32.5.9.2 Function model 0 - "3-wire connections" and function model 1 - "2-wire connections"

With this module, the type of connection is selected using function models 0 and 1.

| Function model | Connection type |
|----------------|-------------------------------|
| 0 | 3-wire connections (standard) |
| 1 | 2-wire connections |

The registers applied are identical for both function models:

| Register | Name | Data type | Read | | Write | |
|----------------------|---|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |
| 16 | ConfigOutput01 (input filter) | USINT | | | | • |
| 18 | ConfigOutput02 (sensor configuration) | UINT | | | | • |
| Communication | | | | | | |
| 0 | Temperature01 | INT | • | | | |
| | Resistor01 | UINT | | | | |
| 2 | Temperature02 | INT | • | | | |
| | Resistor02 | UINT | | | | |
| 4 | Temperature03 | INT | • | | | |
| | Resistor03 | UINT | | | | |
| 6 | Temperature04 | INT | • | | | |
| | Resistor04 | UINT | | | | |
| 28 | IOCycleCounter | USINT | • | | | |
| 30 | StatusInput01 | USINT | • | | | |

9.32.5.9.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------------------|----------------------|---|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | | |
| 16 | - | ConfigOutput01 (input filter) | USINT | | | | • |
| 18 | - | ConfigOutput02 (sensor configuration) | UINT | | | | • |
| Communication | | | | | | | |
| 0 | 0 | Temperature01 | INT | • | | | |
| | 0 | Resistor01 | UINT | | | | |
| 2 | 2 | Temperature02 | INT | • | | | |
| | 2 | Resistor02 | UINT | | | | |
| 4 | 4 | Temperature03 | INT | • | | | |
| | 4 | Resistor03 | UINT | | | | |
| 6 | 6 | Temperature04 | INT | • | | | |
| | 6 | Resistor04 | UINT | | | | |
| 28 | - | IOCycleCounter | USINT | | • | | |
| 30 | - | StatusInput01 | USINT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.32.5.9.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.32.5.9.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.32.5.9.4 General information

9.32.5.9.4.1 Analog inputs

The module outputs the converted analog values to the registers. Other ranges of values or data types result depending on resistance or temperature measurement.

Information:

Operating channels outside specifications can affect neighboring channels.

9.32.5.9.4.2 Timing

The timing for acquiring measured values is controlled by the converter hardware. All switched-on inputs are converted during each conversion cycle and transferred halfway through the X2X Link cycle.

9.32.5.9.4.3 Conversion time

The conversion time for the channels depends on their use. For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

| Use of the channels | Conversion time |
|--|--|
| 1 channel | 1 · Filter time |
| n channels with the same sensor type | $n \cdot (20 \text{ ms} + \text{Filter time})$ |
| n channels with different sensor types | $n \cdot (20 \text{ ms} + 2 \cdot \text{Filter time})$ |

9.32.5.9.4.4 Reduced update time

Any inputs that are not needed can be switched off, which reduces the I/O update time. Inputs can also be only switched off temporarily.

Calculating the time saved

The amount of time saved can be calculated with the following formula. And "n" corresponds to the number of inputs that are switched off.

$$\text{Time saved} = n \cdot (20 \text{ ms} + \text{filter time})$$

Examples

Inputs are filtered using a 60 Hz filter.

| | Example 1 | Example 2 | Example 3 |
|--------------------|-----------|-----------|-----------|
| Switched on inputs | 1 | 1 and 3 | 1 to 4 |
| Conversion time | 16.7 ms | 73.4 ms | 146.8 ms |

9.32.5.9.5 Configuration

9.32.5.9.5.1 Input filter

Name:

ConfigOutput01

The filter time of all analog inputs is defined in this register.

| Data type | Value | Filter | Filter time |
|-----------|-------|--|-------------|
| USINT | 0 | 15 Hz | 66.7 ms |
| | 1 | 25 Hz | 40 ms |
| | 2 | 30 Hz | 33.3 ms |
| | 3 | 50 Hz (bus controller default setting) | 20 ms |
| | 4 | 60 Hz | 16.7 ms |
| | 5 | 100 Hz | 10 ms |
| | 6 | 500 Hz | 2 ms |
| | 7 | 1000 Hz | 1 ms |

9.32.5.9.5.2 Sensor configuration

Name:

ConfigOutput02

The sensor type of the individual channels is configured in this register.

This module is designed for temperature and resistance measurement. Due to different adjustment values for temperature and resistance, the sensor type must be selected.

By default, all channels are switched on. To save time, individual channels can be switched off (see "[Reduced update time](#)" on page 3685).

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 8738 |

Bit structure:

| Bit | Description | Value | Information |
|---------|-------------|-------------|--|
| 0 - 3 | Channel 1 | 0000 - 0001 | Reserved |
| | | 0010 | Sensor type PT100 (bus controller default setting) |
| | | 0011 | PT1000 sensor type |
| | | 0100 | Reserved (channel switched off) |
| | | 0101 | Resistance measurement 0.1 to 4500 Ω |
| | | 0110 | Resistance measurement 0.05 to 2250 Ω |
| | | 0111 | Channel switched off |
| | | 1000 - 1111 | Reserved |
| ... | ... | ... | ... |
| 12 - 15 | Channel 4 | 0000 - 0001 | Reserved |
| | | 0010 | Sensor type PT100 (bus controller default setting) |
| | | 0011 | PT1000 sensor type |
| | | 0100 | Reserved (channel switched off) |
| | | 0101 | Resistance measurement 0.1 to 4500 Ω |
| | | 0110 | Resistance measurement 0.05 to 2250 Ω |
| | | 0111 | Channel switched off |
| | | 1000 - 1111 | Reserved |

9.32.5.9.6 Communication

9.32.5.9.6.1 Input values of analog inputs

Name:

Temperature01 to Temperature04

Resistor01 to Resistor04

This register contains the analog input values depending on the configured operating mode.

| Data type | Digital value | Input signal |
|-----------|---------------------------------------|---------------------------------------|
| INT | -2000 to 8500 (for -200.0 to 850.0°C) | PT100 sensor type |
| | -2000 to 8500 (for -200.0 to 850.0°C) | PT1000 sensor type |
| UINT | 1 to 45000 (resolution 0.1 Ω) | Resistance measurement 0.1 to 4500 Ω |
| | 1 to 45000 (resolution 0.05 Ω) | Resistance measurement 0.05 to 2250 Ω |

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the operating mode until the first conversion:
 - From "Resistance measurement" to "Sensor type PTxx": 0x8000
 - From "Sensor type PTxx" to "Resistance measurement": 0xFFFF
- If the input is not switched on, 0x8000 is output.

9.32.5.9.6.2 I/O cycle counter

Name:

IOCycleCounter

The cyclic counter increases after all input data has been updated.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Repeating counter |

9.32.5.9.6.3 Status of the inputs

Name:

StatusInput01

The module's inputs are monitored. A change in the monitoring status is actively transmitted as an error message.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Lower limit value undershot |
| | | 10 | Upper limit value overshoot |
| | | 11 | Open circuit |
| ... | ... | ... | ... |
| 6 - 7 | Channel 4 | 00 | No error |
| | | 01 | Lower limit value undershot |
| | | 10 | Upper limit value overshoot |
| | | 11 | Open circuit |

Limiting the analog value

In addition to the status information, the analog value is fixed to the values listed below by default in an error state.

| Error state | Temperature measurement Digital value on error | Resistance measurement Digital value on error |
|------------------------------|---|--|
| Open circuit | 32767 (0x7FFF) | 65535 (0xFFFF) |
| Upper limit value overshoot | 32767 (0x7FFF) | 65535 (0xFFFF) |
| Lower limit value undershoot | -32767 (0x8001) | 0 (0x0000) |
| Invalid value | -32768 (0x8000) ¹⁾ | 65535 (0xFFFF) |
| | 32767 (0x7FFF) ²⁾ | |
| | 65535 (0xFFFF) ³⁾ | |

1) Default value or channel was disabled in the I/O configuration.

2) After switching off the channel during operation.

3) Value in function model 254 - Bus controller.

9.32.5.9.7 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|--------------------|--|
| 100 μ s | |

9.32.5.9.8 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|-------------------------|--|
| 1 input | Equal to the filter time |
| n inputs | $n \cdot (20 \text{ ms} + \text{filter time})$ |

9.32.6 X20AT4232

Data sheet version: 1.11

9.32.6.1 General information

This module is equipped with 4 inputs for NTC resistance temperature measurement (10 k Ω at 25°C). In addition, this module can measure resistance from 0 to 200 k Ω .

- 4 inputs for resistance temperature measurement
- For NTC resistance type 10 k Ω
- Resistance measurement 0 to 200 k Ω
- Configurable measurement type per channel
- 2-wire measurement
- Configurable filter time

Table 644: X20AT4232 - Technical data

- 1) Depends on the temperature sensor. This value applies when using Vishay sensor NTCLE100E3103GB0 $B_{25/85} = 3977$ and Vishay sensor NTCLE413E2103F400L $B_{25/85} = 3435$.
- 2) Based on the current resistance value.
- 3) Based on the entire resistance measurement range.

9.32.6.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

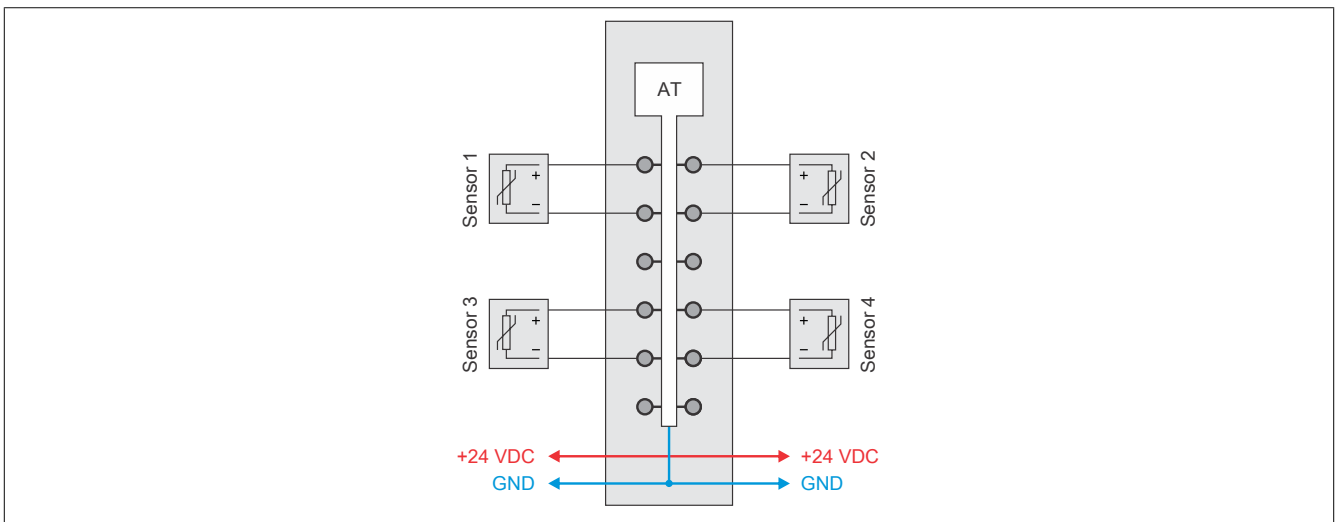

| Figure | LED | Color | Status | Description |
|---|-------|--------------------------------|------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Single flash | Warning/Error on an I/O channel. Overflow or underflow of the analog inputs. |
| | e + r | Solid red / Single green flash | Invalid firmware | |
| | 1 - 4 | Green | Off | The input is switched off |
| | | | Blinking | Overflow, underflow or open circuit |
| | | | On | Analog/digital converter running, value OK |

9.32.6.5 Pinout

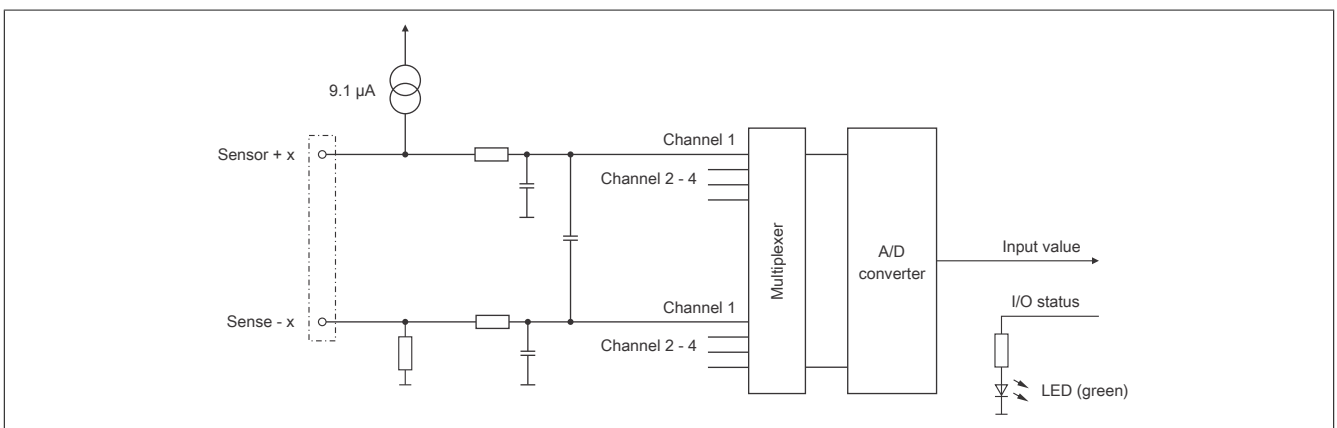

Channels that are not being used should be disabled.

9.32.6.6 Connection example

9.32.6.7 Input circuit diagram

9.32.6.8 Register description

9.32.6.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.32.6.8.2 Function model 0 - Standard

| Register | Name | Data type | Read | | Write | |
|----------------------|---------------------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |
| 16 | ConfigOutput01 (Input filter) | USINT | | | | • |
| 18 | ConfigOutput02 (Sensor configuration) | UINT | | | | • |
| Communication | | | | | | |
| 0 | Temperature01 | INT | • | | | |
| | Resistor01 | UINT | | | | |
| 2 | Temperature02 | INT | • | | | |
| | Resistor02 | UINT | | | | |
| 4 | Temperature03 | INT | • | | | |
| | Resistor03 | UINT | | | | |
| 6 | Temperature04 | INT | • | | | |
| | Resistor04 | UINT | | | | |
| 28 | IOCycleCounter | USINT | • | | | |
| 30 | StatusInput01 | USINT | • | | | |

9.32.6.8.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------------------|----------------------|---------------------------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | | |
| 16 | - | ConfigOutput01 (Input filter) | USINT | | | | • |
| 18 | - | ConfigOutput02 (Sensor configuration) | UINT | | | | • |
| Communication | | | | | | | |
| 0 | 0 | Temperature01 | INT | • | | | |
| | | Resistor01 | UINT | | | | |
| 2 | 2 | Temperature02 | INT | • | | | |
| | | Resistor02 | UINT | | | | |
| 4 | 4 | Temperature03 | INT | • | | | |
| | | Resistor03 | UINT | | | | |
| 6 | 6 | Temperature04 | INT | • | | | |
| | | Resistor04 | UINT | | | | |
| 28 | - | IOCycleCounter | USINT | | • | | |
| 30 | - | StatusInput01 | USINT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.32.6.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "[Using I/O modules on the bus controller](#)" on page 3789.

9.32.6.8.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.32.6.8.4 General information

9.32.6.8.4.1 Analog inputs

The module outputs the converted analog values to the registers. Other ranges of values or data types result depending on resistance or temperature measurement.

Information:

Operating channels outside specifications can affect neighboring channels.

9.32.6.8.4.2 Timing

The timing for acquiring measured values is controlled by the converter hardware. All switched-on inputs are converted during each conversion cycle and transferred halfway through the X2X Link cycle.

9.32.6.8.4.3 Conversion time

The conversion time for the channels depends on their use. For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

| Use of the channels | Conversion time |
|--|--|
| 1 channel | 1 · Filter time |
| n channels with the same sensor type | $n \cdot (20 \text{ ms} + \text{Filter time})$ |
| n channels with different sensor types | $n \cdot (20 \text{ ms} + 2 \cdot \text{Filter time})$ |

9.32.6.8.4.4 Reduced update time

Any inputs that are not needed can be switched off, which reduces the I/O update time. Inputs can also be only switched off temporarily.

Calculating the time saved

The amount of time saved can be calculated with the following formula. And "n" corresponds to the number of inputs that are switched off.

$$\text{Time saved} = n \cdot (20 \text{ ms} + \text{filter time})$$

Examples

Inputs are filtered using a 60 Hz filter.

| | Example 1 | Example 2 | Example 3 |
|--------------------|-----------|-----------|-----------|
| Switched on inputs | 1 | 1 and 3 | 1 to 4 |
| Conversion time | 16.7 ms | 73.4 ms | 146.8 ms |

9.32.6.8.5 Configuration

9.32.6.8.5.1 Input filter

Name:

ConfigOutput01

The filter time of all analog inputs is defined in this register.

| Data type | Value | Filter | Filter time |
|-----------|-------|--|-------------|
| USINT | 0 | 15 Hz | 66.7 ms |
| | 1 | 25 Hz | 40 ms |
| | 2 | 30 Hz | 33.3 ms |
| | 3 | 50 Hz (bus controller default setting) | 20 ms |
| | 4 | 60 Hz | 16.7 ms |

9.32.6.8.5.2 Sensor configuration

Name:

ConfigOutput02

This register can be used to configure the sensor type for individual channels.

This module is designed for temperature and resistance measurement. The sensor type must be specified because of the different calibration values for temperature and resistance.

The default setting for all channels is ON. To save time, individual channels can be switched off (see "[Reduced update time](#)" on page 3694).

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Name | Value | Information |
|---------|-----------|-------------|--|
| 0 - 3 | Channel 1 | 0000 | Sensor: NTC10K type 1 (bus controller default setting) ¹⁾ |
| | | 0001 | Sensor: NTC10K type 2 ²⁾ |
| | | 0010 | Reserved |
| | | 0011 | Reserved |
| | | 0100 | Channel switched off |
| | | 0101 | Resistance measurement 0 to 200 kΩ |
| | | 0110 | Reserved |
| | | 0111 | Channel switched off |
| | | 1000 - 1111 | Reserved |
| ... | ... | ... | ... |
| 12 - 15 | Channel 4 | 0000 | Sensor: NTC10K type 1 (bus controller default setting) ¹⁾ |
| | | 0001 | Sensor: NTC10K type 2 ²⁾ |
| | | 0010 | Reserved |
| | | 0011 | Reserved |
| | | 0100 | Channel switched off |
| | | 0101 | Resistance measurement 0 to 200 kΩ |
| | | 0110 | Reserved |
| | | 0111 | Channel switched off |
| | | 1000 - 1111 | Reserved |

1) Sensor NTC10K type 1: Vishay NTCLE100E3103GB0, $B_{25/85} = 3977$

2) Sensor NTC10K type 2: Vishay NTCLE413E2103F400L, $B_{25/85} = 3435$

9.32.6.8.6 Communication

9.32.6.8.6.1 Input values of analog inputs

Name:

Temperature01 to Temperature04

Resistor01 to Resistor04

This register is used to indicate the analog input values depending on the configured operating mode.

| Data type | Digital value | Input signal |
|-----------|-------------------------------------|------------------------------------|
| INT | -300 to 1000 (for -30.0 to 100.0°C) | Sensor NTC10K type 1 |
| | -300 to 1000 (for -30.0 to 100.0°C) | Sensor NTC10K type 2 |
| UINT | 0 to 40000 (resolution 5 Ω) | Resistance measurement 0 to 200 kΩ |

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is not switched on, 0xFFFF is output.

9.32.6.8.6.2 I/O cycle counter

Name:

IOCycleCounter

The cyclic counter increases after all input data has been updated.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Repeating counter |

9.32.6.8.6.3 Status of the inputs

Name:

StatusInput01

The module's inputs are monitored. A change in the monitoring status is actively transmitted as an error message.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Lower limit value undershot |
| | | 10 | Upper limit value overshoot |
| | | 11 | Open circuit |
| ... | | ... | |
| 6 - 7 | Channel 4 | 00 | No error |
| | | 01 | Lower limit value undershot |
| | | 10 | Upper limit value overshoot |
| | | 11 | Open circuit |

Limiting the analog value

In addition to the status information, the analog value is fixed to the values listed below by default in an error state.

| Error state | Temperature measurement Digital value on error | Resistance measurement Digital value on error |
|-----------------------------|---|--|
| Open circuit | 32767 (0x7FFF) | 65535 (0xFFFF) |
| Upper limit value overshoot | 32767 (0x7FFF) | 65535 (0xFFFF) |
| Lower limit value undershot | -32767 (0x8001) | 0 (0x0000) |
| Invalid value | -32768 (0x8000) ¹⁾ 32767 (0x7FFF) ²⁾ 65535 (0xFFFF) ³⁾ | 65535 (0xFFFF) |

- 1) Default value or channel was disabled in the I/O configuration.
- 2) After switching off the channel during operation.
- 3) Value in function model 254 - Bus controller.

9.32.6.8.7 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|--------------------|--|
| 100 μ s | |

9.32.6.8.8 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|-------------------------|--|
| 1 input | Equal to the filter time |
| n inputs | $n \cdot (20 \text{ ms} + \text{filter time})$ |

9.32.7 X20(c)AT6402

Data sheet version: 3.10

9.32.7.1 General information

The module is equipped with 6 inputs for J, K, N, S, B and R thermocouple sensors. The module has an integrated terminal temperature compensation.

- 6 inputs for thermocouples
- For sensor types J, K, N, S, B, R
- Additional direct raw value measurement
- Integrated terminal temperature compensation
- Configurable filter time

9.32.7.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.32.7.2.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.32.7.3 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | Temperature measurement |  |

9.32.7.5 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-----------------------------|------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Single flash | Warning/Error on an I/O channel. Overflow or underflow of the analog inputs. |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1 - 6 | Green | Off | The input is switched off |
| | | | Blinking | Overflow, underflow or open line |
| | | | On | Analog/digital converter running, value OK |

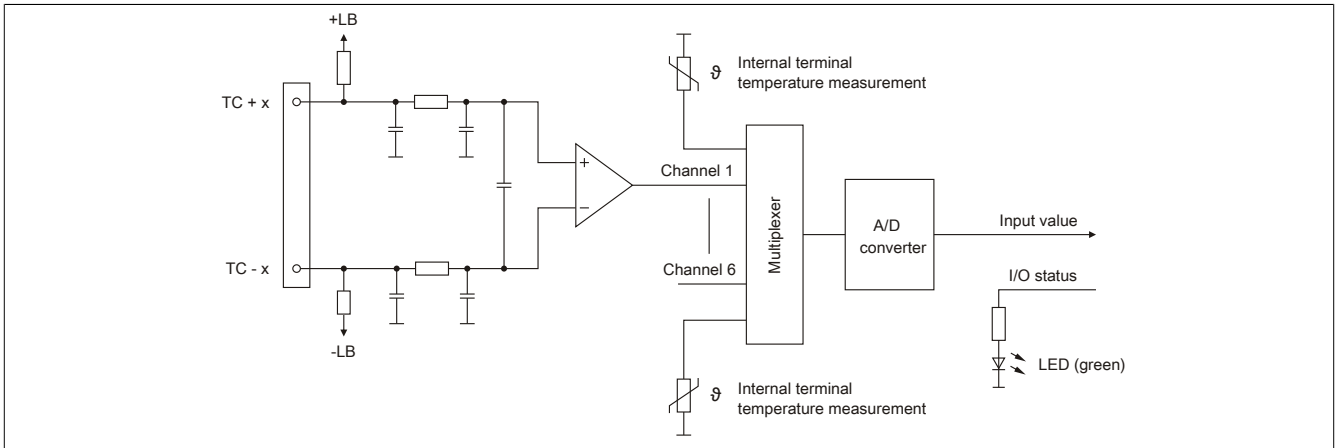

9.32.7.6 Pinout

9.32.7.7 Connection example

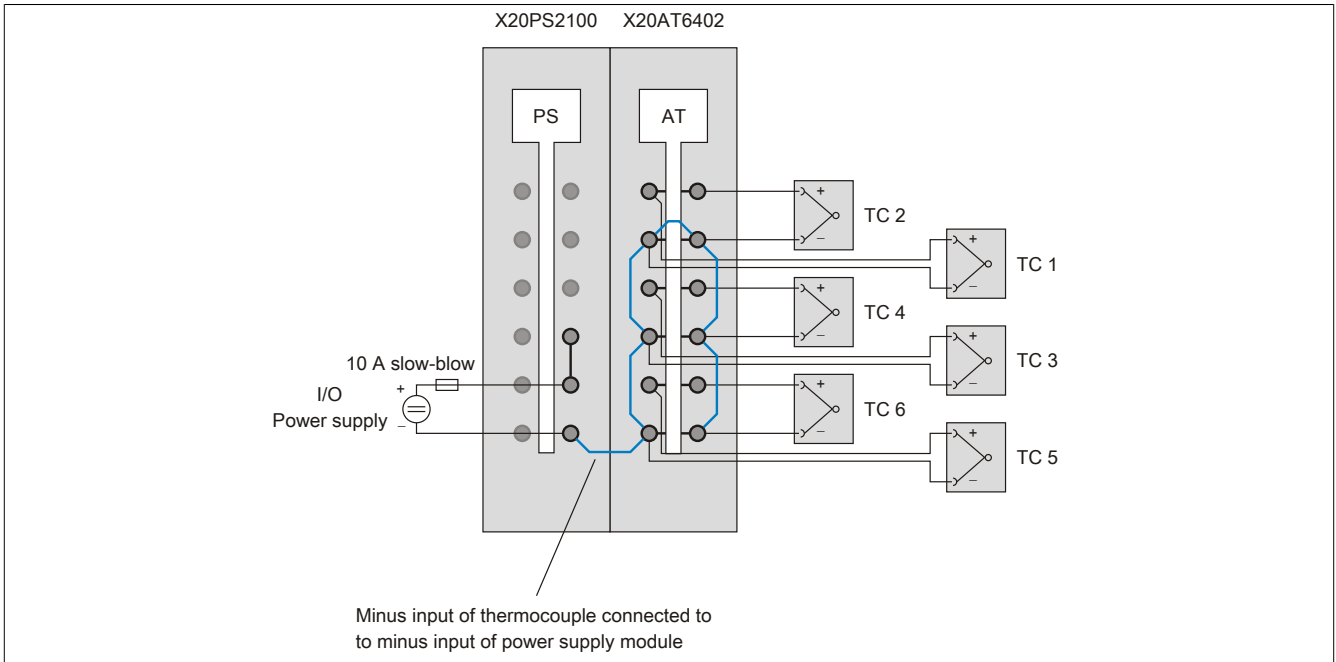

9.32.7.8 Input circuit diagram

9.32.7.9 Ceramic heating element with integrated thermo elements

We recommend connecting the minus input of the thermo element to the minus input of the supply feed module. This prevents potential measurement errors caused by ripple voltage effects in the measurement signal.

9.32.7.10 External cold junction

General information

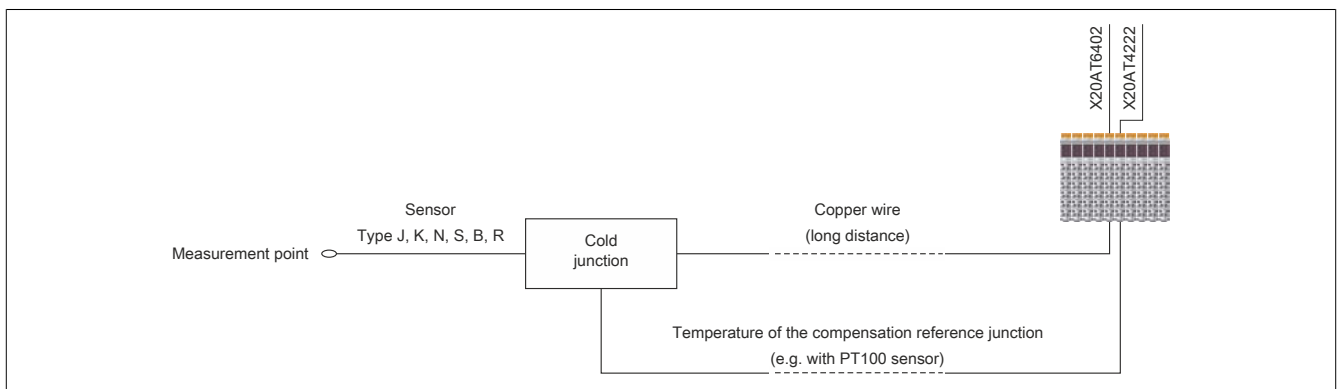

An external cold junction temperature value can be predefined for the module for measurement value correction. This makes it possible to set up an external cold junction. The same external cold junction temperature is used for measurement value correction on all channels.

An external cold junction makes sense in the following applications and situations:

- Large distances between the controller and measurement point
- To increase precision

To bridge large distances

Setting up an external cold junction is recommended when there are large distances between the controller and the measurement point. The thermocouple voltage is routed from the external cold junction to the terminal on the X20AT6402 via copper wires. The temperature measured at the external cold junction (e.g. with PT100 - X20AT4222) is stored in the I/O area of the X20AT6402 module. The X20AT6402 uses the measured voltage and the cold junction temperature to internally calculate the needed thermocouple temperature.

Increased precision

Setting up an external cold junction is recommended to increase precision. The external cold junction is set up as described above. The installation of an external cold junction is especially helpful in the following cases:

- A module consuming more power than 1 W is connected in addition to the X20AT6402.
- No modules but the X20AT6402 are connected
- With strongly fluctuating ambient conditions (draft, temperature)

9.32.7.11 Register description

9.32.7.11.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.32.7.11.2 Function model 0 - Standard

| 30 | - | StatusInput01 | USINT | | • | | |
| 31 | - | StatusInput02 | USINT | | • | | |
| 22 | - | CompensationTemperature | INT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.32.7.11.4.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.32.7.11.4.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.32.7.11.5 General information

9.32.7.11.5.1 Raw value measurement

If a sensor type other than J, K, N, S, B or R is used, the terminal temperature must be measured on at least one input. Based on this value, the user must then implement terminal temperature compensation.

9.32.7.11.5.2 Timing

The timing for acquiring measurement values is determined by the converter hardware. All enabled inputs are converted during each conversion cycle. In addition, the terminal temperature is measured (not in function model 1).

Any inputs that are not needed can be switched off, which reduces the I/O update time. Inputs can also be only switched off temporarily. Measuring the terminal temperature is switched off in function model 1.

9.32.7.11.5.3 Conversion time

The conversion time depends on the number of channels and the function model. For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

| Function model | Conversion time |
|----------------------|--|
| Model 0 - n channels | $(n + 1) \cdot (2 \cdot \text{Filter time} + 200 \mu\text{s})$ |
| Model 1 - n channels | $n \cdot (2 \cdot \text{Filter time} + 200 \mu\text{s})$ |
| Model 1 - 1 channel | Equal to the filter time |

Examples

Inputs are filtered using a 50 Hz filter.

| | Example 1 | | Example 2 | |
|--|------------------|------------------|------------------|------------------|
| | Function model 0 | Function model 1 | Function model 0 | Function model 1 |
| Switched on inputs | 1 | 1 | 1 - 6 | 1 - 6 |
| Input conversion times | 40.2 ms | 20 ms | 241.2 ms | 241.2 ms |
| Conversion time for the terminal temperature | 40.2 ms | - | 40.2 ms | - |
| Total conversion time | 80.4 ms | 20 ms | 281.4 ms | 241.2 ms |

9.32.7.11.6 Configuration

9.32.7.11.6.1 Input filter and ambient conditions

Name:

ConfigOutput01

This register configures input filters and ambient conditions.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| USINT | See bit structure. | 3 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------|--------------|---|
| 0 - 3 | Input filter | 0000 | 15 Hz |
| | | 0001 | 25 Hz |
| | | 0010 | 30 Hz |
| | | 0011 | 50 Hz (bus controller default setting) |
| | | 0100 | 60 Hz |
| | | 0101 | 100 Hz |
| | | 0110 | 500 Hz |
| | | 0111 | 1000 Hz |
| | | 1000 to 1111 | Not permitted |
| 4 - 7 | Environmental conditions | 0000 | Default, no calculation for adjustment (bus controller default setting) |
| | | 0001 | Power dissipation less than 0.2 W |
| | | 0010 | Power dissipation less than 1 W |
| | | 0011 | Power dissipation more than 1 W |
| | | 0100 to 1111 | Not permitted |

Input filter

The filter time for all analog inputs is defined using the input filter parameter.

| Value | Filter | Filter time | Digital converter resolution |
|-------|---------|-------------|------------------------------|
| 0 | 15 Hz | 66.7 ms | 16-bit |
| 1 | 25 Hz | 40 ms | 16-bit |
| 2 | 30 Hz | 33.3 ms | 16-bit |
| 3 | 50 Hz | 20 ms | 16-bit |
| 4 | 60 Hz | 16.7 ms | 16-bit |
| 5 | 100 Hz | 10 ms | 16-bit |
| 6 | 500 Hz | 2 ms | 16-bit |
| 7 | 1000 Hz | 1 ms | 16-bit |

Environmental conditions

Ambient conditions are set in order to adjust the internal terminal temperature characteristic curve to the type and amount of generated heat dissipated to the module.

This selection is based on the power consumption of the modules connected immediately to the left and right on the X2X Link. Power consumption values can also be found in the technical data for the corresponding module. The higher value is used for the configuration.

9.32.7.11.6.2 Sensor type

Name:

ConfigOutput02

This module is designed for a wide range of sensor types. The sensor type must be configured because of the different alignment values.

| Data type | Value | Information |
|-----------|----------|--|
| USINT | 0 | Conversion switched off |
| | 1 | Sensor type J (bus controller default setting) |
| | 2 | Sensor type K |
| | 3 | Sensor type S |
| | 4 | Sensor type N |
| | 5 | Conversion switched off |
| | 6 | Raw value without linearization and terminal temperature compensation: Resolution 1.0625 μ V for a measurement range of ± 35 mV |
| | 7 | Raw value without linearization and terminal temperature compensation: Resolution 2.125 μ V for a measurement range of ± 70 mV |
| | 8 - 63 | Conversion switched off |
| | 64 | Sensor type R |
| | 65 - 71 | Conversion switched off |
| | 72 | Sensor type B |
| | 73 - 255 | Conversion switched off |

9.32.7.11.6.3 Channel disabling

Name:

ConfigOutput03

By default, all channels are switched on. To save time, individual channels can be switched off (see "[Conversion time](#)" on page 3705).

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| USINT | See bit structure. | 63 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|--|
| 0 | Channel 1 | 0 | Off |
| | | 1 | Switched on (bus controller default setting) |
| | ... | ... | |
| 5 | Channel 6 | 0 | Off |
| | | 1 | Switched on (bus controller default setting) |
| 6 - 7 | Reserved | 0 | |

9.32.7.11.7 Communication

9.32.7.11.7.1 Analog inputs

Name:

Temperature01 to Temperature06

Analog input value depending on the configured sensor type:

| Data type | Values | Input signal |
|-----------|---|--|
| INT | -2100 to +12000 (for -210.0°C to +1200.0°C) | Type J (FeCuNi) |
| | -2700 to +13720 (for -270.0°C to +1372.0°C) | Type K (NiCrNi) |
| | -2700 to +13000 (for -270.0°C to +1300.0°C) | Type N (NiCrSi) |
| | -500 to +17680 (for -50.0°C to +1768.0°C) | Type S (PtRhPt) |
| | 0 to +18200 (for 0°C to +1820.0°C) | Type B (PtRhPt) |
| | -500 to +16640 (for -50.0°C to +1664.0°C) | Type R (PtRhPt) |
| | -32768 to +32767 | Raw value without linearization and terminal temperature compensation: Resolution 1.0625 μ V for a measurement range of ± 35 mV |
| | -32768 to +32767 | Raw value without linearization and terminal temperature compensation: Resolution 2.125 μ V for a measurement range of ± 70 mV |

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- After switching the sensor type from raw value measurement to "type x" measurement, 0x7FFF is output until the internal terminal temperature measurements have been performed (see "Input circuit diagram" on page 3702). In addition, the [StatusInput](#) bit "Upper limit value exceeded" associated with the channel is set.
- If the input is not switched on, 0x8000 is output.

9.32.7.11.7.2 I/O cycle counter

Name:

IOCycleCounter

The cyclic counter increases after all input data has been updated.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Repeating counter |

9.32.7.11.7.3 Input status

The module's inputs are monitored. A change in the monitoring status generates an error message.

In addition to the status info, the error type also sets the analog value as follows:

| Error status | Digital value for error |
|----------------------------|-------------------------|
| Open line | +32767 (0x7FFF) |
| Upper limit value exceeded | +32767 (0x7FFF) |
| Lower limit value exceeded | -32767 (0x8001) |
| Invalid value | -32768 (0x8000) |

Status of inputs 1 to 4

Name:

StatusInput01

The state of analog inputs 1 to 4 is represented in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Lower limit value undershot |
| | | 10 | Upper limit value overshoot |
| | | 11 | Open circuit |
| 2 - 3 | Channel 2 | x | Values, see channel 1 |
| 4 - 5 | Channel 3 | x | Values, see channel 1 |
| 6 - 7 | Channel 4 | x | Values, see channel 1 |

Status of inputs 5 to 6

Name:
StatusInput02

The state of analog inputs 5 to 6 is represented in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------|
| 0 - 1 | Channel 5 | 00 | No error |
| | | 01 | Lower limit value undershot |
| | | 10 | Upper limit value overshoot |
| | | 11 | Open circuit |
| 2 - 3 | Channel 6 | x | Values, see channel 5 |
| 4 - 7 | Reserved | 0 | |

9.32.7.11.7.4 Reads the internal cold junction temperature

Name:
CompensationTemperature

The internal cold junction temperature is stored in this register.

| Data type | Value | Information |
|-----------|-------------|--|
| INT | -250 to 850 | Internal cold junction temperature (PT1000): -25.0 to 85.0°C |

9.32.7.11.7.5 Defines the external cold junction temperature

Name:
ExternalCompensationTemperature

The external cold junction temperature is defined in this register.

| Data type | Value | Information |
|-----------|-------------|---|
| INT | -250 to 850 | External cold junction temperature: -25.0 to 85.0°C |

9.32.7.11.8 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 150 µs |

9.32.7.11.9 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

For the formulas listed in the table, 'n' corresponds to the number of channels that are switched on.

| Function model 0 | |
|------------------|---|
| n inputs | $(n + 1) \cdot (2 \times \text{Filter time} + 200 \mu\text{s})$ |
| Function model 1 | |
| 1 input | Equal to the filter time |
| n inputs | $n \cdot (2 \times \text{Filter time} + 200 \mu\text{s})$ |

9.32.8 X20ATA312

Data sheet version: 1.42

9.32.8.1 General information

The module is equipped with 2 inputs for PT100 4-line resistance temperature measurement.

- 2 inputs for resistance temperature measurement
- PT100 sensor
- Direct resistance measurement as well
- 4-wire measurement
- Filter time can be configured
- NetTime timestamp: Moment of measurement

NetTime timestamp of the measurement

For many applications, not only the measured value is important, but also the exact time of the measurement. The module is equipped with a NetTime timestamp function for this that supplies a timestamp for the recorded position and trigger time with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.32.8.2 Order data

| Model number | Short description | Figure |
|--------------|---|--|
| X20ATA312 | X20 temperature input module, 2 inputs for resistance measurement, PT100, resolution 0.01°C, 4-wire connections, NetTime function |  |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB1F | X20 terminal block, 16-pin, 24 VDC keyed | |

| Pitch | 12.5 ^{+0.2} mm |

Table 648: X20ATA312 - Technical data

- 1) To guarantee accuracy, modules with a power dissipation < 1.2 W must be connected to the left and right of this module.
- 2) Based on the current resistance value.
- 3) Based on the entire resistance measurement range.

9.32.8.4 Status LEDs

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

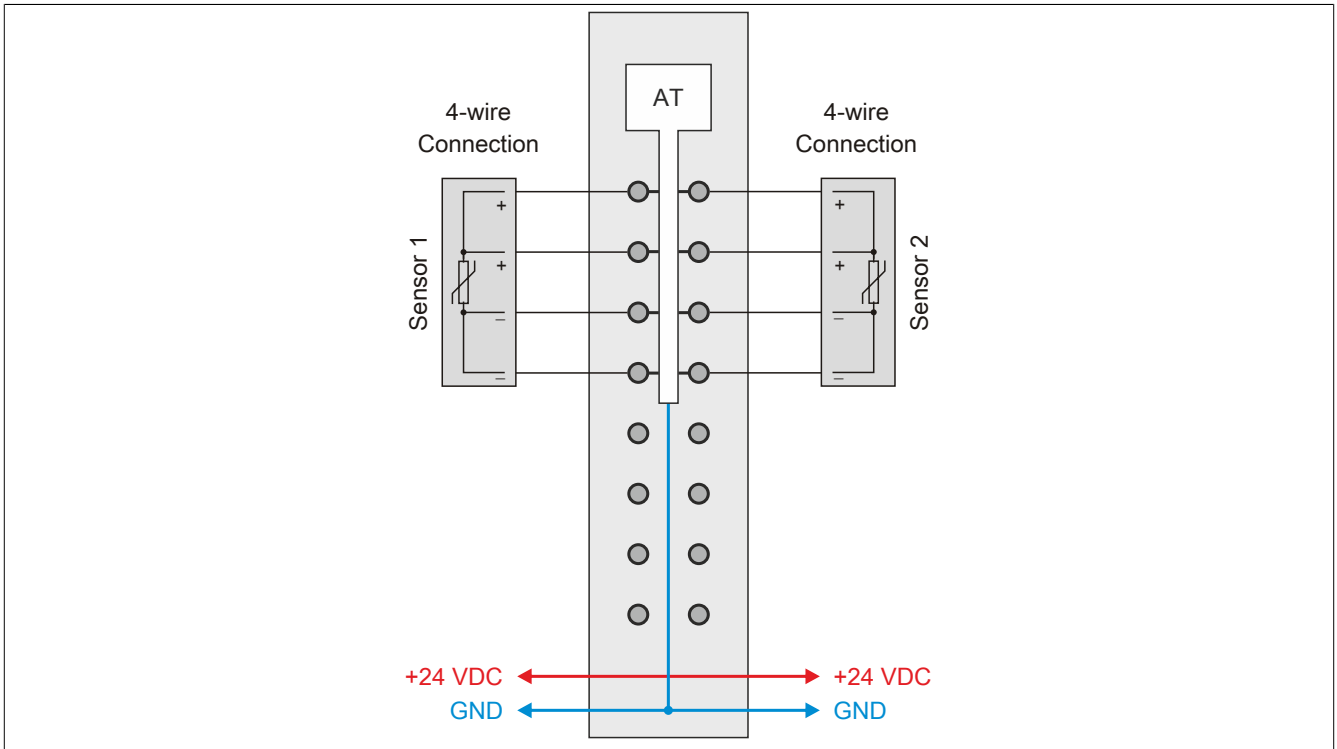

| Image | LED | Color | Status | Description |
|---|-----------------------------|------------------|----------------------------------|--|
|  | s | Green | Off | Module supply not connected |
| | | | Single flash | Reset mode |
| | | | Double flash | Mode BOOT (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | On | RUN mode | |
| | | Red | Off | Module supply not connected or everything OK |
| | | | On | Error or reset status |
| | | | Single flash | Parameter or conversion error ²⁾ |
| | Red on / Green single flash | Invalid firmware | | |
| | 1 - 2 | Green | Off | Input turned off or not supplied |
| | | | Single flash | Parameter error ²⁾ |
| | | | Double flash | Conversion error ²⁾ |
| Blinking | | | Overflow, underflow or open line | |
| On | | | A/D converter running, value OK | |

- 1) Depending on the configuration, a firmware update can take up to several minutes.
- 2) Parameter or converter errors are indicated simultaneously on the red "s" LED and the channel LED of the respective output.

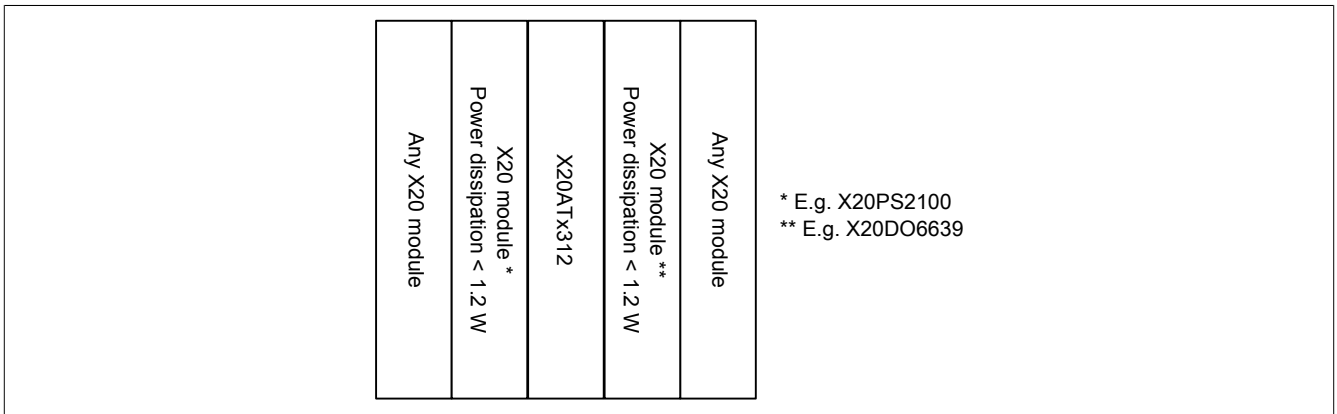

9.32.8.5 Pinout

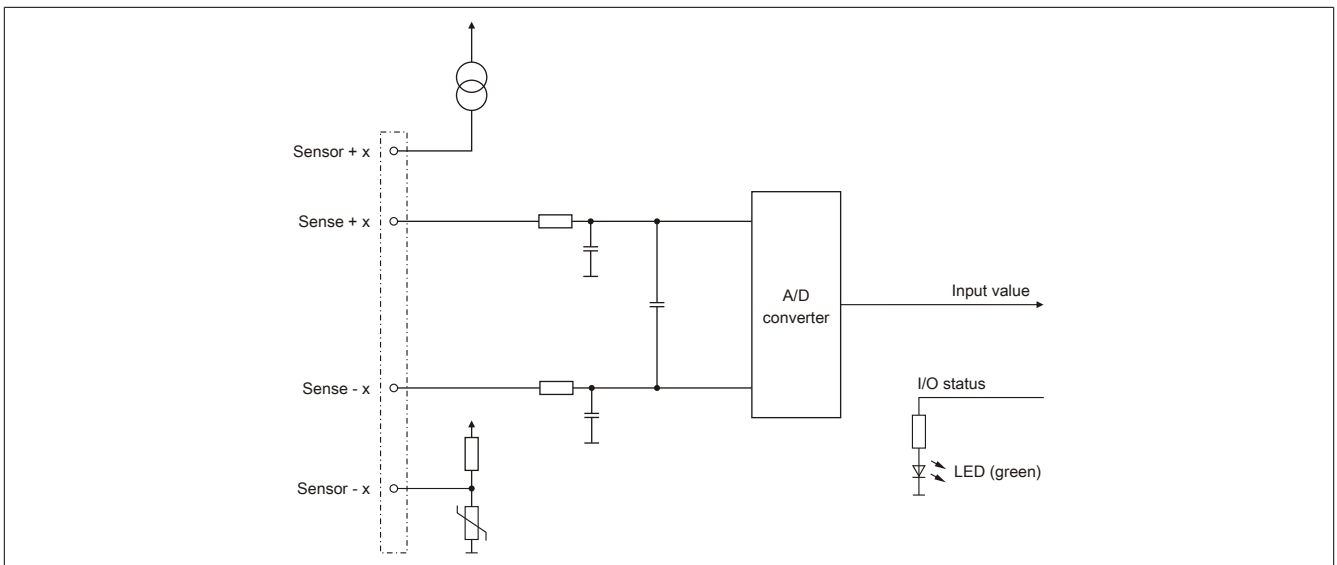

9.32.8.6 Connection example

To ensure accuracy, modules with a power consumption <math>< 1.2\text{ W}</math> must be inserted to the left and right of this modules.

9.32.8.7 Input circuit diagram

9.32.8.8 Register description

9.32.8.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.32.8.8.2 Function model 0 - Standard

| Register | Name | Data type | Read | | Write | |

1) The offset specifies where the register is within the CAN object.

9.32.8.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.32.8.8.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.32.8.8.4 Configuration of the A/D converter

9.32.8.8.4.1 Setting the conversion rate

Name:

InputFilter

Mit Hilfe dieses Registers wird die Abtastzeit des A/D-Wandlers konfiguriert.

| Datentyp | Werte | Filterzeit in ms | Wandelrate in s ⁻¹ |
|----------|-------|-----------------------------|-------------------------------|
| UINT | 4 | 1 | 1000 |
| | 9 | 2 | 500 |
| | 48 | 10 | 100 |
| | 80 | 16,7 | 60 |
| | 96 | 20 (Bus Controller Default) | 50 |
| | 160 | 33,3 | 30 |
| | 192 | 40 | 25 |
| | 320 | 66,7 | 15 |
| | 480 | 100 | 10 |
| | 960 | 200 | 5 |

Information:

Je geringer die Wandelrate konfiguriert wird, desto genauer kann der Wert gewandelt werden. Allerdings wird dadurch auch die I/O-Updatezeit erhöht.

9.32.8.8.4.2 Operating mode of the A/D converter

Name:

ModeADC

The operating mode for the A/D converter can be configured in this register.

The individual options allow faster digitalization of the analog values, but this also reduces the precision of the measured values.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|--------|--------------------------|-------|---|
| 0 | Chopper mode | 0 | Alternating gain of the analog value (bus controller default setting) |
| | | 1 | Chopper mode off |
| 1 | Order of the SINC filter | 0 | SINC4 (bus controller default setting) |
| | | 1 | SINC3 |
| 2 - 15 | Reserved | - | - |

The following applies:

$$\begin{aligned} \text{ConversionTime(SINC3)} &= \text{ConversionTime(SINC4)} - 1 \times \text{ConversionCycle} \\ \text{ConversionTime(without Chop)} &= 0.5 \times \text{ConversionTime(Chop)} \end{aligned}$$

9.32.8.8.5 Configuring the measurement channels

Each temperature measurement channel can be configured independently. All the registers required for this purpose by each channel are arranged separately.

9.32.8.8.5.1 General channel configuration

Name:

SensorType01 to SensorType02

This register defines the basic behavior of the channel.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 129 |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|------------|--|
| 0 - 2 | Sensor type with unit and resolution | 001 | PT100 [10 mK/bit] - Temperature measurement (bus controller default setting) |
| | | 010 | PT100 [1 mΩ/bit] - Resistance measurement |
| | | 011 to 111 | Reserved |
| 3 - 4 | Reserved | - | |
| 5 | Replacement value strategy | 0 | Replace statically |
| | | 1 | Retain last valid value |
| 6 | Monitoring the user-defined limit values | 0 | Switch off additional limits |
| | | 1 | Switch on additional limits |
| 7 | Channel (on/off) | 0 | Switch off the entire channel |
| | | 1 | Switch on channel (bus controller default setting) |
| 8 - 15 | Reserved | - | |

9.32.8.8.6 Configuring the replacement value strategy

If a measured value is detected that is outside the permitted value range, the behavior of the input register must still remain clearly defined. The module provides the user two different options for this purpose.

Retain last valid value

With this strategy, the determined measured value is stored temporarily for a specific time and written to the input register after a delay. If an invalid measured value is detected, this value and all values that have been stored temporarily are discarded. The last valid input register value is retained. To update the value in the input register, there must be enough valid values stored in the temporary buffer. The number needed is determined by the time period specified in "PreparationInterval0x".

Replace with static value

With this strategy, the measured value is written to the input register without delay. If an invalid value occurs, it is replaced by a static value that has been predefined by the user.

9.32.8.8.6.1 Preparation interval

Name:

PreparationInterval01 to PreparationInterval02

This register defines the time interval in which the measured value is checked before being passed on.

| Data type | Value | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Unit in 0.1 ms. Bus controller default setting: 0 |

Information:

This register only needs to be defined if replacement value strategy "Retain last valid value" was selected in register "SensorType0x" on page 3717.

9.32.8.8.6.2 Static replacement value for upper limit

Name:

ReplaceUpper01 to ReplaceUpper02

This register is used to defined a replacement value that is output in place of the invalid measured value if the upper limit is violated.

| Data type | Values | Information |
|-----------|------------------------------------|---|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 2,147,483,647 |

Information:

This register must be defined if the replacement value strategy "Replace with static value" was selected in register "[SensorType0x](#)" on page 3717.

9.32.8.8.6.3 Static replacement value for lower limit

Name:

ReplaceLower01 to ReplaceLower02

This register is used to defined a replacement value that is output in place of the invalid measured value if the lower limit is violated.

| Data type | Values | Information |
|-----------|------------------------------------|--|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: -2,147,483,647 |

Information:

This register must be defined if the replacement value strategy "Replace with static value" was selected in register "[SensorType0x](#)" on page 3717.

9.32.8.8.7 Configuring the user-defined limit values

This module provides the user the option to specify user-defined limits. If the valid measurement range is reduced in this way, the behavior of the replacement value strategy is more likely to be applied.

Valid measurement range

The valid range is derived from the properties of the sensor being used or the hardware and firmware of the respective B&R module. These values cannot be changed by the user.

Valid range of values

The range of values is always within the valid measurement range. The range of values can be adapted to the requirements of the application by specifying the [upper](#) and [lower](#) limit value.

9.32.8.8.7.1 Upper limit value

Name:

UpperLimit01 to UpperLimit02

This register specifies the upper limit value. The values entered should be within the valid measurement range.

| Data type | Values | Information |
|-----------|------------------------------------|---|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 2,147,483,647 |

9.32.8.8.7.2 Lower limit value

Name:

LowerLimit01 to LowerLimit02

This register specifies the lower limit value. The values entered should be within the valid measurement range.

| Data type | Values | Information |
|-----------|------------------------------------|--|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: -2,147,483,647 |

9.32.8.8.7.3 Hysteresis

Name

Hysteresis01 to Hysteresis02

A hysteresis can be set in order to avoid frequent status changes in the measurement range close to the limit value. Here, a small section is defined at the edge of the valid range of values where the measured values retain the status (valid or invalid) of the previous measured value.

| Data type | Values | Information |
|-----------|-------------|------------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 16 |

9.32.8.8.8 Configuring status messages

Errors are detected by the module and sent to the application. When using Function model 0 - Standard, the trigger behavior of these error messages can be influenced by the "Delay" register.

In Automation Studio, an error message can be read either packed as the entire register or individually as bits.

9.32.8.8.8.1 Delaying error messages

Name:

ErrorDelay01 to ErrorDelay02

In order to avoid false alarms due to short-term measurement variations, the status messages transmitted to the PLC can be delayed. This register determines the number of A/D conversions in which an error must exist before an error message is transmitted.

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | AD conversions. Bus controller default setting: 2 |

9.32.8.8.8.2 Delaying the sum error message

Name:

SumErrorDelay01 to SumErrorDelay02

This register can be used to set the delay used when sending bit 5 of the "Status0x" on page 3721 register to the PLC independent of the other status messages.

| Data type | Values | Information |
|-----------|-------------|--------------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 4000 |

9.32.8.8.9 Communication

The received temperature data is stored with a [timestamp](#) and, depending on the configuration, is made available under various register names and data types.

9.32.8.8.9.1 Measured value – Temperature

Name:

Temperature01 to Temperature02

If the channel is configured for resistance measurement, the current temperature value is made available in this register.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

9.32.8.8.9.2 Measured value – Resistance

Name:

Resistor01 to Resistor02

If the channel is configured for resistance measurement, the current resistance value is made available in this register.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.32.8.8.9.3 Measured value – Unweighted

Name:

Measurand01 to Measurand02

When using the AsloAcc library, the unweighted measurement can be accessed via this register. This refers to a measured value that is within the valid measurement range and has not yet been compared with the user-defined limits.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Information:

If no user-defined limits are configured, the value of this register does not differ from the temperature or resistance value.

9.32.8.8.9.4 Cycle counter

Name:

IOCycleCounter01 to IOCycleCounter02

This register is used to provide a continuous counter for the application that is incremented each time a temperature value is read.

| Data type | Value | Information |
|-----------|-------------|----------------|
| USINT | 0 to 32,767 | AD conversion. |
| UINT | 0 to 65,535 | AD conversion. |

9.32.8.8.9.5 Sampling time - Timestamp

Name:

Sampletime01 to Sampletime02

This register provides the application with the NetTime at the time of temperature recording.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Value | Information |
|-----------|---------------------------------|------------------------------|
| INT | -32,768 to 32,767 | NetTime timestamp in μ s |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime timestamp in μ s |

Information:

The SDC library requires a 16-bit value for the sampling time. It is therefore also prepared as a 16-bit value.

9.32.8.8.9.6 Status messages

Name:

Status01 to Status02

The register bits are set if an error has been diagnosed and the error remains longer than the delay configured in the "ErrorDelay0x" on page 3719 register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|--------------------------------------|-------|--|
| 0 | Underrun01 to Underrun02 | 0 | No error |
| | | 1 | Value below the permitted range |
| 1 | Overrun01 to Overrun02 | 0 | No error |
| | | 1 | Value above the permitted range |
| 2 | OpenLine01 to OpenLine02 | 0 | No error |
| | | 1 | Sensor is not connected correctly |
| 3 | Reserved | - | |
| 4 | ConverterFault01 to ConverterFault02 | 0 | No error |
| | | 1 | Invalid A/D converter output |
| 5 | SumFault01 to SumFault02 | 0 | No error |
| | | 1 | Composite error |
| 6 | ParameterFault01 to ParameterFault02 | 0 | No error |
| | | 1 | The "SensorType0x" on page 3717 register is faulty |
| 7 | IoSupplyFault01 to IoSupplyFault02 | 0 | No error |
| | | 1 | The I/O supply voltage is faulty |

9.32.8.8.9.7 Status messages for function model 254

Name:

Status01To02

The bits in this register are set if an error has been detected.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|------------------------|-------|---------------------------------|
| 0 | Underrun on channel 01 | 0 | No error |
| | | 1 | Value below the permitted range |
| 1 | Overrun on channel 01 | 0 | No error |
| | | 1 | Value above the permitted range |
| 2 | Underrun on channel 02 | 0 | No error |
| | | 1 | Value below the permitted range |
| 3 | Overrun on channel 02 | 0 | No error |
| | | 1 | Value above the permitted range |
| 4 - 7 | Reserved | - | |

Information:

If an open line is detected on a channel, then both error messages will be displayed at the same time.

9.32.8.8.10 NetTime Technology

For a description of NetTime Technology, see "NetTime Technology" on page 3035.

9.32.8.8.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.32.8.8.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

| Minimum I/O update time |
|-------------------------|
| 1 ms |

9.32.9 X20ATA492

Data sheet version: 1.41

9.32.9.1 General information

The module is equipped with 2 inputs for J, K, N, S, B, R, E, C and T thermocouple sensors. The 2 measurement channels are electrically isolated from each other.

This module can also be equipped with the X20TB1E thermocouple terminal block with integrated PT1000 temperature sensors. This makes it possible to achieve optimal terminal temperature compensation.

- Single-channel electrical isolation
- Integrated terminal temperature compensation
- 2x PT1000 sensor integrated in the terminal
- 2x external PT1000 sensor can be connected, 2-wire or 4-wire connections
- NetTime timestamp: Moment of measurement

NetTime timestamp of the measurement

For many applications, not only the measured value is important, but also the exact time of the measurement. The module is equipped with a NetTime timestamp function for this that supplies a timestamp for the recorded position and trigger time with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.32.9.2 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | Temperature measurement |  |
| X20ATA492 | X20 temperature input module, 2 thermocouple inputs, type J, K, N, S, B, R, E, C, T, single-channel isolation, NetTime function, 2x PT1000 integrated in terminal block X20TB1E for temperature compensation, order terminal block separately. | |

9.32.9.4 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-------|--------------------------------|---|
|  | S | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | 1 - 2 | Green | Single flash | A parameter or conversion error has occurred. This status is output in addition to a single/double flash on the channel LED of the analog input where the error occurs. |
| | | | Solid red / Single green flash | Invalid firmware |
| | | | Off | Input turned off or not supplied |
| | | | Single flash | A parameter error has occurred. A single flash is output on the red "s" module status LED. |
| | | | Double flash | A conversion error has occurred. A single flash is output on the red "s" module status LED. |
| | | | Blinking | Overflow, underflow or open line |
| | | | On | Analog/digital converter running, value OK |

- 1) Depending on the configuration, a firmware update can take up to several minutes.

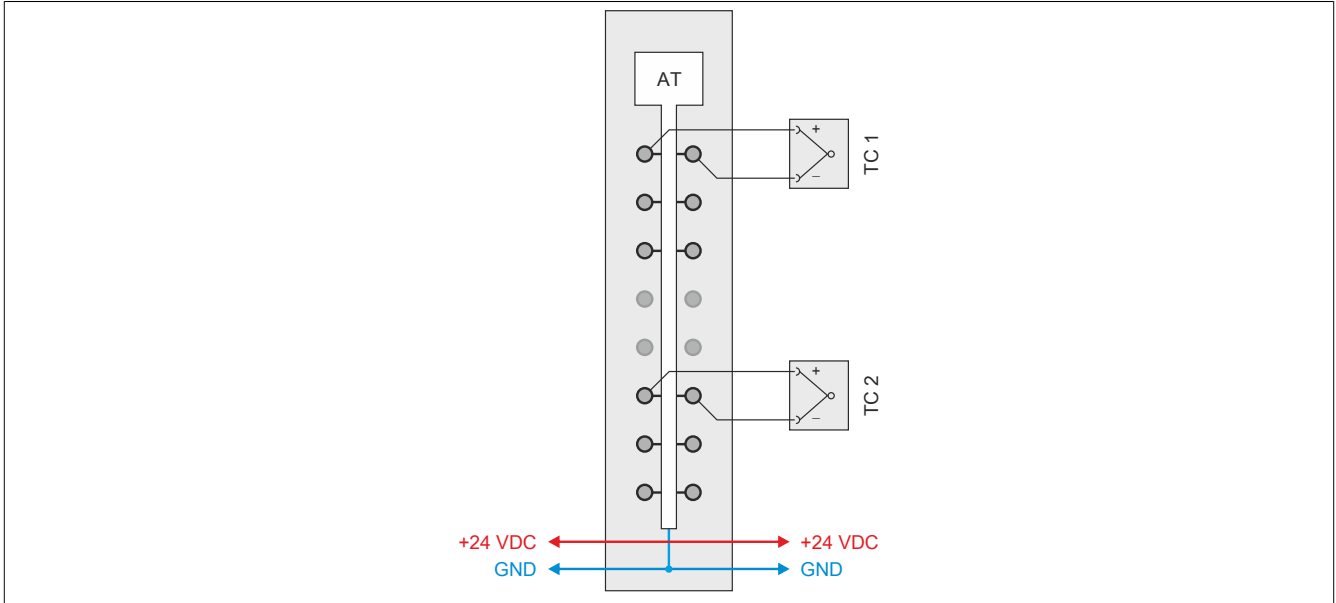

9.32.9.5 Pinout

9.32.9.6 Connection examples

Internal temperature compensation

The thermocouple terminal block X20TB1E with integrated PT1000 sensors is used for internal temperature compensation.

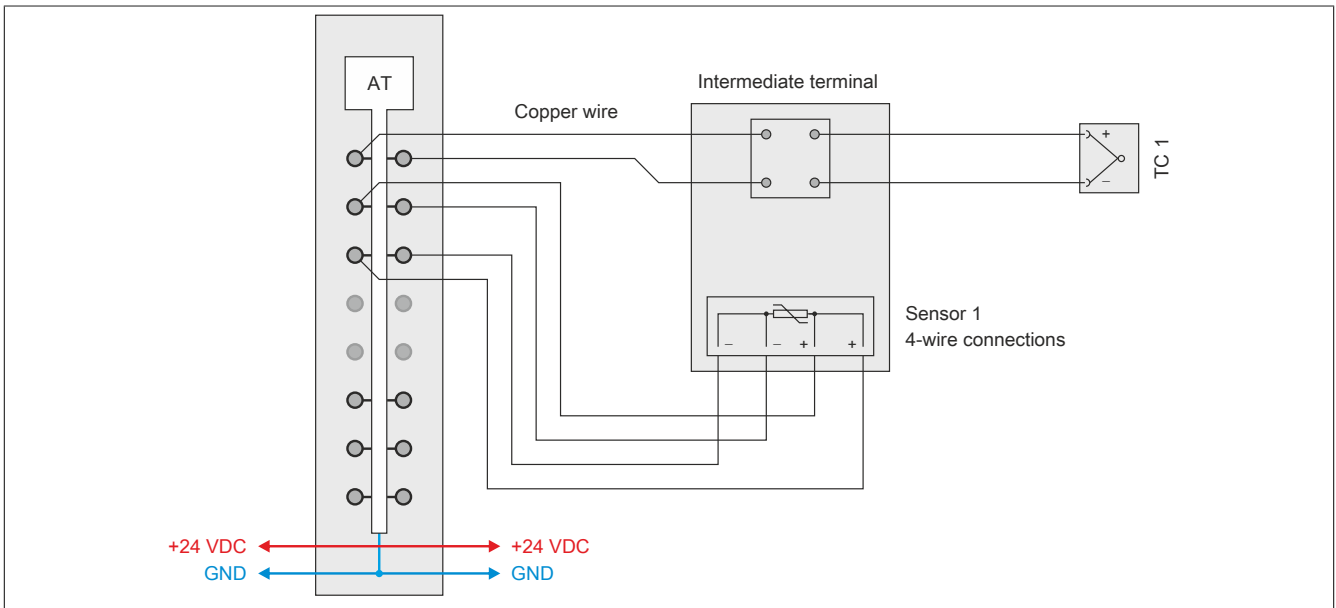

Remote temperature compensation

The 16-pin X20TB1F standard terminal block is used for remote temperature compensation. The external PT1000 sensors are connected to the module using 2-wire or 4-wire connections.

2-wire connections

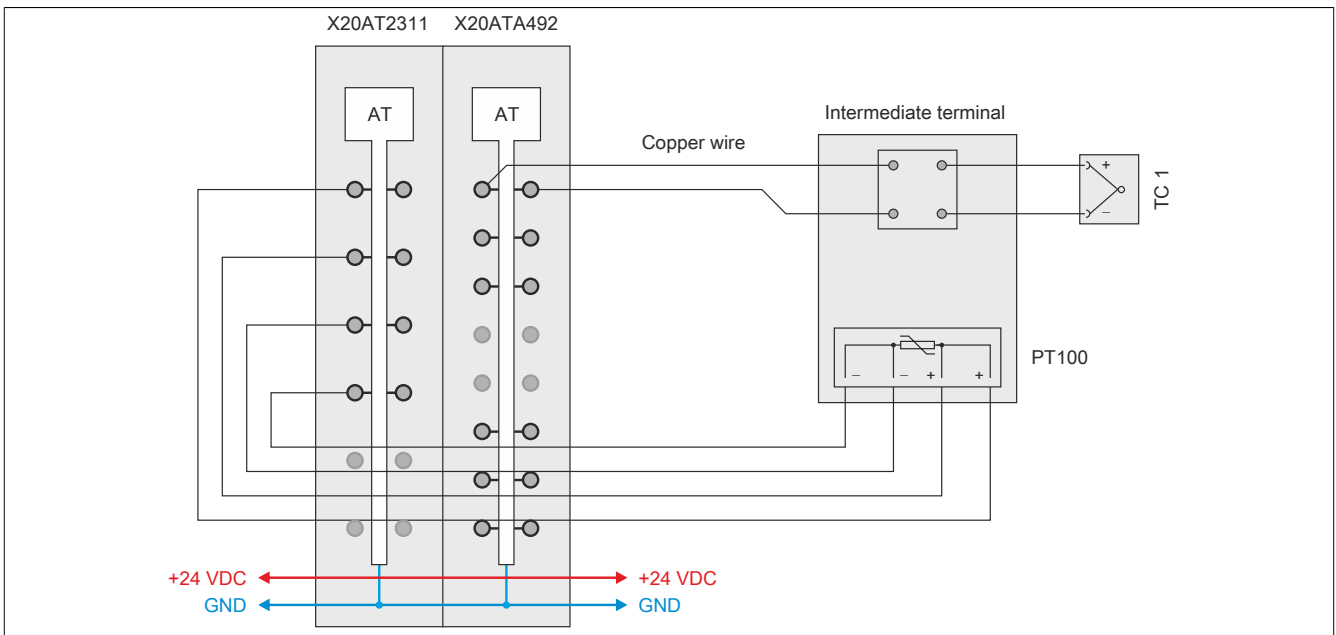

4-wire connections

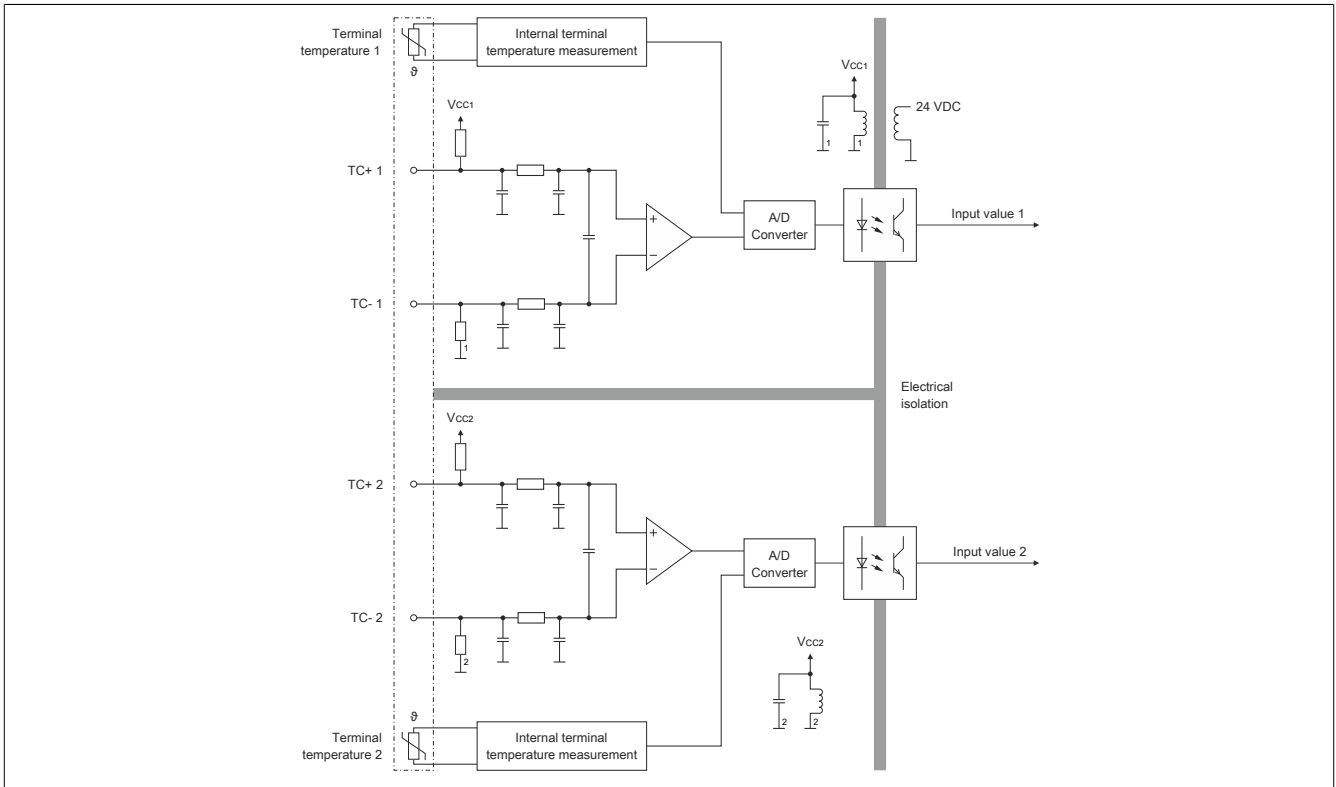

External temperature compensation

External compensation does not require the PT1000 values to be converted internally in the module. Instead, the reference temperatures have to be pre-processed in the program before being stored in the module. A separate register is available for each temperature channel to transfer an externally pre-processed compensation value.

In the following example, the compensation value is determined using the X20AT2311 temperature input module and a PT100 sensor on the intermediate terminal. The cold junction temperature determined externally is then made available to the X20ATA492 module via the respective I/O data points.

9.32.9.7 Input circuit diagram

9.32.9.8 Increased precision

9.32.9.8.1 Internal temperature compensation

When using internal terminal temperature compensation, a temperature model must be defined in order to increase precision. A temperature model should be selected according to the following criteria:

- Thermal power loss of neighboring modules
- X20 system - Mounting orientation

9.32.9.8.1.1 Neighboring modules with low thermal power loss

The temperature model listed in the table must be configured according to the mounting orientation.

| Horizontal installation | Vertical installation | | | | | | | | | | | |

The following temperature model must be set in the "Cfo_SensorTypeCh0x" on page 3736 register.

| Bit 6 and 7 | Temperature model | Bit 6 and 7 | Temperature model |
|-------------|---|-------------|---|
| 00 | Horizontal installation, low thermal radiance <1W | 10 | Vertical installation, low thermal radiance <1W |

Information:

The best results are achieved by placing a dummy module on both sides.

9.32.9.8.1.2 Neighboring modules with higher thermal power loss

The temperature model listed in the table must be configured according to the mounting orientation.

| Horizontal installation | | Vertical installation | |
|--|---|-----------------------|---|
| | | | |
| The following temperature model must be set in the "Cfo_SensorTypeCh0x" on page 3736 register. | | | |
| Bit 6 and 7 | Temperature model | Bit 6 and 7 | Temperature model |
| 01 | Horizontal installation, high thermal radiance >1 W | 11 | Vertical installation, high thermal radiance >1 W |

9.32.9.8.2 Remote or external terminal temperature compensation

Setting up a remote or external cold junction can provide the most accurate temperature measurement in a machine or system.

The installation of a remote or external cold junction is especially helpful in the following cases.

- There is no module next to the temperature module
- With strongly fluctuating environmental conditions (draft, temperature)
- External fan is used in the control cabinet

9.32.9.9 Register description

9.32.9.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.32.9.9.2 Function model 0 - Standard

1) The offset specifies the position of the register within the CAN object.

9.32.9.9.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.32.9.9.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.32.9.9.4 Module configuration

The module is an I/O module for temperature measurement and requires a 16-pin standard terminal block or the 16-pin terminal block with 2 integrated PT1000 inputs for temperature compensation.

2 measuring resistors (PT1000) can be connected via pin pairs 12/22 and 17/27 to record the absolute compensation temperature. This comparative value is used as a reference for the actual temperature measurement.

9.32.9.9.4.1 Input filter

Name:

Cfo_InputFilterCh01 bis Cfo_InputFilterCh02

Mit Hilfe dieser Register wird die Abtastzeit des A/D-Wandlers konfiguriert. Die eingestellte Filter-/Abtastzeit gilt gleichermaßen für die Eingänge der Thermoelemente als auch des Temperaturwiderstandes.

| Datentyp | Werte | Filterzeit in ms | Wandelrate in s ⁻¹ |
|----------|-------|-----------------------------|-------------------------------|
| UINT | 4 | 1 | 1000 |
| | 9 | 2 | 500 |
| | 48 | 10 | 100 |
| | 80 | 16,7 | 60 |
| | 96 | 20 (Bus Controller Default) | 50 |
| | 160 | 33,3 | 30 |
| | 192 | 40 | 25 |
| | 320 | 66,7 | 15 |
| | 480 | 100 | 10 |
| | 960 | 200 | 5 |

Information:

Je geringer die Wandelrate konfiguriert wird, desto genauer kann der Wert gewandelt werden. Allerdings wird dadurch auch die I/O-Updatezeit erhöht.

9.32.9.9.5 Compensation

The measurement process is based on the interaction between the temperature sensors and the thermocouples. The converted voltage value of a thermocouple has a linear relationship with the difference in temperature between the measurement point and the transition point. To calculate the absolute temperature at the measurement point, the measured value must then be placed in relation to an absolute reference temperature.

The compensation value required for this can be determined as follows:

- Value determined directly on the module using a PT1000 temperature sensor. ("[Internal compensation](#)" on page 3734)
- Value provided via a cyclic data point. ("[External compensation](#)" on page 3736)

9.32.9.9.5.1 Internal compensation

The inputs of the temperature resistors are used for internal compensation. The module can be used with the 16-pin terminal block (X20TB1E), which has 2 PT1000 temperature sensors.

When operating the module with the X20TB1E, the temperature distribution on the terminal block must be taken into account. To do this, various models for calculating the temperature distribution have been implemented on the module. They account for both the ambient temperature in the control cabinet, as well as the mounting orientation of the module. This helps minimize measurement error.

Alternatively, the module can be operated with the standard 16-pin terminal block (X20TB1F). For a detailed description of this procedure, see "[Remote terminal block](#)" on page 3735.

Information:

To avoid unnecessary traffic on the X2X Link network, the compensation registers should only be transferred cyclically during the fine-tuning process and for service and maintenance purposes. The information is generally not required during normal operation.

Compensation value

Name:

CompensationValue01 to CompensationValue02

These registers can be used to read the compensation value. Depending on how the "[Cfo_SensorType](#)" on page 3736 register is set, it is output as either a temperature or resistance value.

| Data type | Value | Information |
|-----------|-----------------|-------------------|
| INT | -32767 to 32767 | in 0.1°C or 0.1 Ω |

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is switched off, 0x8000 is output.
- If an I/O voltage supply failure occurs, 0x8001 is output.

Status of the compensation value

Name:

CompensationStatus01 to CompensationStatus02
 CompUnderflow01 to CompUnderflow02
 CompOverflow01 to CompOverflow02
 CompOpenLine01 to CompOpenLine02
 CompConversionError01 to CompConversionError02
 CompSumError01 to CompSumError02
 CompParameterError01 to CompParameterError02
 ComploSuppError01 to ComploSuppError02

These registers provide information about the current status of the respective compensation value. The structure is based on the "StatusInput" on page 3740 register.

| Data type | Value |
|-----------|-------------------|
| USINT | See bit structure |

Bit structure:

| Bit | Name | Value | Information |
|-----|-----------------------|-------|---------------------------------|
| 0 | CompUnderflow0x | 0 | No error |
| | | 1 | Value below the permitted range |
| 1 | CompOverflow0x | 0 | No error |
| | | 1 | Value above the permitted range |
| 2 | CompOpenLine0x | 0 | No error |
| | | 1 | Open line |
| 3 | Reserved | - | |
| 4 | CompConversionError0x | 0 | No error |
| | | 1 | Conversion error |
| 5 | CompSumError0x | 0 | No error |
| | | 1 | Composite error (undelayed) |
| 6 | CompParameterError0x | 0 | No error |
| | | 1 | Configuration not permitted |
| 7 | ComploSuppError0x | 0 | No error |
| | | 1 | I/O power supply error |

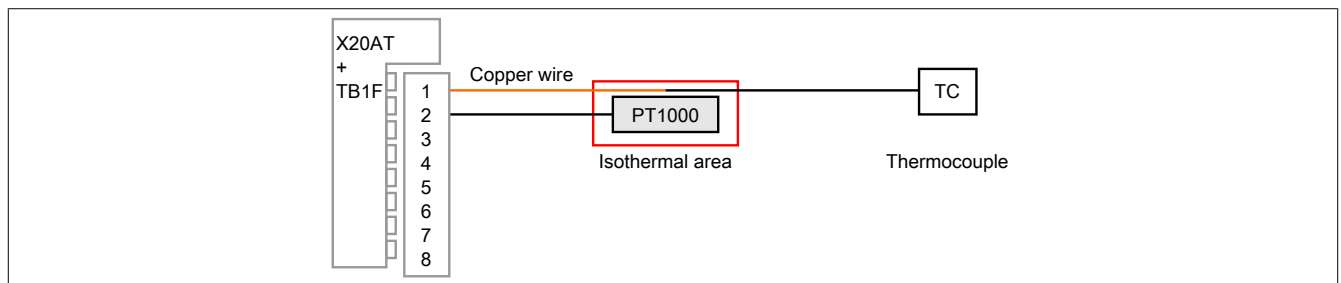

In addition to the status info, the error type also sets the analog value as follows:

| Error status | Digital value for error |
|---|-------------------------|
| Open line | 32767 (0x7FFF) |
| Above upper limit value | 32767 (0x7FFF) |
| Below lower limit value | -32767 (0x8001) |
| Invalid value or I/O power supply error | -32767 (0x8001) |

Remote terminal block

The 16-pin standard terminal block (X20TB1F) is used. The reference point for temperature measurements can be moved from the terminal to a more thermally stable location. This can help to minimize measurement error and increase accuracy.

Principle of remote terminal block

The thermocouple provides $V_{(\Delta T)}$ between the end of the thermocouple and the transition to the copper wire.

The PT1000 sensor provides the absolute temperature of the isothermal area.

Calculation: $T(\text{TC}) = T(\text{PT1000}) + \Delta T$

9.32.9.9.5.2 External compensation

For external compensation, the reference temperatures must be prepared in the application and transferred to the module via X2X Link. There is no need for internal conversion of the PT1000 values in the module.

External compensation value

Name:

ExternalCompensationTemperature01 to ExternalCompensationTemperature02

These registers can be used to send an externally generated compensation value to the module.

| Data type | Value | Information |
|-----------|-----------------|-------------|
| INT | -32767 to 32767 | in 0.1°C |

9.32.9.9.6 Temperature measurement - Configuration

The temperature measurement channels can be configured independently of each other. The "[Cfo_SensorTypeCh](#)" on page 3736 register needs to be adjusted in order to enable a temperature channel. The rest of the registers complement this configuration and only need to be defined if required in the application.

9.32.9.9.6.1 Configuring temperature measurement

Name:

Cfo_SensorTypeCh01 to Cfo_SensorTypeCh02

These registers control the basic functionality of a temperature channel.

| Data type | Value | Information |
|-----------|-------------------|---------------------------------------|
| UINT | See bit structure | Bus controller default setting: 36864 |

Bit structure:

| Bit | Name | Value | Information |
|-------|--|----------|--|
| 0 - 5 | Sensor type | 0 | Sensor J (Fe-CuNi) (bus controller default setting) |
| | | 1 | Sensor K (NiCr-Ni) |
| | | 2 | Sensor N (NiCrSi-NiSi) |
| | | 3 | Sensor S (PtRh10-Pt) |
| | | 4 | Sensor R (PtRh13-Pt) |
| | | 5 | Sensor C (WRe5-WRe26) |
| | | 6 | Sensor T (Cu-CuNi) |
| | | 7 | Sensor B (PtRh30-PtRh6) |
| | | 8 | Sensor E (NiCr-CuNi) |
| | | 9 to 60 | Reserved |
| 6 - 7 | Temperature model for X20TB1E ¹⁾ | 00 | Horizontal mounting orientation, low thermal radiation ≤1 W (bus controller default setting) |
| | | 01 | Horizontal installation, high thermal radiance >1 W |
| | | 10 | Vertical installation, low thermal radiance ≤1W |
| 8 - 9 | Reference method | 11 | Vertical installation, high thermal radiance >1 W |
| | | 00 | PT1000 sensor (bus controller default setting) |
| | | 01 to 10 | Not permitted |
| 10 | Unit for cold junction value | 11 | External compensation |
| | | 0 | 0.1°C (bus controller default setting) |
| 11 | Method of compensation | 1 | 0.1 Ω |
| | | 0 | Internal compensation (bus controller default setting) |
| 12 | Temperature model for X20TB1E ²⁾ | 1 | External compensation |
| | | 0 | Disabled |
| 13 | Replacement value strategy | 1 | Enabled according to bits 6 and 7 (bus controller default setting) |
| | | 0 | Replace with static default value (bus controller default setting) |
| 14 | Additional user-defined limits for permitted range of values | 1 | Retain last valid value |
| | | 0 | Permissible range of values of the thermocouple (bus controller default setting) |
| 15 | Temperature channel | 1 | Range of values as configured ³⁾ |
| | | 0 | Channel not converted by the AD converter |
| | | 1 | Channel registered on the AD converter (bus controller default setting) |

- 1) This setting is used to adjust the internal terminal temperature characteristic curve to the type and amount of generated heat dissipated to the module. This selection is based on the power consumption of the modules connected immediately to the left and right on the X2X Link. This data can be found in the modules' data sheet. The higher value is used for the configuration.
- 2) To enable the temperature model, both PT1000 cold junction sensors must be connected.
- 3) The user-defined limit values can further reduce the permitted range of values for the sensor, depending on the requirements of the application. It is not permitted to define a measurement range larger than the range supported by the sensor.

9.32.9.9.6.2 Defining the preparation interval

Name:

Cfo_PreparationInterval01 to Cfo_PreparationInterval02

If the last valid measured value should be kept when violating the limit value, then PreparationInterval must be defined. The measured values continue to be acquired and converted according to the configured I/O update time. They are then checked and discarded if they do not meet the specifications. When an error does not occur, therefore, the measured value acquired 2 preparation intervals ago is constantly output.

| Data type | Value | Information |
|-----------|------------|---|
| UINT | 0 to 65535 | In 0.1 ms. Bus controller default setting: 0 |

| | |
|--|--|
| <p>Functionality: Measured values are continuously converted and stored to measured value memory depending on the configured input filter. The current contents of the measured value memory are checked within the configured interval. If a permissible value is present, then the contents of the buffer memory are passed to output memory and the contents of the measured value memory are passed to the buffer. If the check turns up an impermissible value, then the contents of the measured value memory are discarded. The copy direction between the output and buffer memory reverses and the last valid value continues to be output.</p> <p>Information: If configured to keep the last valid value, the delay time from measuring to outputting the value will be at least twice the preparation interval. In the worst case scenario, this can also take twice the interval time plus the configured conversion rate of the A/D converter.</p> | <p>"Application" Value being measured (analog)</p> |
| | <p>↓ Condition: - Conversion interval (A/D converter) elapsed</p> |
| | <p>"Measured value memory" Measured value (digital)</p> |
| | <p>↓ Condition: - PreparationInterval elapsed - Measured value permissible</p> |
| | <p>"Buffer" Last valid value</p> |
| <p>↓ Condition: - PreparationInterval elapsed - Measured value permissible</p> | |
| <p>"Output memory" Next-to-last valid/ displayed value</p> | |

Information:

The registers are only set for the channel when bit 13 is set in the "Cfo_SensorType" on page 3736 register.

9.32.9.9.6.3 Upper replacement value

Name:

Cfo_ReplaceUpper01 to Cfo_ReplaceUpper02

This register is used to define the static values to be displayed instead of the current measured value when the limit is violated.

| Data type | Value | Information |
|-----------|-----------------|---------------------------------------|
| INT | -32767 to 32767 | Bus controller default setting: 32767 |

Information:

The registers are only set for the channel when bit 13 is not set in the "Cfo_SensorType" on page 3736 register.

9.32.9.9.6.4 Lower replacement value

Name:

Cfo_ReplaceLower01 to Cfo_ReplaceLower02

This register is used to define the lower static values to be displayed instead of the current measured value when the limit is violated.

| Data type | Value | Information |
|-----------|-----------------|--|
| INT | -32767 to 32767 | Bus controller default setting: -32767 |

Information:

The registers are only set for the channel when bit 13 is not set in the "Cfo_SensorType" on page 3736 register.

9.32.9.9.6.5 Lower limit value

Name:

Cfo_UpperLimit01 to Cfo_UpperLimit02

If the value range needs to be restricted further, these registers can be used to enter new user-specific upper limit values.

| Data type | Value | Information |
|-----------|-----------------|---------------------------------------|
| INT | -32767 to 32767 | Bus controller default setting: 32767 |

9.32.9.9.6.6 Upper limit value

Name:

Cfo_LowerLimit01 to Cfo_LowerLimit02

If the value range needs to be restricted further, these registers can be used to enter new user-specific lower limit values.

| Data type | Value | Information |
|-----------|-----------------|--|
| INT | -32767 to 32767 | Bus controller default setting: -32767 |

9.32.9.9.6.7 Hysteresis

Name:

Cfo_Hysteresis01 to Cfo_Hysteresis02

If the user-specific limit values are being used, then a hysteresis range should also be defined. These registers configure how far a limit value can be exceeded before a response is triggered.

| Data type | Value | Information |
|-----------|-----------------|------------------------------------|
| INT | -32767 to 32767 | Bus controller default setting: 16 |

9.32.9.9.6.8 Error delay

Name:

Cfo_ErrorDelay01 to Cfo_ErrorDelay02

This register specifies the number of consecutive conversion procedures where an error is pending until the corresponding individual error status bit is set. The delay applies to underflow, overflow and open circuit errors. This delay can be used to hide temporary measured value deviations, for example.

| Data type | Values | Information |
|-----------|-------------|-----------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 2 |

9.32.9.9.6.9 Error delay for composite error bit

Name:

Cfo_SumErrorDelay01 to Cfo_SumErrorDelay02

These registers can be used to set the time that an error must remain pending before the composite error bit is set.

| Data type | Values | Information |
|-----------|-------------|--------------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 4000 |

9.32.9.9.7 Temperature measurement

The received temperature data is prepared in 2 different formats and given a [timestamp](#). For each channel there are 2 separate registers for transmitting the measured values to the PLC.

9.32.9.9.7.1 Temperature measurements

Name:

Temperature01 to Temperature02

Measurand01 to Measurand02

These registers contain the analog input values according to the sensor type set in the "[Cfo_SensorType](#)" on page 3736 register:

| Data type | Value | Information | Sensor type |
|------------------|--|---|-----------------------|
| INT | -2,100 to 12,000 | (for -210.0 to 1200.0 °C) | Type J (Fe-CuNi) |
| | -2,700 to 13,720 | (for -270.0 to 1372.0 °C) | Type K (NiCr-Ni) |
| | -2,700 to 12,980 | (for -270.0 to 1298.0 °C) | Type N (NiCrSi-NiSi) |
| | -500 to 17,680 | (for -50.0 to 1768.0 °C) | Type S (PtRh10-Pt) |
| | -500 to 17,600 | (for -50.0 to 1760.0 °C) | Type R (PtRh13-Pt) |
| | 0 to 23,100 | (for 0 to 2310.0 °C) | Type C (WRe5-WRe26) |
| | -2,700 to 4,000 | (for -270.0 to 400.0 °C) | Type T (Cu-CuNi) |
| | 0 to 18,200 | (for 0 to 1820.0 °C) | Type B (PtRh30-PtRh6) |
| | -2,700 to 9,970 | (for -270.0 to 997.0 °C) | Type E (NiCr-CuNi) |
| | -32,768 to 32767 | Voltage without linearization and terminal temperature compensation Resolution 1.0625 µV for a measurement range of ±35 mV | |
| -32,768 to 32767 | Voltage without linearization and terminal temperature compensation Resolution 2.125 µV for a measurement range of ±70 mV | | |

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is switched off, 0x8000 is output.
- If an I/O voltage supply failure occurs, 0x8001 is output.

9.32.9.9.7.2 Sample time

Name:

SampleTime01 to SampleTime02

These registers return the timestamp for when the module reads the current channel mapping. The values are provided as signed 2-byte or 4-byte values.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values | Information |
|-----------|---------------------------|--|
| INT | -32,768 to 32767 | NetTime timestamp of the current input value in µs |
| DINT | -2147483648 to 2147483647 | NetTime timestamp of the current input value in µs |

9.32.9.9.7.3 I/O cycle counter

Name:

IOCycleCount01 to IOCycleCount02

This register is a cyclic counter that is incremented each time a value is converted. It can be used as either a 1-byte or 2-byte counter.

| Data type | Value |
|-----------|------------|
| USINT | 0 to 255 |
| UINT | 0 to 65535 |

9.32.9.9.7.4 Status messages

Name:

StatusInput01 to StatusInput02

Underflow01 to Underflow02

Overflow01 to Overflow02

OpenLine01 to OpenLine02

CompTemperaturError01 to CompTemperaturError02

ConversionError01 to ConversionError02

SumError01 to SumError02

ParameterError01 to ParameterError02

IoSuppError01 to IoSuppError02

The current error status of the module channels is displayed in these registers, regardless of the configured replacement value strategy. Some error information may be delayed according to the conditions configured previously in the "Cfo_ErrorDelay" on page 3738 and "Cfo_SumErrorDelay" on page 3738 registers.

| Data type | Value |
|-----------|--------------------|
| USINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|-----------------------------|-------|---|
| 0 | Underflow0x | 0 | No error |
| | | 1 | Value below the permitted range |
| 1 | Overflow0x | 0 | No error |
| | | 1 | Value above the permitted range |
| 2 | OpenLine0x | 0 | No error |
| | | 1 | Open line |
| 3 | CompTemperaturError0x | 0 | Reference temperature is OK |
| | | 1 | Compensation error; See "CompensationStatus" on page 3735 register for a detailed error description |
| 4 | ConversionError0x | 0 | No error |
| | | 1 | Converter error |
| 5 | SumError0x | 0 | No error |
| | | 1 | Undelayed composite error |
| 6 | ParameterError0x | 0 | No error |
| | | 1 | Invalid setting for "Cfo_SensorType" on page 3736 register |
| 7 | IoSuppError0x ¹⁾ | 0 | No error |
| | | 1 | I/O power supply error |

1) If the supply falls below 20 VDC, then the I/O power supply error is reported in these bits for the respective temperature channel. The following actions also take place:

- Channel LEDs are turned off
- Temperature values are set to an invalid value = 0x8001
- "IOCycleCount" on page 3739 and "SampleTime" on page 3739 stop changing

In addition to the status information, the analog value is permanently defined to the following value in an error state:

| Fehlerzustand | Digital value for error |
|--|-------------------------|
| Drahtbruch | 32767 (0x7FFF) |
| Above upper limit value | 32767 (0x7FFF) |
| Unterer Grenzwert unterschritten | -32767 (0x8001) |
| Ungültiger Wert oder I/O-Versorgungsfehler | -32767 (0x8001) |

9.32.9.9.8 NetTime Technology

For a description of NetTime Technology, see "NetTime Technology" on page 3035.

9.32.9.9.9 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.32.9.9.10 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

The A/D converter must convert multiple values. After switching between 2 inputs there are 4 measurements in order to obtain a meaningful value. Since not all inputs need to be used, the actual I/O update time may vary.

The following formulas can be used to calculate the minimum required I/O update time:

$$\text{I/O update time} = 4 * \text{Conversions} * \text{Filter time}$$

$$\text{Filter time} = (1024 / 4920000) * C_{fo_InputFilter}$$

$$\text{Conversions} = \text{Number of thermocouples} + \text{Number of temperature resistors}$$

9.32.10 X20ATB312

Data sheet version: 1.43

9.32.10.1 General information

The module is equipped with 4 inputs for PT100 4-line resistance temperature measurement.

- 4 inputs for resistance temperature measurement
- PT100 sensor
- Direct resistance measurement as well
- 4-wire measurement
- Filter time can be configured
- NetTime timestamp: Moment of measurement

NetTime timestamp of the measurement

For many applications, not only the measured value is important, but also the exact time of the measurement. The module is equipped with a NetTime timestamp function for this that supplies a timestamp for the recorded position and trigger time with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.32.10.2 Order data

| Model number | Short description | Figure |
|--------------|---|--|
| X20ATB312 | X20 temperature input module, 4 inputs for resistance measurement, PT100, resolution 0.01°C, 4-wire connections, NetTime function |  |

Table 652: X20ATB312 - Technical data

- 1) The module is equipped with two independent converters (sensors 1 and 2, sensors 3 and 4). The conversion time applies to the number of channels connected to the respective converter.
- 2) To guarantee accuracy, modules with a power dissipation < 1.2 W must be connected to the left and right of this module.
- 3) Based on the current resistance value.
- 4) Based on the entire resistance measurement range.

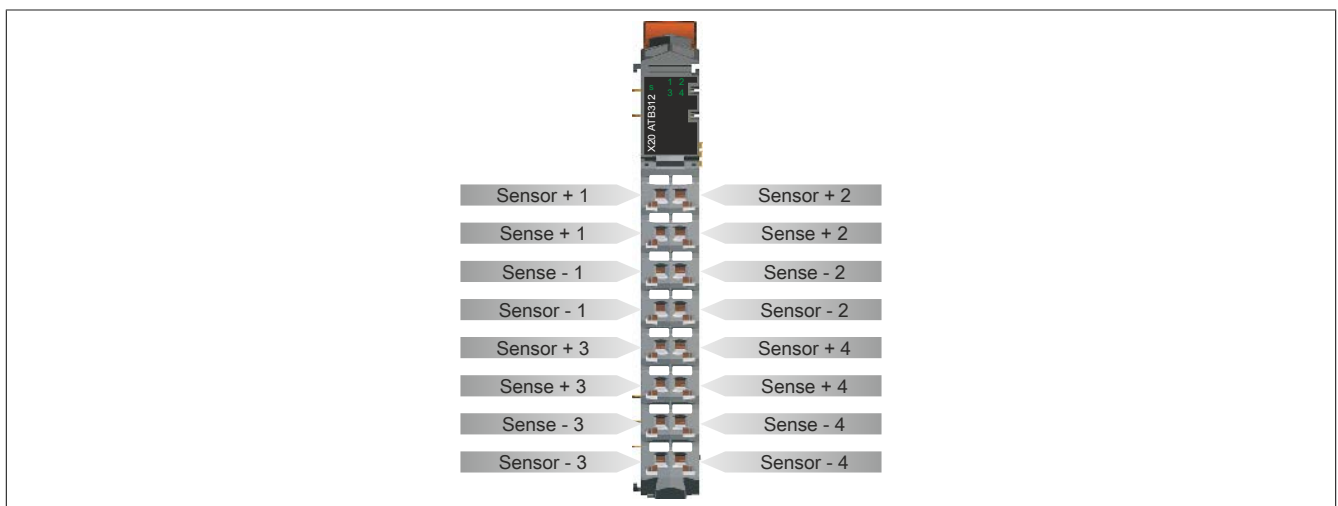

9.32.10.4 Status LEDs

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

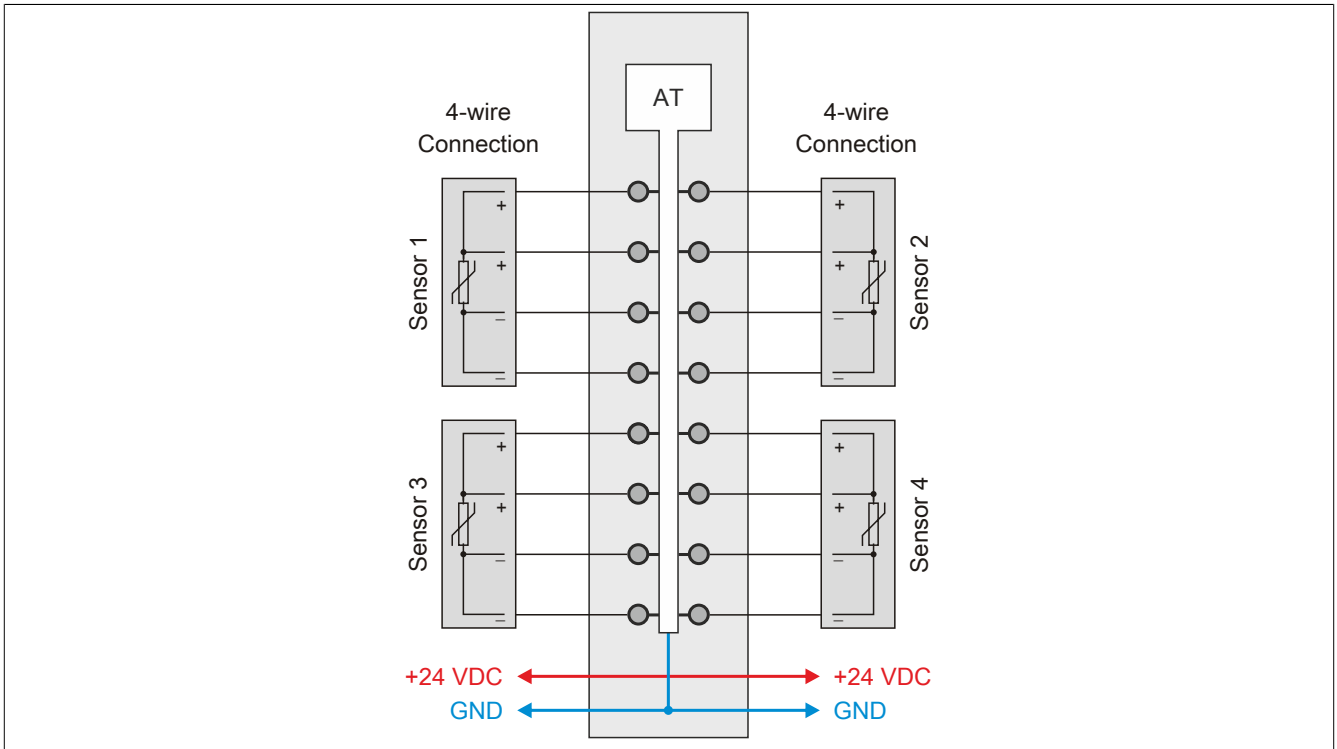

| Image | LED | Color | Status | Description |
|---|-------|-------|-----------------------------|--|
|  | s | Green | Off | Module supply not connected |
| | | | Single flash | Reset mode |
| | | | Double flash | Mode BOOT (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | | Red | Off | Module supply not connected or everything OK |
| | On | | Error or reset status | |
| | 1 - 4 | Green | Single flash | Parameter or conversion error ²⁾ |
| | | | Red on / Green single flash | Invalid firmware |
| | | | Off | Input turned off or not supplied |
| | | | Single flash | Parameter error ²⁾ |
| | | | Double flash | Conversion error ²⁾ |
| | | | Blinking | Overflow, underflow or open line |
| | | | On | A/D converter running, value OK |

- 1) Depending on the configuration, a firmware update can take up to several minutes.
- 2) Parameter or converter errors are indicated simultaneously on the red "s" LED and the channel LED of the respective output.

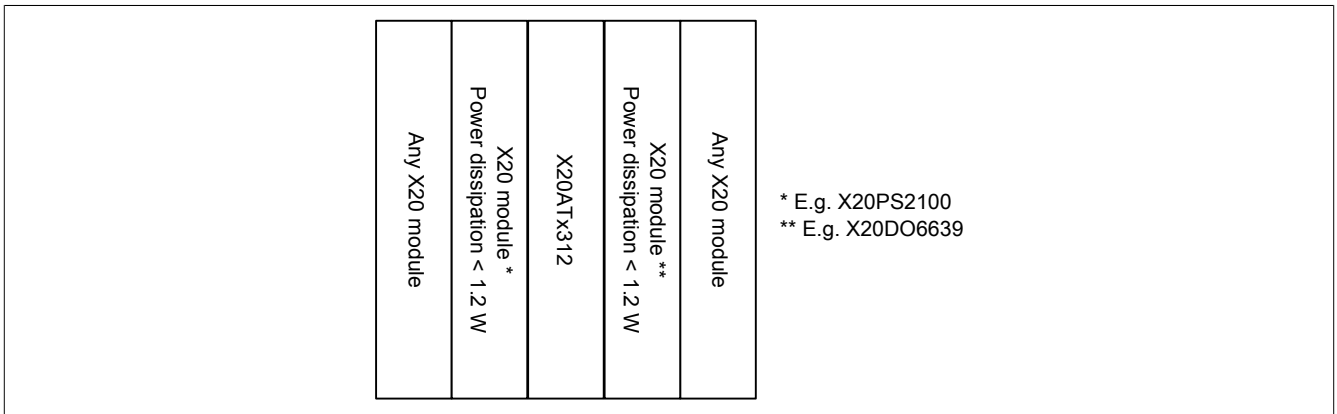

9.32.10.5 Pinout

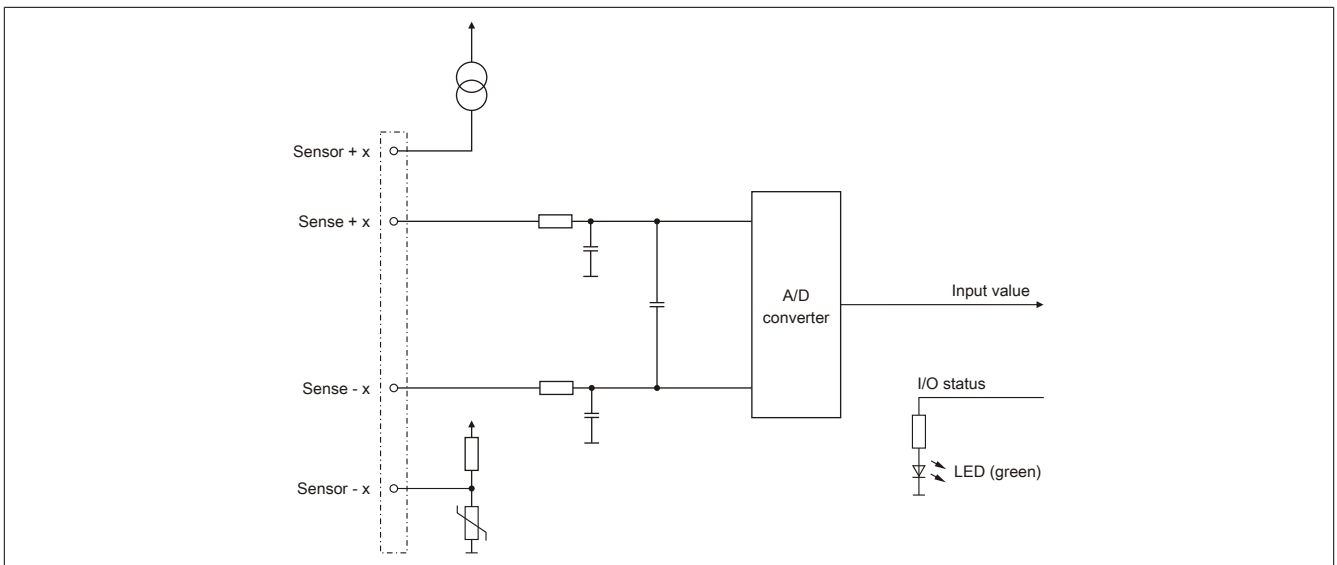

9.32.10.6 Connection example

To ensure accuracy, modules with a power consumption <math>< 1.2\text{ W}</math> must be inserted to the left and right of this modules.

9.32.10.7 Input circuit diagram

9.32.10.8 Register description

9.32.10.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.32.10.8.2 Function model 0 - Standard

| Register | Name | Data type | Read | | Write | |
|---------------------|--|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |
| 130 | InputFilter | UINT | | | | • |
| 134 | ModeADC | UINT | | | | • |
| Index * 64 + 450 | SensorType0x (Index x = 1 to 4) | UINT | | | | • |
| Index * 64 + 502 | PreparationInterval0x (Index x = 1 to 4) | UINT | | | | • |
| Index * 64 + 484 | ReplaceUpper0x (Index x = 1 to 4) | DINT | | | | • |
| Index * 64 + 476 | ReplaceLower0x (Index x = 1 to 4) | DINT | | | | • |
| Index * 64 + 468 | UpperLimit0x (Index x = 1 to 4) | DINT | | | | • |
| Index * 64 + 460 | LowerLimit0x (Index x = 1 to 4) | DINT | | | | • |
| Index * 64 + 490 | Hysteresis0x (Index x = 1 to 4) | UINT | | | | • |
| Index * 64 + 494 | ErrorDelay0x (Index x = 1 to 4) | UINT | | | | • |
| Index * 64 + 498 | SumErrorDelay0x (Index x = 1 to 4) | UINT | | | | • |
| Communication | | | | | | |
| Index * 4 - 4 | Temperature0x (Index x = 1 to 4) | DINT | • | | | |

| | ConverterFault0x | Bit 4 | | | | |
| | SumFault0x | Bit 5 | | | | |
| | ParameterFault0x | Bit 6 | | | | |
| | IoSupplyFault0x | Bit 7 | | | | |

9.32.10.8.3 Function model 254 - Bus Controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------------------|----------------------|--|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | | |
| 130 | - | InputFilter | UINT | | | | • |
| 134 | - | ModeADC | UINT | | | | • |
| Index * 64 + 450 | - | SensorType0x (Index x = 1 to 4) | UINT | | | | • |
| Index * 64 + 502 | - | PreparationInterval0x (Index x = 1 to 4) | UINT | | | | • |
| Index * 64 + 484 | - | ReplaceUpper0x (Index x = 1 to 4) | DINT | | | | • |
| Index * 64 + 476 | - | ReplaceLower0x (Index x = 1 to 4) | DINT | | | | • |
| Index * 64 + 468 | - | UpperLimit0x (Index x = 1 to 4) | DINT | | | | • |
| Index * 64 + 460 | - | LowerLimit0x (Index x = 1 to 4) | DINT | | | | • |
| Index * 64 + 490 | - | Hysteresis0x (Index x = 1 to 4) | UINT | | | | • |
| Index * 64 + 494 | - | ErrorDelay0x (Index x = 1 to 4) | UINT | | | | • |
| Index * 64 + 498 | - | SumErrorDelay0x (Index x = 1 to 4) | UINT | | | | • |
| Communication | | | | | | | |
| Index * 4 - 4 | Index * 4 - 4 | Temperature0x (Index x = 1 to 4) | DINT | • | | | |
| | | Resistor0x (Index x = 1 to 4) | UDINT | | | | |
| Index * 64 + 217 | - | IOCycleCounter0x (Index x = 1 to 4) | USINT | | • | | |
| 30 | - | Status01To04 | USINT | | • | | |

1) The offset specifies where the register is within the CAN object.

9.32.10.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.32.10.8.3.2 CAN I/O bus controller

The module occupies the following analog logical slots on CAN I/O.

- Upgrade version <1.1.3.0: 1
- Upgrade version ≥1.1.3.0: 2

9.32.10.8.4 Configuration of the A/D converter

9.32.10.8.4.1 Setting the conversion rate

Name:

InputFilter

Mit Hilfe dieses Registers wird die Abtastzeit des A/D-Wandlers konfiguriert.

| Datentyp | Werte | Filterzeit in ms | Wandelrate in s ⁻¹ |
|----------|-------|-----------------------------|-------------------------------|
| UINT | 4 | 1 | 1000 |
| | 9 | 2 | 500 |
| | 48 | 10 | 100 |
| | 80 | 16,7 | 60 |
| | 96 | 20 (Bus Controller Default) | 50 |
| | 160 | 33,3 | 30 |
| | 192 | 40 | 25 |
| | 320 | 66,7 | 15 |
| | 480 | 100 | 10 |
| | 960 | 200 | 5 |

Information:

Je geringer die Wandelrate konfiguriert wird, desto genauer kann der Wert gewandelt werden. Allerdings wird dadurch auch die I/O-Updatezeit erhöht.

9.32.10.8.4.2 Operating mode of the A/D converter

Name:

ModeADC

The operating mode for the A/D converter can be configured in this register.

The individual options allow faster digitalization of the analog values, but this also reduces the precision of the measured values.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|--------|--------------------------|-------|---|
| 0 | Chopper mode | 0 | Alternating gain of the analog value (bus controller default setting) |
| | | 1 | Chopper mode off |
| 1 | Order of the SINC filter | 0 | SINC4 (bus controller default setting) |
| | | 1 | SINC3 |
| 2 - 15 | Reserved | - | - |

The following applies:

$$\text{ConversionTime(SINC3)} = \text{ConversionTime(SINC4)} - 1 \times \text{ConversionCycle}$$

$$\text{ConversionTime(without Chop)} = 0.5 \times \text{ConversionTime(Chop)}$$

9.32.10.8.5 Configuring the measurement channels

Each temperature measurement channel can be configured independently. All the registers required for this purpose by each channel are arranged separately.

9.32.10.8.5.1 Channel parameters

Name:

SensorType01 to SensorType04

This register defines the basic behavior of the channel.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 129 |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|------------|--|
| 0 - 2 | Sensor type with unit and resolution | 001 | PT100 [10 mK/bit] - Temperature measurement (bus controller default setting) |
| | | 010 | PT100 [1 mΩ/bit] - Resistance measurement |
| | | 011 to 111 | Reserved |
| 3 - 4 | Reserved | - | |
| 5 | Replacement value strategy | 0 | Replace statically |
| | | 1 | Retain last valid value |
| 6 | Monitoring the user-defined limit values | 0 | Switch off additional limits |
| | | 1 | Switch on additional limits |
| 7 | Channel (on/off) | 0 | Switch off the entire channel |
| | | 1 | Switch on channel (bus controller default setting) |
| 8 - 15 | Reserved | - | |

9.32.10.8.6 Configuring the replacement value strategy

If a measured value is detected that is outside the permitted value range, the behavior of the input register must still remain clearly defined. The module provides the user two different options for this purpose.

Retain last valid value

With this strategy, the determined measured value is stored temporarily for a specific time and written to the input register after a delay. If an invalid measured value is detected, this value and all values that have been stored temporarily are discarded. The last valid input register value is retained. To update the value in the input register, there must be enough valid values stored in the temporary buffer. The number needed is determined by the time period specified in "PreparationInterval0x".

Replace with static value

With this strategy, the measured value is written to the input register without delay. If an invalid value occurs, it is replaced by a static value that has been predefined by the user.

9.32.10.8.6.1 Preparation interval

Name:

PreparationInterval01 to PreparationInterval04

This register defines the time interval in which the measured value is checked before being passed on.

| Data type | Value | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Unit in 0.1 ms. Bus controller default setting: 0 |

Information:

This register must be defined if the replacement value strategy "Retain last valid value" was selected in register "SensorType0x" on page 3749.

9.32.10.8.6.2 Static replacement value when exceeding the upper limit

Name:

ReplaceUpper01 to ReplaceUpper04

This register is used to defined a replacement value that is output in place of the invalid measured value if the upper limit is violated.

| Data type | Values | Information |
|-----------|------------------------------------|---|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 2,147,483,647 |

Information:

This register must be defined if the replacement value strategy "Replace with static value" was selected in register "[SensorType0x](#)" on page 3749.

9.32.10.8.6.3 Static replacement value when falling below the lower limit

Name:

ReplaceLower01 to ReplaceLower04

This register is used to defined a replacement value that is output in place of the invalid measured value if the lower limit is violated.

| Data type | Values | Information |
|-----------|------------------------------------|--|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: -2,147,483,647 |

Information:

This register must be defined if the replacement value strategy "Replace with static value" was selected in register "[SensorType0x](#)" on page 3749.

9.32.10.8.7 Configuring the user-defined limit values

This module provides the user the option to specify user-defined limits. If the valid measurement range is reduced in this way, the behavior of the replacement value strategy is more likely to be applied.

Valid measurement range

The valid range is derived from the properties of the sensor being used or the hardware and firmware of the respective B&R module. These values cannot be changed by the user.

Valid range of values

The range of values is always within the valid measurement range. The range of values can be adapted to the requirements of the application by specifying the [upper](#) and [lower](#) limit value.

9.32.10.8.7.1 Upper limit value

Name:

UpperLimit01 to UpperLimit04

This register specifies the upper limit value. The values entered should be within the valid measurement range.

| Data type | Values | Information |
|-----------|------------------------------------|---|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 2,147,483,647 |

9.32.10.8.7.2 Lower limit value

Name:

LowerLimit01 to LowerLimit04

This register specifies the lower limit value. The values entered should be within the valid measurement range.

| Data type | Values | Information |
|-----------|------------------------------------|--|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: -2,147,483,647 |

9.32.10.8.7.3 Hysteresis

Name

Hysteresis01 to Hysteresis04

A hysteresis can be set in order to avoid frequent status changes in the measurement range close to the limit value. Here, a small section is defined at the edge of the valid range of values where the measured values retain the status (valid or invalid) of the previous measured value.

| Data type | Values | Information |
|-----------|-------------|------------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 16 |

9.32.10.8.8 Configuring status messages

Errors are detected by the module and sent to the application. When using Function model 0 - Standard, the trigger behavior of these error messages can be influenced by the "Delay" register.

In Automation Studio, an error message can be read either packed as the entire register or individually as bits.

9.32.10.8.8.1 Delaying error messages

Name:

ErrorDelay01 to ErrorDelay04

In order to avoid false alarms due to short-term measurement variations, the status messages transmitted to the PLC can be delayed. This register determines the number of A/D conversions in which an error must exist before an error message is transmitted.

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | AD conversions. Bus controller default setting: 2 |

9.32.10.8.8.2 Delaying the sum error message

Name:

SumErrorDelay01 to SumErrorDelay04

This register can be used to set the delay used when sending bit 5 of the "Status0x" on page 3753 register to the PLC independent of the other status messages.

| Data type | Values | Information |
|-----------|-------------|--------------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 4000 |

9.32.10.8.9 Communication

The received temperature data is stored with a [timestamp](#) and, depending on the configuration, is made available under various register names and data types.

9.32.10.8.9.1 Measured value – Temperature

Name:

Temperature01 to Temperature04

If the channel is configured for resistance measurement, the current temperature value is made available in this register.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

9.32.10.8.9.2 Measured value – Resistance

Name:

Resistor01 to Resistor04

If the channel is configured for resistance measurement, the current resistance value is made available in this register.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.32.10.8.9.3 Measured value – Unweighted

Name:

Measurand01 to Measurand04

When using the AsloAcc library, the unweighted measurement can be accessed via this register. This refers to a measured value that is within the valid measurement range and has not yet been compared with the user-defined limits.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Information:

If no user-defined limits are configured, the value of this register does not differ from the temperature or resistance value.

9.32.10.8.9.4 Cycle counter

Name:

IOCycleCounter01 to IOCycleCounter04

This register is used to provide a continuous counter for the application that is incremented each time a temperature value is read.

| Data type | Value | Information |
|-----------|-------------|----------------|
| USINT | 0 to 32,767 | AD conversion. |
| UINT | 0 to 65,535 | AD conversion. |

9.32.10.8.9.5 Sampling time

Name:

Sampletime01 to Sampletime04

This register provides the application with the NetTime at the time of temperature recording.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Value | Information |
|-----------|---------------------------------|------------------------------|
| INT | -32,768 to 32,767 | NetTime timestamp in μ s |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime timestamp in μ s |

Information:

The SDC library requires a 16-bit value for the sampling time. It is therefore also prepared as a 16-bit value.

9.32.10.8.9.6 Status messages

Name:

Status01 to Status04

The register bits are set if an error has been diagnosed and the error remains longer than the delay configured in the "ErrorDelay0x" on page 3751 register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|--------------------------------------|-------|--|
| 0 | Underrun01 to Underrun04 | 0 | No error |
| | | 1 | Value below the permitted range |
| 1 | Overrun01 to Overrun04 | 0 | No error |
| | | 1 | Value above the permitted range |
| 2 | OpenLine01 to OpenLine04 | 0 | No error |
| | | 1 | Sensor is not connected correctly |
| 3 | Reserved | - | |
| 4 | ConverterFault01 to ConverterFault04 | 0 | No error |
| | | 1 | Invalid A/D converter output |
| 5 | SumFault01 to SumFault04 | 0 | No error |
| | | 1 | Composite error |
| 6 | ParameterFault01 to ParameterFault04 | 0 | No error |
| | | 1 | The "SensorType0x" on page 3749 register is faulty |
| 7 | IoSupplyFault01 to IoSupplyFault04 | 0 | No error |
| | | 1 | The supply voltage (I/O) is faulty |

9.32.10.8.9.7 Status messages for function model 254

Name:

Status01To04

The bits in this register are set if an error has been detected.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|------------------------|-------|---------------------------------|
| 0 | Underrun on channel 01 | 0 | No error |
| | | 1 | Value below the permitted range |
| 1 | Overrun on channel 01 | 0 | No error |
| | | 1 | Value above the permitted range |
| ... | | ... | |
| 6 | Underrun on channel 04 | 0 | No error |
| | | 1 | Value below the permitted range |
| 7 | Overrun on channel 04 | 0 | No error |
| | | 1 | Value above the permitted range |

Information:

If an open line is detected on a channel, then both error messages will be displayed at the same time.

9.32.10.8.10 NetTime Technology

For a description of NetTime Technology, see "NetTime Technology" on page 3035.

9.32.10.8.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.32.10.8.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

| Minimum I/O update time |
|-------------------------|
| 1 ms |

9.32.11 X20ATC402

Data sheet version: 1.31

9.32.11.1 General information

The module is equipped with 6 inputs for J, K, N, S, B, R, E, C and T thermocouple sensors.

This module can also be equipped with the X20TB1E thermocouple terminal block with integrated PT1000 temperature sensors. This makes it possible to achieve optimal terminal temperature compensation.

- 6 channels for thermocouples
- For sensor types J, K, N, S, B, R, E, C, T, raw value measurement
- Integrated terminal temperature compensation
- 2x PT1000 sensor integrated in the terminal (X20TB1E)
- 2x external PT1000 sensor can be connected (X20TB1F)
- Configurable filter time
- NetTime timestamp: Moment of measurement

NetTime timestamp of the measurement

For many applications, not only the measured value is important, but also the exact time of the measurement. The module is equipped with a NetTime timestamp function for this that supplies a timestamp for the recorded position and trigger time with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.32.11.2 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | Temperature measurement |  |
| X20ATC402 | X20 temperature input module, 6 thermocouple inputs, type J, K, N, S, B, R, E, C, T, NetTime function, 2x PT1000 integrated in terminal block X20TB1E for temperature compensation, order terminal block separately. | |

Table 654: X20ATC402 - Technical data

- 1) With a 50 Hz filter, x = 20 ms (1 / 50 Hz = 20 ms)
- 2) Based on the current measured value.
- 3) Based on the entire measurement range.

9.32.11.4 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description | |
|--|--------------|---|--------------------------------|---|------------------|
|  | S | Green | Off | No power to module | |
| | | | Single flash | RESET mode | |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ | |
| | | | Blinking | PREOPERATIONAL mode | |
| | | | On | RUN mode | |
| | | Red | Off | No power to module or everything OK | |
| | | | On | Error or reset status | |
| | | | Single flash | A parameter or conversion error has occurred. This status is output in addition to a single/double flash on the channel LED of the analog input where the error occurs. | |
| | | | Solid red / Single green flash | | Invalid firmware |
| | | | 1 - 6 | Green | Off |
| | Single flash | A parameter error has occurred. A single flash is output on the red "s" module status LED. | | | |
| | Double flash | A conversion error has occurred. A single flash is output on the red "s" module status LED. | | | |
| | Blinking | Overflow, underflow or open line | | | |
| | On | Analog/digital converter running, value OK | | | |

1) Depending on the configuration, a firmware update can take up to several minutes.

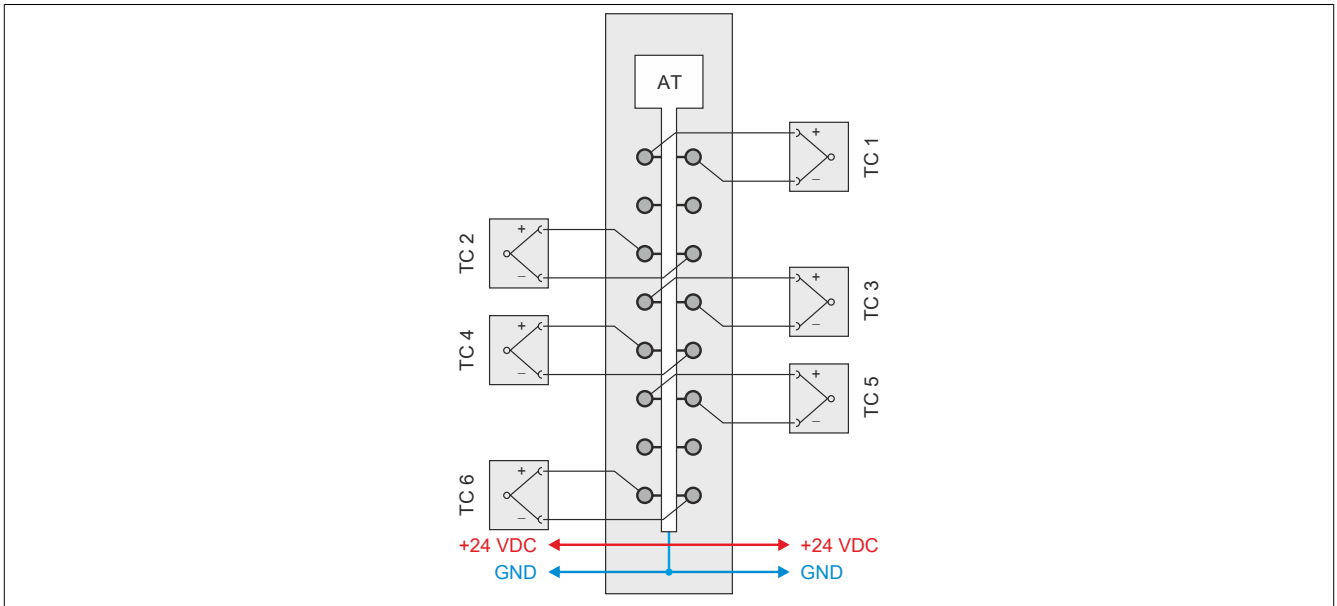

9.32.11.5 Pinout

9.32.11.6 Connection examples

Internal temperature compensation

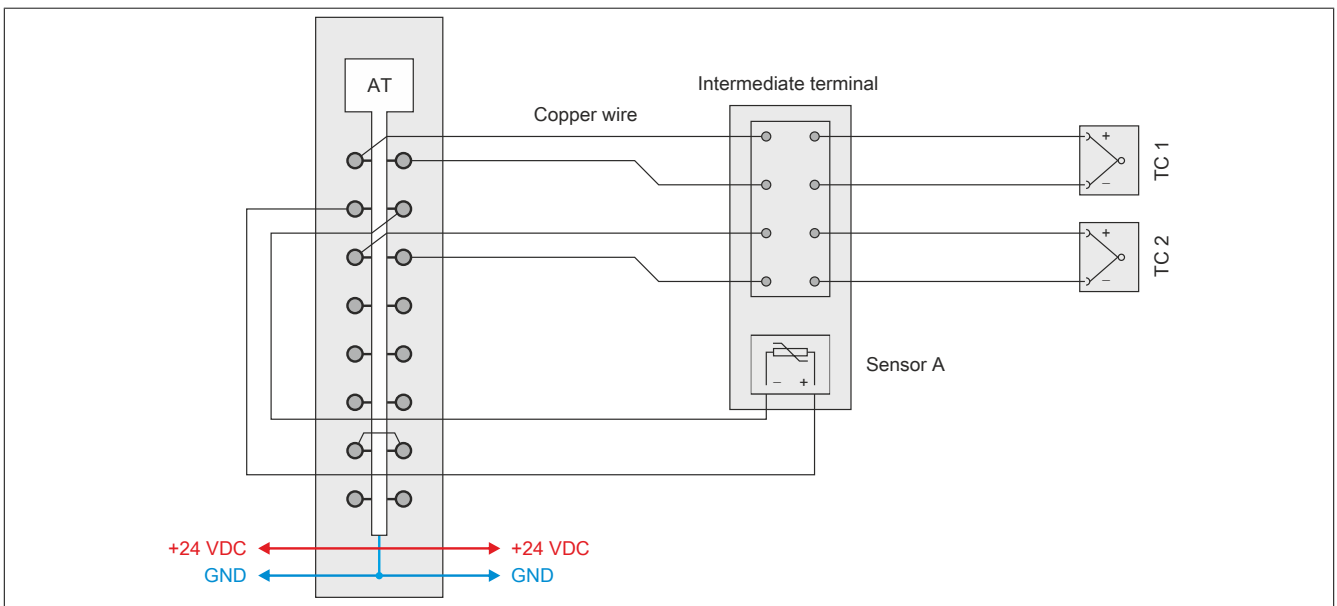

The thermocouple terminal X20TB1E with integrated PT1000 sensors is used for internal temperature compensation.

Remote temperature compensation

The 16-pin X20TB1F standard terminal block is used for remote temperature compensation. The external PT1000 sensors are connected to the module using 2-wire connections.

If Sensor B is not needed for temperature compensation, then the terminal points need to be bypassed.

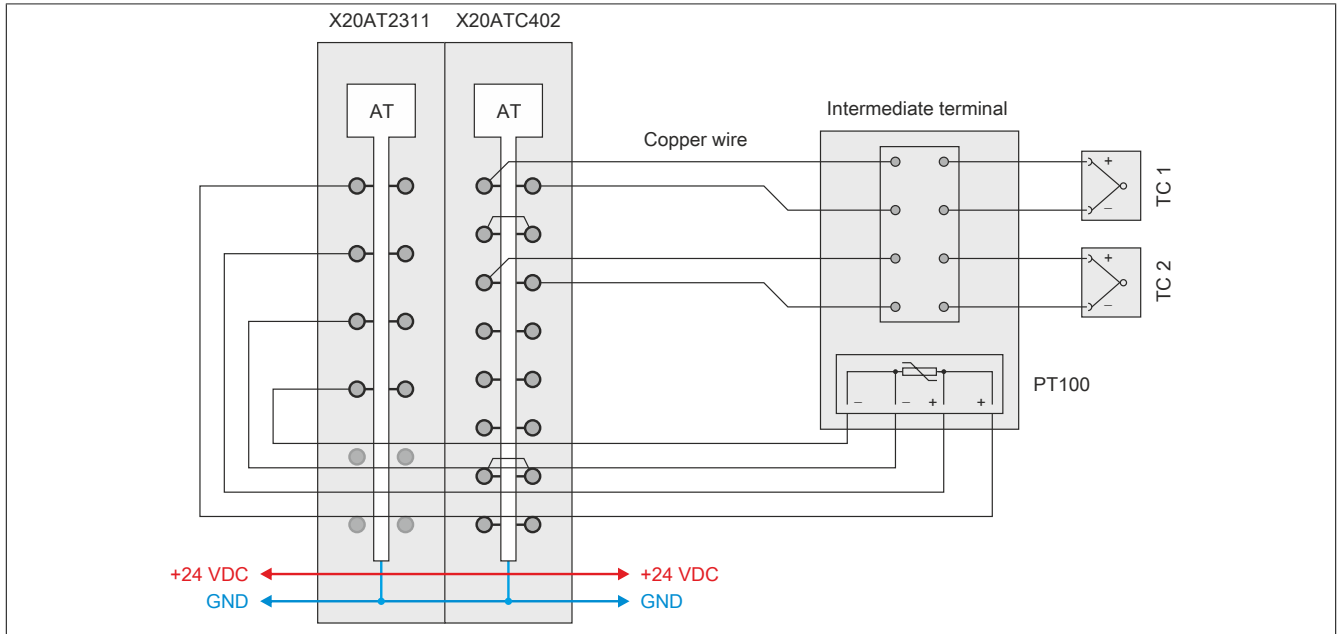

External temperature compensation

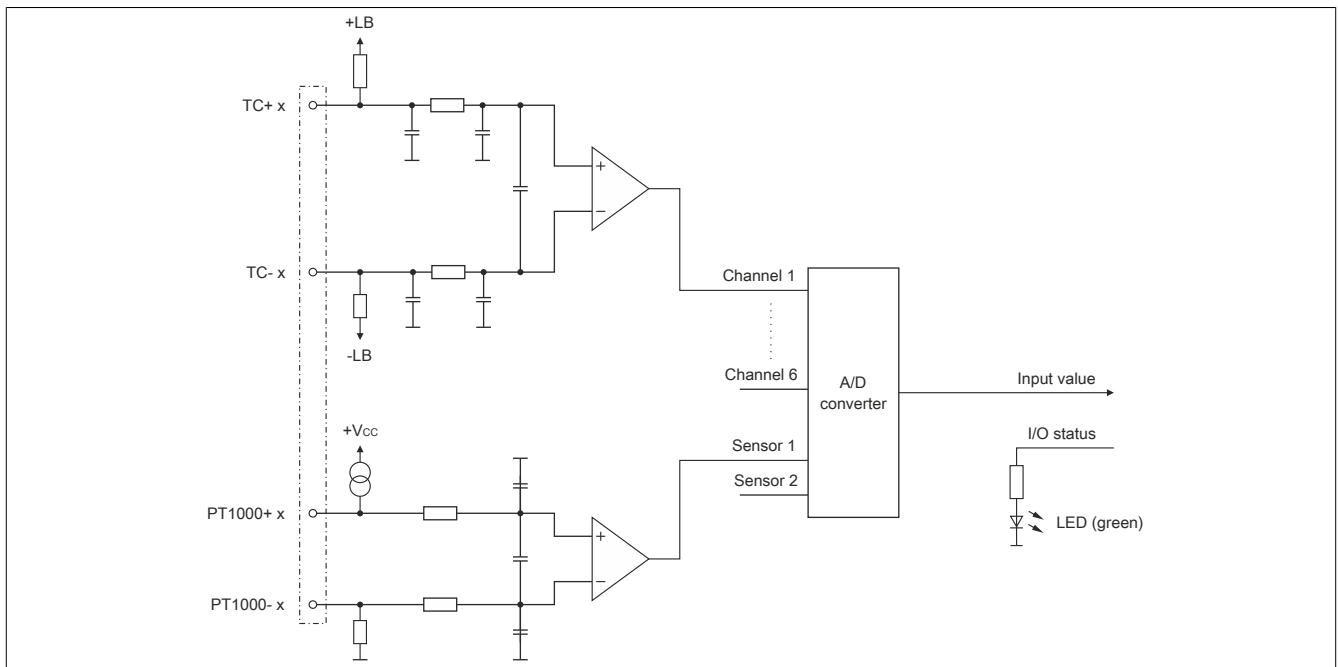

External compensation does not require the PT1000 values to be converted internally in the module. Instead, the reference temperatures have to be pre-processed in the program before being stored in the module. A separate register is available for each temperature channel to transfer an externally pre-processed compensation value.

In the following example, the compensation value is determined using the X20AT2311 temperature input module and a PT100 sensor on the intermediate terminal. The cold junction temperature determined externally is then made available to the X20ATC402 module via the respective I/O data points.

Since sensors A and B aren't needed for temperature compensation, the respective terminal points need to be bypassed.

9.32.11.7 Input circuit diagram

9.32.11.8 Remote or external terminal temperature compensation

Setting up a remote or external cold junction can provide the most accurate temperature measurement in a machine or system.

The installation of a remote or external cold junction is especially helpful in the following cases.

- There is no module next to the temperature module
- With strongly fluctuating environmental conditions (draft, temperature)
- External fan is used in the control cabinet

9.32.11.9 Register description

9.32.11.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.32.11.9.2 Function model 0 - Standard

| N * 64 + 258 | - | Measurand0N (index N = 1 to 6) | INT | | • | | |
| N * 64 + 281 | - | IOCycleCounter0N (index N = 1 to 6) | USINT | | • | | |
| 30 | - | ModuleStatus01 | USINT | | • | | |
| 31 | - | ModuleStatus02 | USINT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.32.11.9.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "Using I/O modules on the bus controller" on page 3789.

9.32.11.9.3.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.32.11.9.4 Module configuration

The module is an I/O module for temperature measurement and requires a 16-pin standard terminal block or the 16-pin terminal block with 2 integrated PT1000 inputs for temperature compensation.

2 measuring resistors (PT1000) can be connected via pin pairs 12/22 and 17/27 to record the absolute compensation temperature. This comparative value is used as a reference for the actual temperature measurement.

9.32.11.9.4.1 Input filter

Name:

Cfo_InputFilter

Mit Hilfe dieses Registers wird die Abtastzeit des A/D-Wandlers konfiguriert. Die eingestellte Filter-/Abtastzeit gilt gleichermaßen für die Eingänge der Thermoelemente als auch des Temperaturwiderstandes.

| Datentyp | Werte | Filterzeit in ms | Wandelrate in s ⁻¹ |
|----------|-------|-----------------------------|-------------------------------|
| UINT | 4 | 1 | 1000 |
| | 9 | 2 | 500 |
| | 48 | 10 | 100 |
| | 80 | 16,7 | 60 |
| | 96 | 20 (Bus Controller Default) | 50 |
| | 160 | 33,3 | 30 |
| | 192 | 40 | 25 |
| | 320 | 66,7 | 15 |
| | 480 | 100 | 10 |
| | 960 | 200 | 5 |

Information:

Je geringer die Wandelrate konfiguriert wird, desto genauer kann der Wert gewandelt werden. Allerdings wird dadurch auch die I/O-Updatezeit erhöht.

9.32.11.9.5 Compensation

The measurement process is based on the interaction between the temperature sensors and the thermocouples. The converted voltage value of a thermocouple has a linear relationship with the difference in temperature between the measurement point and the transition point. To calculate the absolute temperature at the measurement point, the measured value must then be placed in relation to an absolute reference temperature.

The compensation value required for this can be determined as follows:

- Value determined directly on the module using a PT1000 temperature sensor. ("[Internal compensation on page 3765](#)")
- Value provided via a cyclic data point. ("[External compensation on page 3767](#)")

9.32.11.9.5.1 Internal compensation

The inputs of the temperature resistors are used for internal compensation. The module can be used with the 16-pin terminal block (X20TB1E), which has 2 PT1000 temperature sensors.

When operating the module with the X20TB1E, the temperature distribution on the terminal block must be taken into account. To do this, various models for calculating the temperature distribution have been implemented on the module. They account for both the ambient temperature in the control cabinet, as well as the mounting orientation of the module. This helps minimize measurement error.

Alternatively, the module can be operated with the standard 16-pin terminal block (X20TB1F). For a detailed description of this procedure, see "[Remote terminal block on page 3767](#)".

Information:

To avoid unnecessary traffic on the X2X Link network, the compensation registers should only be transferred cyclically during the fine-tuning process and for service and maintenance purposes. The information is generally not required during normal operation.

Setting the compensation parameters

Name:

Cfo_ClampTypeA, Cfo_ClampTypeB

These registers specify the type of sensor and registers the conversion of the compensation value on the A/D converter.

Four different temperature distribution models have been built into the module, optimized for the various ways the module can be installed. The respective model is selected using bits 4 (installation parameter) and 5 (thermal radiance).

| Data type | Value | Information |
|-----------|-------------------|---|
| UINT | See bit structure | Bus controller default setting value: 0 |

Bit structure:

| Bit | Name | Value | Information |
|--------|--|-------|--|
| 0 | Sensor type | 0 | PT1000 (bus controller default setting) |
| | | 1 | Reserved |
| 1 | Compensation channel (on/off) | 0 | Channel not converted by the AD converter (bus controller default setting) |
| | | 1 | Channel registered on the AD converter |
| 2 | Compensation value (see register " Compensation value on page 3766 ") | 0 | Prepare as temperature value (bus controller default setting) |
| | | 1 | Prepare as resistance value |
| 3 | Reserved | - | |
| 4 | Installation parameter | 0 | Horizontal mounting orientation (bus controller default setting) |
| | | 1 | Vertical mounting orientation |
| 5 | Thermal radiance ¹⁾ | 0 | Low (bus controller default setting) |
| | | 1 | High |
| 6 - 15 | Reserved | - | |

1) If an active module that generates additional heat is installed in the immediate vicinity of the temperature module, then this parameter should be set to 1.

Compensation offset

Name:

Cfo_ClampOffsetA, Cfo_ClampOffsetB

These registers define the offsets that are deducted from the respective compensation values.

| Data type | Value | Information |
|-----------|-----------------|--|
| INT | -32767 to 32767 | In 0.1 Ω . Bus controller default setting: 0 |

Compensation value

Name:

CompensationValueA, CompensationValueB

These registers can be used to read the compensation value. Depending on how the "Cfo_ClampType" on page 3765 register is set, it is output as either a temperature or resistance value.

| Data type | Value | Information |
|-----------|-----------------|--------------------------|
| INT | -32767 to 32767 | in 0.1°C or 0.1 Ω |

Status of the compensation value

Name:

CompensationStatusA, CompensationStatusB

UnderrunA, UnderrunB

OverrunA, OverrunB

OpenLineA, OpenLineB

ConverterFaultA, ConverterFaultB

SumFaultA, SumFaultB

ParameterFaultA, ParameterFaultB

These registers provide information about the current status of the respective compensation value. The structure is based on the "Status" on page 3772 register.

| Data type | Value |
|-----------|-------------------|
| USINT | See bit structure |

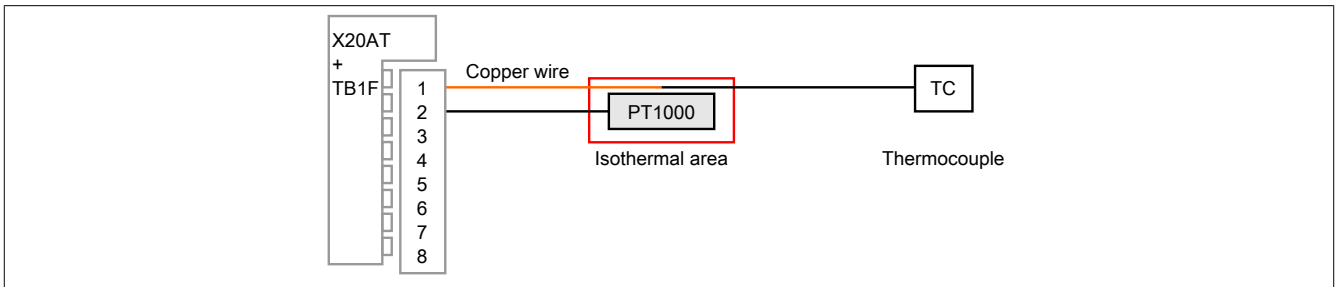

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------------|-------|---|
| 0 | UnderrunA | 0 | No error |
| | UnderrunB | 1 | Value below the permitted range |
| 1 | OverrunA | 0 | No error |
| | OverrunB | 1 | Value above the permitted range |
| 2 | OpenLineA | 0 | No error |
| | OpenLineB | 1 | Open line |
| 3 | (Compensation error) | - | No meaning |
| 4 | ConverterFaultA | 0 | No error |
| | ConverterFaultB | 1 | Converter error |
| 5 | SumFaultA | 0 | No error |
| | SumFaultB | 1 | Undelayed composite error |
| 6 | ParameterFaultA | 0 | No error |
| | ParameterFaultB | 1 | Invalid setting for "ClampType" on page 3765 register |
| 7 | Reserved | - | |

Remote terminal block

The 16-pin standard terminal block (X20TB1F) is used. The reference point for temperature measurements can be moved from the terminal to a more thermally stable location. This can help to minimize measurement error and increase accuracy.

Principle of remote terminal block

The thermocouple provides $V(\Delta T)$ between the end of the thermocouple and the transition to the copper wire.

The PT1000 sensor provides the absolute temperature of the isothermal area.

Calculation: $T(\text{TC}) = T(\text{PT1000}) + \Delta T$

9.32.11.9.5.2 External compensation

For external compensation, the reference temperatures must be prepared in the application and transferred to the module via X2X Link. There is no need for internal conversion of the PT1000 values in the module.

External compensation value

Name:

ExternalCompensation01 to ExternalCompensation06

These registers can be used to send an externally generated compensation value to the module.

| Data type | Value | Information |
|-----------|-----------------|-------------|
| INT | -32767 to 32767 | in 0.1°C |

9.32.11.9.6 Temperature measurement - Configuration

The temperature measurement channels can be configured independently of each other. The "Cfo_SensorType" on page 3768 register needs to be adjusted in order to enable a temperature channel. The rest of the registers complement this configuration and only need to be defined if required in the application.

9.32.11.9.6.1 Configuring temperature measurement

Name:

Cfo_SensorType01 to Cfo_SensorType06

These registers control the basic functionality of a temperature channel.

| Data type | Value | Bus controller default setting |
|-----------|-------------------|--------------------------------|
| UINT | See bit structure | 33792 |

Bit structure:

| Bit | Name | Value | Information |
|-------|--|---------|--|
| 0 - 5 | Sensor type | 0 | Sensor J (Fe-CuNi) (bus controller default setting) |
| | | 1 | Sensor K (NiCr-Ni) |
| | | 2 | Sensor N (NiCrSi-NiSi) |
| | | 3 | Sensor S (PtRh10-Pt) |
| | | 4 | Sensor R (PtRh13-Pt) |
| | | 5 | Sensor C (WRe5-WRe26) |
| | | 6 | Sensor T (Cu-CuNi) |
| | | 7 | Sensor B (PtRh30-PtRh6) |
| | | 8 | Sensor E (NiCr-CuNi) |
| | | 9 to 60 | Reserved |
| 6 - 7 | Reserved | - | |
| | | 61 | Resolution 1.0625 μ V; measurement range \pm 35 mV |
| | | 62 | Resolution 2.125 μ V; measurement range \pm 70 mV |
| 8 - 9 | Reference method | 63 | Reserved |
| | | 0 | PT1000 sensor (bus controller default setting) |
| | | 1 to 2 | Not permitted |
| 10 | Temperature model for X20TB1E ¹⁾ | 3 | External compensation |
| | | 0 | Disabled (bus controller default setting) |
| 11 | Method of compensation | 1 | Enabled |
| | | 0 | Internal compensation (bus controller default setting) |
| 12 | Reserved | 1 | External compensation |
| | | - | |
| 13 | Replacement value strategy | 0 | Replace with static default value (bus controller default setting) |
| | | 1 | Retain last valid value |
| 14 | Additional user-defined limits for permitted range of values | 0 | Permissible range of values of the thermocouple (bus controller default setting) |
| | | 1 | Range of values as configured ²⁾ |
| 15 | Temperature channel | 0 | Channel not converted by the AD converter |
| | | 1 | Channel registered on the AD converter (bus controller default setting) |

1) To enable the temperature model, both PT1000 cold junction sensors must be connected.

2) The user-defined limit values can further reduce the permitted range of values for the sensor, depending on the requirements of the application. It is not permitted to define a measurement range larger than the range supported by the sensor.

9.32.11.9.6.2 Defining the preparation interval

Name:

Cfo_PreparationInterval01 to Cfo_PreparationInterval06

If the last valid measured value should be kept when violating the limit value, then PreparationInterval must be defined. The measured values continue to be acquired and converted according to the configured I/O update time. They are then checked and discarded if they do not meet the specifications. When an error does not occur, therefore, the measured value acquired 2 preparation intervals ago is constantly output.

| Data type | Value | Information |
|-----------|------------|---|
| UINT | 0 to 65535 | In 0.1 ms. Bus controller default setting: 0 |

| | |
|--|--|
| <p>Functionality: Measured values are continuously converted and stored to measured value memory depending on the configured input filter. The current contents of the measured value memory are checked within the configured interval. If a permissible value is present, then the contents of the buffer memory are passed to output memory and the contents of the measured value memory are passed to the buffer. If the check turns up an impermissible value, then the contents of the measured value memory are discarded. The copy direction between the output and buffer memory reverses and the last valid value continues to be output.</p> <p>Information: If configured to keep the last valid value, the delay time from measuring to outputting the value will be at least twice the preparation interval. In the worst case scenario, this can also take twice the interval time plus the configured conversion rate of the A/D converter.</p> | <p>"Application" Value being measured (analog)</p> |
| | <p>↓ Condition: - Conversion interval (A/D converter) elapsed</p> |
| | <p>"Measured value memory" Measured value (digital)</p> |
| | <p>↓ Condition: - PreparationInterval elapsed - Measured value permissible</p> |
| | <p>"Buffer" Last valid value</p> |
| <p>↓ Condition: - PreparationInterval elapsed - Measured value permissible</p> | |
| <p>"Output memory" Next-to-last valid/ displayed value</p> | |

Information:

The registers are only set for the channel when bit 13 is set in the "Cfo_SensorType" on page 3768 register.

9.32.11.9.6.3 Upper replacement value

Name:

Cfo_ReplaceUpper01 to Cfo_ReplaceUpper06

This register is used to define the static values to be displayed instead of the current measured value when the limit is violated.

| Data type | Value | Information |
|-----------|-----------------|---------------------------------------|
| INT | -32767 to 32767 | Bus controller default setting: 32767 |

Information:

The registers are only set for the channel when bit 13 is not set in the "Cfo_SensorType" on page 3768 register.

9.32.11.9.6.4 Lower replacement value

Name:

Cfo_ReplaceLower01 to Cfo_ReplaceLower06

This register is used to define the lower static values to be displayed instead of the current measured value when the limit is violated.

| Data type | Value | Information |
|-----------|-----------------|--|
| INT | -32767 to 32767 | Bus controller default setting: -32767 |

Information:

The registers are only set for the channel when bit 13 is not set in the "Cfo_SensorType" on page 3768 register.

9.32.11.9.6.5 Upper limit value

Name:

Cfo_UpperLimit01 to Cfo_UpperLimit06

If the value range needs to be restricted further, these registers can be used to enter new user-specific upper limit values.

| Data type | Value | Information |
|-----------|-----------------|---------------------------------------|
| INT | -32767 to 32767 | Bus controller default setting: 32767 |

9.32.11.9.6.6 Lower limit value

Name:

Cfo_LowerLimit01 to Cfo_LowerLimit06

If the value range needs to be restricted further, these registers can be used to enter new user-specific lower limit values.

| Data type | Value | Information |
|-----------|-----------------|--|
| INT | -32767 to 32767 | Bus controller default setting: -32767 |

9.32.11.9.6.7 Hysteresis

Name:

Cfo_Hysteresis01 to Cfo_Hysteresis06

If the user-specific limit values are being used, then a hysteresis range should also be defined. These registers configure how far a limit value can be exceeded before a response is triggered.

| Data type | Value | Information |
|-----------|-----------------|------------------------------------|
| INT | -32767 to 32767 | Bus controller default setting: 16 |

9.32.11.9.6.8 Error delay

Name:

Cfo_ErrorDelay01 to Cfo_ErrorDelay06

These registers describe the number of consecutive conversion procedures where an error is pending until the corresponding individual error status bit is set. The delay applies to underflow, overflow and open circuit errors. This delay can be used to hide temporary measured value deviations, for example.

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | AD conversions. Bus controller default setting: 2 |

9.32.11.9.6.9 Error delay for composite error bit

Name:

Cfo_SumErrorDelay01 to Cfo_SumErrorDelay06

These registers can be used to set the time that an error must remain pending before the composite error bit is set.

| Data type | Values | Information |
|-----------|-------------|--------------------------------------|
| UINT | 0 to 65,535 | Bus controller default setting: 4000 |

9.32.11.9.7 Temperature measurement

The received temperature data is prepared in 2 different formats and given a [timestamp](#). For each channel there are 2 separate registers for transmitting the measured values to the PLC.

9.32.11.9.7.1 Temperature measurements

Name:

Temperature01 to Temperature06

Measurand01 to Measurand06

These registers contain the analog input values according to the sensor type set in the "[Cfo_SensorType](#)" on page 3768 register:

| Data type | Value | Information | Sensor type |
|------------------|--|---|-----------------------|
| INT | -2,100 to 12,000 | (for -210.0 to 1200.0 °C) | Type J (Fe-CuNi) |
| | -2,700 to 13,720 | (for -270.0 to 1372.0 °C) | Type K (NiCr-Ni) |
| | -2,700 to 12,980 | (for -270.0 to 1298.0 °C) | Type N (NiCrSi-NiSi) |
| | -500 to 17,680 | (for -50.0 to 1768.0 °C) | Type S (PtRh10-Pt) |
| | -500 to 17,600 | (for -50.0 to 1760.0 °C) | Type R (PtRh13-Pt) |
| | 0 to 23,100 | (for 0 to 2310.0 °C) | Type C (WRe5-WRe26) |
| | -2,700 to 4,000 | (for -270.0 to 400.0 °C) | Type T (Cu-CuNi) |
| | 0 to 18,200 | (for 0 to 1820.0 °C) | Type B (PtRh30-PtRh6) |
| | -2,700 to 9,970 | (for -270.0 to 997.0 °C) | Type E (NiCr-CuNi) |
| | -32,768 to 32767 | Voltage without linearization and terminal temperature compensation Resolution 1.0625 µV for a measurement range of ±35 mV | |
| -32,768 to 32767 | Voltage without linearization and terminal temperature compensation Resolution 2.125 µV for a measurement range of ±70 mV | | |

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is switched off, 0x8000 is output.
- If an I/O voltage supply failure occurs, 0x8000 is output.

9.32.11.9.7.2 Sample time

Name:

SampleTime01 to SampleTime06

These registers return the timestamp for when the module reads the current channel mapping. The values are provided as signed 2-byte or 4-byte values.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values | Information |
|-----------|---------------------------|--|
| INT | -32,768 to 32767 | NetTime timestamp of the current input value in µs |
| DINT | -2147483648 to 2147483647 | NetTime timestamp of the current input value in µs |

9.32.11.9.7.3 I/O cycle counter

Name:

IOCycleCounter01 to IOCycleCounter06

These registers are cyclic counters that are incremented each time a value is converted. They can be used as either 1-byte or 2-byte counters.

| Data type | Value |
|-----------|------------|
| USINT | 0 to 255 |
| UINT | 0 to 65535 |

9.32.11.9.7.4 Status messages (Function model 0)

Name:

Status01 to Status06

Underrun01 to Underrun06

Overrun01 to Overrun06

OpenLine01 to OpenLine06

CompensationFault01 to CompensationFault06

ConverterFault01 to ConverterFault06

SumFault01 to SumFault06

ParameterFault01 to ParameterFault06

The current error status of the module channels is displayed in these registers, regardless of the configured replacement value strategy. Some error information may be delayed according to the conditions configured previously in the "[Cfo_ErrorDelay](#)" on page 3770 and "[Cfo_SumErrorDelay](#)" on page 3770 registers.

| Data type | Value |
|-----------|--------------------|
| USINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|---------------------|-------|---|
| 0 | Underrun0x | 0 | No error |
| | | 1 | Value below the permitted range |
| 1 | Overrun0x | 0 | No error |
| | | 1 | Value above the permitted range |
| 2 | OpenLine0x | 0 | No error |
| | | 1 | Open line |
| 3 | CompensationFault0x | 0 | No error |
| | | 1 | Compensation error; See " CompensationStatus " on page 3766 register for a detailed error description |
| 4 | ConverterFault0x | 0 | No error |
| | | 1 | Converter error |
| 5 | SumFault0x | 0 | No error |
| | | 1 | Undelayed composite error |
| 6 | ParameterFault0x | 0 | No error |
| | | 1 | Invalid configuration for " Cfo_ClampType " on page 3765 |
| 7 | Reserved | - | |

9.32.11.9.7.5 Status messages (Function model 254)

Name:

ModuleStatus01 to ModuleStatus06

In function model 254, error detection does not have to be preconfigured. It is enabled at every startup. To streamline the transfer, however, only the 4 basic error messages were implemented.

The bits of these registers are set when one of the implemented error diagnostics is triggered.

| Data type | Value |
|-----------|--|
| USINT | Channels 1 to 4: see bit structure I |
| | Channels 5 and 6: see bit structure II |

Bit structure I:

| Bit | Name | Value | Information |
|-------|-----------|----------|--|
| 0 - 1 | Channel 1 | 00 | No error |
| | | 01 | Underflow (lower value limit violated) |
| | | 10 | Overflow (upper value limit violated) |
| | | 11 | Open line |
| 2 - 3 | Channel 2 | 00 to 11 | See channel 1 |
| 4 - 5 | Channel 3 | 00 to 11 | See channel 1 |
| 6 - 7 | Channel 4 | 00 to 11 | See channel 1 |

Bit structure II:

| Bit | Name | Value | Information |
|-------|-----------|----------|--|
| 0 - 1 | Channel 5 | 00 | No error |
| | | 01 | Underflow (lower value limit violated) |
| | | 10 | Overflow (upper value limit violated) |
| | | 11 | Open line |
| 2 - 3 | Channel 6 | 00 to 11 | See channel 5 |
| 4 - 7 | Reserved | - | |

9.32.11.9.8 NetTime Technology

For a description of NetTime Technology, see ["NetTime Technology" on page 3035](#).

9.32.11.9.9 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 µs |

9.32.11.9.10 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

The A/D converter must convert multiple values. After switching between 2 inputs there are 4 measurements in order to obtain a meaningful value. Since not all inputs need to be used, the actual I/O update time may vary.

The following formulas can be used to calculate the minimum required I/O update time:

$$\text{I/O update time} = 4 * \text{Conversions} * \text{Filter time}$$

$$\text{Filter time} = (1024 / 4920000) * C_{fo_InputFilter}$$

$$\text{Conversions} = \text{Number of thermocouples} + \text{Number of temperature resistors}$$

9.33 Terminal blocks

Various terminal blocks are available for wiring X20 modules.

9.33.1 Summary

| Model number | Short description | Page |
|--------------|--|------|
| X20TB06 | X20 terminal block, 6-pin, 24 VDC keyed | 3775 |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | 3775 |
| X20TB1E | X20 terminal block, 12-pin, 24 VDC keyed, 2x PT1000 integrated for terminal temperature compensation | 3778 |
| X20TB1F | X20 terminal block, 16-pin, 24 VDC keyed | 3781 |
| X20TB32 | X20 terminal block, 12-pin, 240 VAC keyed | 3784 |

9.33.2 X20TB06/X20TB12

Data sheet version: 2.65

9.33.2.1 General information

The X20 24 VDC modules are wired using the X20TB06 and X20TB12 terminal blocks.

- Tool-free wiring with push-in technology
- Simple wire release using lever
- Ability to label each terminal
- Plain text labeling also possible
- Test access for standard probes
- Can be customer-coded

9.33.2.2 Order data

Table 656: X20TB06, X20TB12 - Technical data

- 1) Take the respective limit data for the I/O modules into consideration!
2) Identical for operation, storage and transport.

Warning!

It is possible to come into contact with parts that carry voltage when the terminal block is disconnected. For this reason, working on a disconnected terminal block is not permitted at voltages starting at 50 V.

9.33.2.4 Unique terminal numbering

Each terminal connection is unique and can be identified by the numbers in the plastic. In this way, terminal assignments can be clearly assigned in the planning stage without any danger of mix-up.

- Upper number: Row number 1 or 2
- Lower number: Terminal numbers 1 to 3 (6-pin terminal block), 1 to 6 (12-pin terminal block), 1 to 8 (16-pin terminal block)

9.33.2.5 Wiring

In order to achieve a secure connection in the terminal blocks, wires must be stripped accordingly.

Figure 367: Wire stripping length for a secure connection

Information:

The wire stripping length is not permitted to be more or less than 7 to 9 mm.

9.33.2.6 Cable holding force of contacts

To ensure secure contact of a cable with the terminal block, it is not permitted to be subjected to too much tension. If the cable holding force is exceeded, the cable will disconnect from the terminal block and result in a malfunction.

| Cable in mm ² | Fine-stranded wires | | | Solid wires | | | | With wire end sleeves | |
|--|---------------------|-----|-----|-------------|------|-----|-----|-----------------------|-----|
| | 0.25 | 1.5 | 2.5 | 0.08 | 0.25 | 1.5 | 2.5 | 0.25 | 1.5 |
| Standard specification (min. value in newtons) | 12.5 | 40 | 50 | 4 | 12.5 | 40 | 50 | 12.5 | 40 |

Information:

Fine-stranded wires must be twisted in order to maintain the cable holding forces.

Use of wire end sleeves

In order to achieve an optimal cable holding force, the following points must be observed:

- Square crimping with the roughest possible surface should be carried out.
- The end of the wire end sleeve should not be cut in order to avoid a reduction of the cross section.
- No wires should protrude at the end of the sleeve.
- The wire end sleeve must be inserted completely to the end.
- The length of the wire end sleeve corresponds to the [wire stripping length](#).

9.33.2.7 Access for test probes

Each contact is equipped with an additional opening for using a test probe.

9.33.3 X20TB1E

Data sheet version: 1.55

9.33.3.1 General information

The X20TB1E terminal block is equipped with two integrated PT1000 sensors. It is therefore optimally suited for internal terminal temperature compensation.

- Integrated terminal temperature compensation
- Tool-free wiring with push-in technology
- Simple wire release using a screwdriver
- Ability to label each terminal
- Plain text labeling also possible
- Test access for standard probes
- Can be customer-coded

Use of wire end sleeves

In order to achieve an optimal cable holding force, the following points must be observed:

- Square crimping with the roughest possible surface should be carried out.
- The end of the wire end sleeve should not be cut in order to avoid a reduction of the cross section.
- No wires should protrude at the end of the sleeve.
- The wire end sleeve must be inserted completely to the end.
- The length of the wire end sleeve corresponds to the [wire stripping length](#).

9.33.5.7 Access for test probes

Each contact is equipped with an additional opening for using a test probe.

10 Additional information

10.1 Diagnostic LEDs

LEDs for diagnostics are located at the top of most X20 I/O modules. The following LEDs are available depending on the module to indicate the operating state:

- LEDs "r" (green) and "e" (red)
- LED "s" (red/green) LED

Additional LEDs are module-specific and usually indicate the state of I/O channels. Green LEDs are usually used for inputs, while orange LEDs are usually used for outputs. These I/O LED status indicators are only operational in mode RUN on some modules.

Operating states and error states

The following table provides a complete description of all operating states and error states for X20 I/O modules. The operating state and error state actually indicated by the I/O module depends on the type of module as well as how it is being used.

| | LED | Description | Note | |
|--|---|--|--|--|
|  | All LEDs off | No power to module | The module does not have power. | |
| | Module status: Green LED | | | |
| | Single flash (red LED = Off) | Mode RESET | No connection to the X2X Link master, or the X2X Link master is not yet running. Some modules remain in single flash mode during a firmware update. | |
| | | Not configured | The module was connected behind bus receiver X20BR7300, but it is not configured. ²⁾ | |
| | Single flash (red LED = On) | Invalid firmware | Invalid firmware: Occurs when a firmware update has been interrupted. The firmware is reloaded as soon as the X2X Link master is active again. It is only loaded if the module is also entered in the configuration, however. | |
| | Double flash | BOOT mode (mode RESET with communication) | Firmware update. A firmware update usually only takes place once after the module has been replaced or if new firmware has been loaded to the master CPU during a project update. Depending on the configuration, a firmware update can take several minutes. | |
| | | Not configured | The module was connected behind bus receiver X20BR7300, but it is not configured. ²⁾ | |
| | Blinking | Mode PREOPERATIONAL | Modules whose slot is configured for a different module (or none at all) remain in mode PREOPERATIONAL. Possible errors: <ul style="list-style-type: none"> • Incorrect module connected or slot not configured • Incorrect slot number for bus modules with node number switches | |
| | Blinking quickly | Mode SYNC | Module synchronizing with X2X Link network | |
| | On | Mode RUN | No error | |
| | Error status: Red LED (green LED = On) | | | |
| | Off | | Everything OK | |
| | On | Fatal error | It is not possible for the module to continue functioning correctly. Possible errors: <ul style="list-style-type: none"> • Power supply outside warning range • Operating temperature outside permissible range Monitoring for fatal errors is not integrated into all modules. | |
| | Single flash or blinking | I/O channel error | An error or warning is present on one or more I/O channels. Which channel error on the module is being indicated depends on the module and can be determined with the respective module description. | |
| | Double flash | System errors | A system error occurred in the module. The cause of error depends on the module and can be determined with the respective module description. | |
| | Triple flash | I/O error and system error | An I/O error and system error occurred at the same time. | |
| | Single flash, inverted ¹⁾ | Fatal error and I/O error | A fatal error and I/O error occurred at the same time. | |
| | Double flash, inverted ¹⁾ | Fatal error and system error | A fatal error and system error occurred at the same time. | |
| Triple flash, inverted ¹⁾ | Fatal error, I/O error and system error | A fatal error, I/O error and system error occurred at the same time. | | |

1) Only on modules that monitor for fatal errors.

2) The blinking behavior (single or double flash) depends on the X20 module being used.

LED status indicators - Blinking patterns

The blinking patterns shown in this image specify only the principle ratio between the switch-on and switch-off time for the LED. The actual ratio of blink times to each other can vary depending on the module.

10.2 Using I/O modules on the bus controller

If an I/O module is used after a bus controller, the X2X module registers and functions that can be used depend on the bus controller used.

- **Non-configurable bus controllers**

By default, "Function model 254 - Bus controller" is used here. This includes:

- **CAN I/O bus controllers:** X20BC0073, X67BC7321, X67BC7321-1
- **DeviceNet bus controllers:** X20BC0053, X67BC5321

- **PROFIBUS bus controllers**

Only the X2X module registers listed in the PROFIBUS user's manual can be used for the supported modules. The PROFIBUS user's manual can be downloaded from the B&R website.

- **PROFINET bus controllers**

Only the X2X module registers listed in the GSDML file can be used for the supported modules. This file can be downloaded from the B&R website. The PDF document included in the GSDML package lists all available X2X module registers.

- **Using the automatic configuration**

With all other bus controllers, "Function model 254 - Bus controller" is used by default when using the automatic configuration.

- **Fully configurable bus controllers**

When operating an I/O module on a fully configurable bus controller (e.g. X20BC0043-10), all available functions and registers of the respective I/O module can be used. In this case, "Function model 0 - Standard" is used as the default setting when adding X2X modules in Automation Studio.

If additional function models are available in the I/O module (e.g. "Function model OSP" for digital output modules), they can also be used as long as it makes sense to use them with the bus controller. Full configurations for CANopen, Modbus, EtherCAT, EtherNet/IP and POWERLINK can be made with Automation Studio V4.3 or later.

Information:

Automation Studio can be downloaded at no cost from the B&R website (www.br-automation.com). The evaluation license is permitted to be used to create complete configurations for fieldbus bus controllers at no cost.

Overview of possible configuration types

| | CANopen | EtherNet/IP | PROFIBUS | OPC UA | EtherCAT |
|-------------------------|--|-------------------------------|--|---------------------------------------|----------------------------|
| | X20BC0043-10 X20BC0143-10 X67BC4321-10 X67BC4321.L08-10 X67BC4321.L12-10 | X20(c)BC0088 X67BCD321.L12 | X20BC0063 X67BC6321 X67BC6321.L08 X67BC6321.L12 | X20BC008U | X20BC00G3 X67BCG321.L12 |

10.3 General data points

In addition to the registers listed in the register description, X20 modules also have other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

10.3.1 FirmwareVersion

Name:

FirmwareVersion

The firmware version of the module can be read using this data point.

The last two positions correspond to the number after the decimal point.

Example: 345 corresponds to 3.45.

| Data type | Values | Information |
|-----------|----------------|---|
| UINT | 1 to 99 | Release version of older modules or developmental versions of new modules |
| | 100 to 29999 | Release version |
| | 30000 to 59999 | Test version |

10.3.2 HardwareVariant

Name:

HardwareVariant

The hardware variant of the module can be read using this data point.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

10.3.3 ModuleID

Name:

ModuleID

The module ID of the module can be read using this data point. For the module hardware ID, see the respective module documentation. In addition, a serial number is printed on each electronics module; the module hardware ID corresponds to the first four positions of the serial number. (See figure: Hardware ID is also colored black.)

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Information:

IDs starting with 9999 are printed as hexadecimal numbers and must be converted to their decimal values for comparison!

10.3.4 SerialNumber

Name:
SerialNumber

The module's unique serial number can be read using this data point.

The complete serial number is made up of **ModuleID** and **SerialNumber** as follows: Serial number = (Hardware ID * 1E+7) + SerialNumber

The serial number is printed in decimal form on the module's housing.

Example

Hardware ID = (decimal) 1213

Serial number = (decimal) 671339

Serial number = 1213 * 10000000 + 671339 = 12130671339

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

10.3.5 ModuleOK

Name:
ModuleOK

Whether the module is physically present in the slot or not can be read from this register.

| Data type | Value | Information |
|-----------|-------|---------------------------------|
| BOOL | 0 | Module not ready for operation |
| | 1 | Module connected and configured |

10.3.6 StaleData

Name:
StaleData

Whether the transferred data originates from the current cycle or a previous cycle can be read using this data point.

This error can result from cycle times that are too short or disturbances in module communication, for example.

Information:

This data point is only valid if **ModuleOK = 1**.

| Data type | Value | Information |
|-----------|-------|--|
| BOOL | 0 | Data originates from the current cycle |
| | 1 | Data does not originate from the current cycle |

10.4 General CPU data points

Although X20 CPUs do not normally have a register description, they do have several general data points. These are not CPU-specific; instead, they contain general information such as system time and heat sink temperature.

Information:

Some data points and data types are CPU-specific. Not every X20 CPU provides all data points.

10.4.1 BatteryStatusCPU

Name:

BatteryStatusCPU

The state of the battery contained in the CPU can be read from this data point.

| Data type | Values | Information |
|-----------|--------|--|
| USINT | 0 | Battery voltage too low or battery missing |
| | 1 | Battery OK |

10.4.2 ModeSwitch

Name:

ModeSwitch

The operating mode of the CPU can be read from this data point.

| Data type | Values | Information |
|-----------|---------|-------------------------|
| USINT | 0 | Mode BOOT ¹⁾ |
| | 1 to 2 | Reserved ²⁾ |
| | 4 | Mode RUN |
| | 3 to 14 | Reserved ²⁾ |
| | 15 | Mode DIAG ¹⁾ |

1) Value cannot be read since data points can only be evaluated in mode RUN.

2) Currently also used for mode RUN.

10.4.3 StatusInput01

Name:

StatusInput01

The state of the supply voltage can be read from this data point.

| Data type | Values | Information |
|-----------|--------|------------------------------------|
| BOOL | 0 | Supply voltage OK |
| | 1 | Supply voltage outside valid range |

10.4.4 SystemTime

Name:

SystemTime

The starting time of a specific task class in μ s can be read from this data point. The system time is latched at the beginning of the cycle of the task class that contains this data point.

Information:

Because the DINT counter overflows and resets approximately every 70 minutes, it is only possible to read out the relative system time.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

10.4.5 TemperatureCPU

Name:

TemperatureCPU

The internal temperature of the CPU can be read from this data point. The data type depends on the CPU family:

- UINT: Older CPU families (e.g. X20CPx48x), temperature range starts at 0°C
- INT: Newer CPU families (e.g. X20CPx58X, Compact-S CPUs), temperature range starts at -20°C.

| Data type | Values | Information |
|-----------|-----------------|-----------------------|
| UINT | 0 to 65535 | Temperature in 1/10°C |
| INT | -32768 to 32767 | |

10.4.6 TemperatureENV

Name:

TemperatureENV

The temperature of the CPU heat sink can be read from this data point. The data type depends on the CPU family:

- UINT: Older CPU families (e.g. X20CPx48x), temperature range starts at 0°C
- INT: Newer CPU families (e.g. X20CPx58X, Compact-S CPUs), temperature range starts at -20°C.

| Data type | Values | Information |
|-----------|-----------------|-----------------------|
| UINT | 0 to 65535 | Temperature in 1/10°C |
| INT | -32768 to 32767 | |

10.4.7 SupplyVoltage

Name:

SupplyVoltage

This register indicates the bus supply voltage measured at a resolution of 0.1 V.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Voltage in 1/10 V |

10.4.8 SupplyCurrent

Name:

SupplyCurrent

This register displays the bus power supply current measured at a resolution of 0.1 A.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Current in 1/10 A |

10.5 Blackout mode

Blackout mode allows users to continue execution of the application in lower-level subsystems if components of the B&R system fail. In this way, the B&R system – independently of redundancy technology – makes it possible to respond to system-critical situations based on the specific application.

The use of blackout-capable modules is recommended for the following requirements:

- Exit routines on system failure, e.g. to enable the opening of a press if the system fails.
- Stopping or controlled setting of an output on system failure, e.g. to automatically close inflow valves.
- Deceleration sequences on system failure, e.g. to reduce motor speeds before transmitting a stop command.

If blackout-capable modules are configured accordingly, blackout mode will be carried out if the network connection to the higher-level controller or CPU is interrupted.

As soon as the network disturbance has been corrected, blackout mode is stopped by the modules and bumpless synchronization with the network takes place.

Requirements for operation

The following requirements must be met in order to use blackout mode:

- The module being used must support blackout mode.
- Parameter "Blackout mode" must be enabled in Automation Studio.

10.5.1 Areas of use

Through the use of blackout-capable modules, a part of the control system can also remain functional if a disturbance in the network or X2X Link connection between the modules occurs.

10.5.1.1 Loss of POWERLINK connection

Initial situation

Several stations in an application are connected to the CPU via network cables. A fault occurs that interrupts data transfer between the CPU and stations.

Effect

Non-blackout modules are reset and operated according to their default characteristics.

Blackout-capable modules show the following behavior:

- The programmed function continues to be executed.
- Subordinate networks continue to work.
- Data from the CPU is initialized with "0".
- After the disturbance has been corrected, the module bumplessly returns to the higher-level network.

Warning!

Blackout mode causes data from the CPU to be initialized with "0". If blackout mode is used in combination with "output inversion", this can lead to the unwanted setting of outputs.

10.5.1.2 Loss of X2X Link connection

Initial situation

Modules in an application are connected to the network via X2X Link cables. A defect in the X2X Link cable causes the data transfer between the CPU and modules to be interrupted.

Effect

Non-blackout modules are reset and operated according to their default characteristics.

Blackout-capable modules show the following behavior:

- The programmed function continues to be executed.
- Subordinate networks continue to work.
- Data from the CPU is initialized with "0".
- After the disturbance has been corrected, the module bumplessly returns to the higher-level network.

Warning!

Blackout mode causes data from the CPU to be initialized with "0". If blackout mode is used in combination with "output inversion", this can lead to the unwanted setting of outputs.

10.5.2 Programming blackout mode

Blackout mode cannot be detected by the blackout-capable modules themselves. If it is necessary to program specific blackout behavior in an application, an indirect method must therefore be chosen.

One possibility is to implement a counter in the blackout-capable module's higher-level CPU and query it cyclically. Blackout mode would make itself noticeable in this case by a counter value that no longer changes or a counter value of zero.

Blackout-capable modules can be divided into 2 categories:

- **Programmable modules**
The blackout function is programmed using existing function blocks. In other words, the existing technologies for application programming or reACTION Technology are used.
The blackout function is executed largely independently of other system components.
- **Standard function modules**
These modules are not programmable and maintain their default behavior in blackout mode.

10.5.3 Standalone function

The standalone function is an extension of blackout mode. After switching on the power supply, blackout mode is enabled immediately regardless of whether a network connection exists. This means that after switching on the power supply, the module begins executing the most recently saved configuration or application without waiting for activity or synchronization with a higher-level CPU or SafeLOGIC controller.

As soon as the network is active, bumpless synchronization between the module and existing network takes place.

Warning!

Standalone modules act identically to blackout mode on system startup and until the network connection is established. Their use therefore requires extreme caution!

Requirements for operation

The following requirements must be met in order to use the standalone function:

- The module being used must support the standalone function.
- Parameter "Standalone mode" must be enabled in Automation Studio.
- For the standalone function on the bus controller (e.g. X20SL8101), blackout mode is enabled for at least 1 module on the local X2X Link network.
- The module must have been operated with a CPU at least once in order to have a valid configuration.

Information:

The use of the standalone function in connection with DNA is not permitted. Static addresses must be used.

Warning!

The following aspects need to be taken into account in particular:

- **The module must be clearly (and permanently) identified to highlight its distinctive behavior from the standard.**
- **Service technicians must be well-versed with the special characteristics of these modules.**
- **Before connecting the terminal block to a module with an enabled standalone function, at least one of the following conditions must be met:**
 - **It must be ensured that the module is really meant to be operated with the standalone function and the configuration on the module has been checked for correctness.**
 - **The flashing sequence of the module indicates the "normal, network-connected operational state" of the module.**

10.5.3.1 Area of application

Initial situation

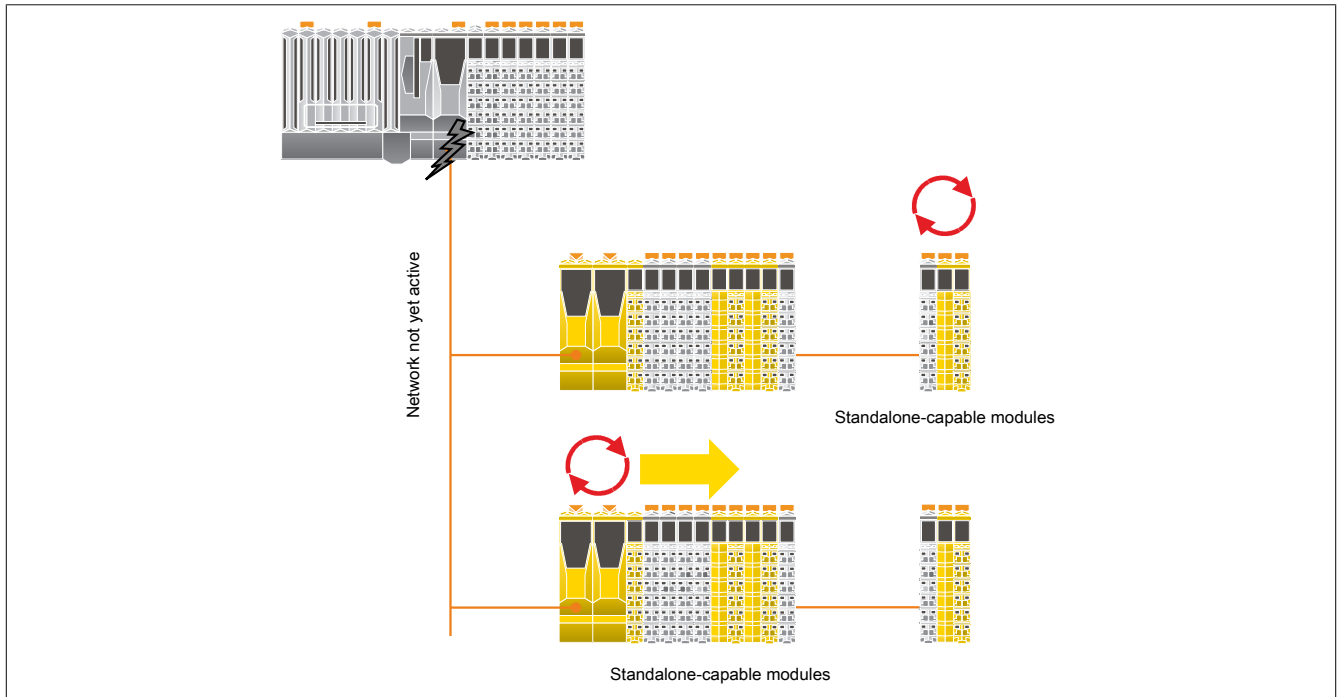

Several stations in an application are connected to the CPU via network cables. After the entire system has been switched off and on, a fault results in the network connection not being established.

Effect

Non-standalone modules are put into the active state only after the application starts up.

Standalone-capable modules show the following behavior:

- The boot procedure is started without waiting on a higher-level network.
- The module behaves identically to blackout mode.
- As soon as the network becomes active, it is bumplessly added to the higher-level network.

10.6 NetTime Technology

NetTime refers to the ability to precisely synchronize and transfer system times between individual components of the controller or network (CPU, I/O modules, X2X Link, POWERLINK, etc.).

This allows the moment that events occur to be determined system-wide with microsecond precision. Upcoming events can also be executed precisely at a specified moment.

10.6.1 Time information

Various time information is available in the controller or on the network:

- System time (on the PLC, Automation PC, etc.)
- X2X Link time (for each X2X Link network)
- POWERLINK time (for each POWERLINK network)
- Time data points of I/O modules

The NetTime is based on 32-bit counters, which are increased with microsecond resolution. The sign of the time information changes after 35 min, 47 s, 483 ms and 648 μ s; an overflow occurs after 71 min, 34 s, 967 ms and 296 μ s.

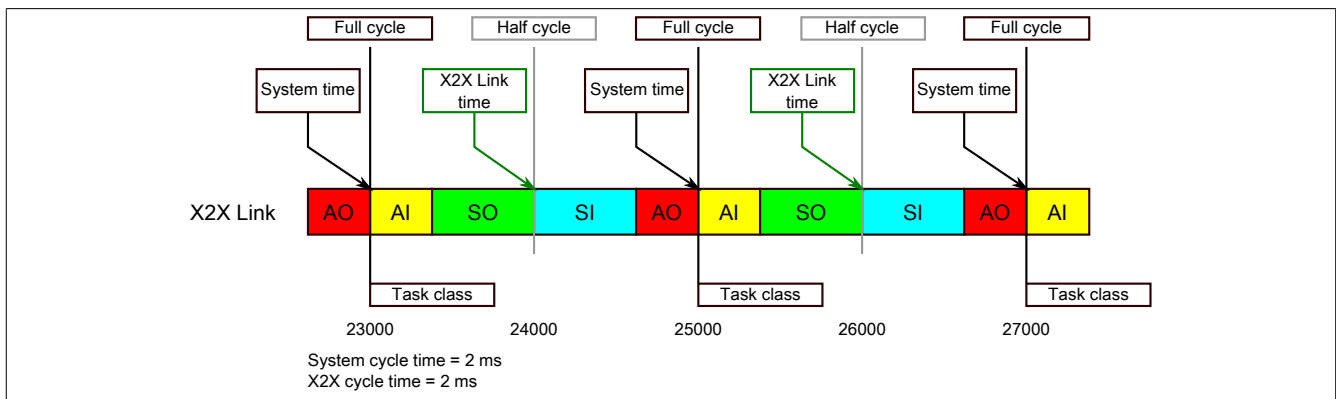

The initialization of the times is based on the system time during the startup of the X2X Link, the I/O modules or the POWERLINK interface.

Current time information in the application can also be determined via library AsIOTime.

10.6.1.1 PLC/Controller data points

The NetTime I/O data points of the PLC or the controller are latched to each system clock and made available.

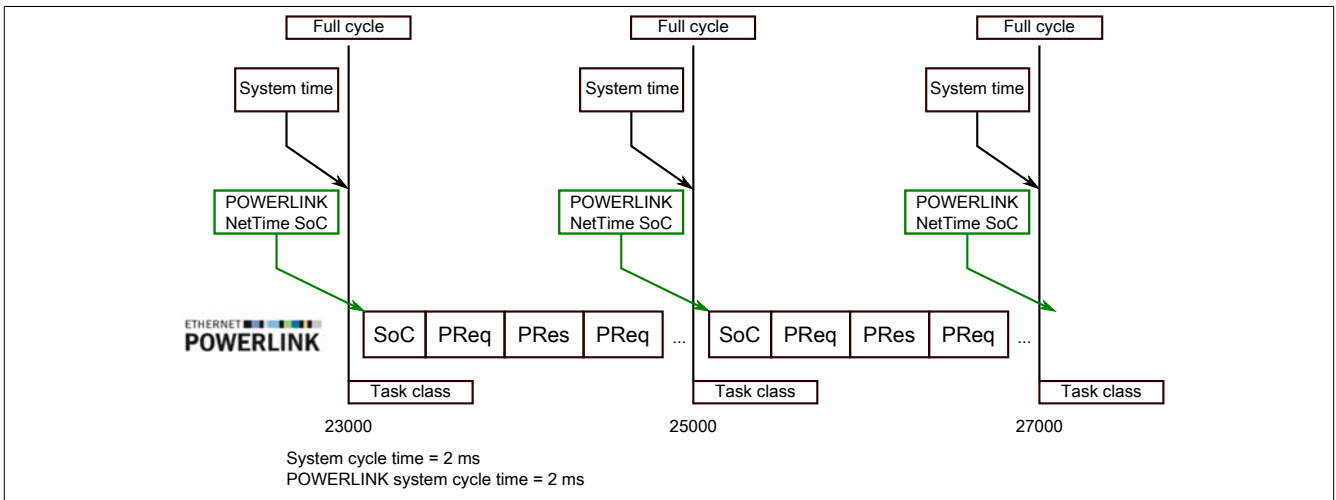

10.6.1.2 X2X Link reference moment

The reference moment on the X2X Link network is always calculated at the half cycle of the X2X Link cycle. This results in a difference between the system time and the X2X Link reference moment when the reference time is read out.

In the example above, this results in a difference of 1 ms, i.e. if the system time and X2X Link reference moment are compared at time 25000 in the task, then the system time returns the value 25000 and the X2X Link reference moment returns the value 24000.

10.6.1.3 POWERLINK reference moment

The reference moment on the POWERLINK network is always calculated at the start of cycle (SoC) of the POWERLINK network. The SoC starts 20 µs after the system tick. This results in the following difference between the system time and the POWERLINK reference time:

$$\text{POWERLINK reference time} = \text{System time} - \text{POWERLINK cycle time} + 20 \mu\text{s}.$$

In the example above, this means a difference of 1980 µs, i.e. if the system time and POWERLINK reference moment are compared at time 25000 in the task, then the system time returns the value 25000 and the POWERLINK reference moment returns the value 23020.

10.6.1.4 Synchronization of system time/POWERLINK time and I/O module

At startup, the internal counters for the PLC/POWERLINK (1) and the I/O module (2) start at different times and increase the values with microsecond resolution.

At the beginning of each X2X Link cycle, the PLC or the POWERLINK network sends time information to the I/O module. The I/O module compares this time information with the module's internal time and forms a difference (green line) between the two times and stores it.

When a NetTime event (E) occurs, the internal module time is read out and corrected with the stored difference value (brown line). This means that the exact system moment (S) of an event can always be determined, even if the counters are not absolutely synchronous.

Note

The deviation from the clock signal is strongly exaggerated in the picture as a red line.

10.6.2 Timestamp functions

NetTime-capable modules provide various timestamp functions depending on the scope of functions. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

For details, see the respective module documentation.

10.6.2.1 Time-based inputs

NetTime Technology can be used to determine the exact moment of a rising edge at an input. The rising and falling edges can also be detected and the duration between 2 events can be determined.

Information:

The determined moment always lies in the past.

10.6.2.2 Time-based outputs

NetTime Technology can be used to specify the exact moment of a rising edge on an output. The rising and falling edges can also be specified and a pulse pattern generated from them.

Information:

The specified time must always be in the future, and the set X2X Link cycle time must be taken into account for the definition of the moment.

10.6.2.3 Time-based measurements

NetTime Technology can be used to determine the exact moment of a measurement that has taken place. Both the starting and end moment of the measurement can be transmitted.

10.7 Flatstream communication

10.7.1 Introduction

B&R offers an additional communication method for some modules. "Flatstream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transfer to be handled more efficiently than with standard cyclic polling.

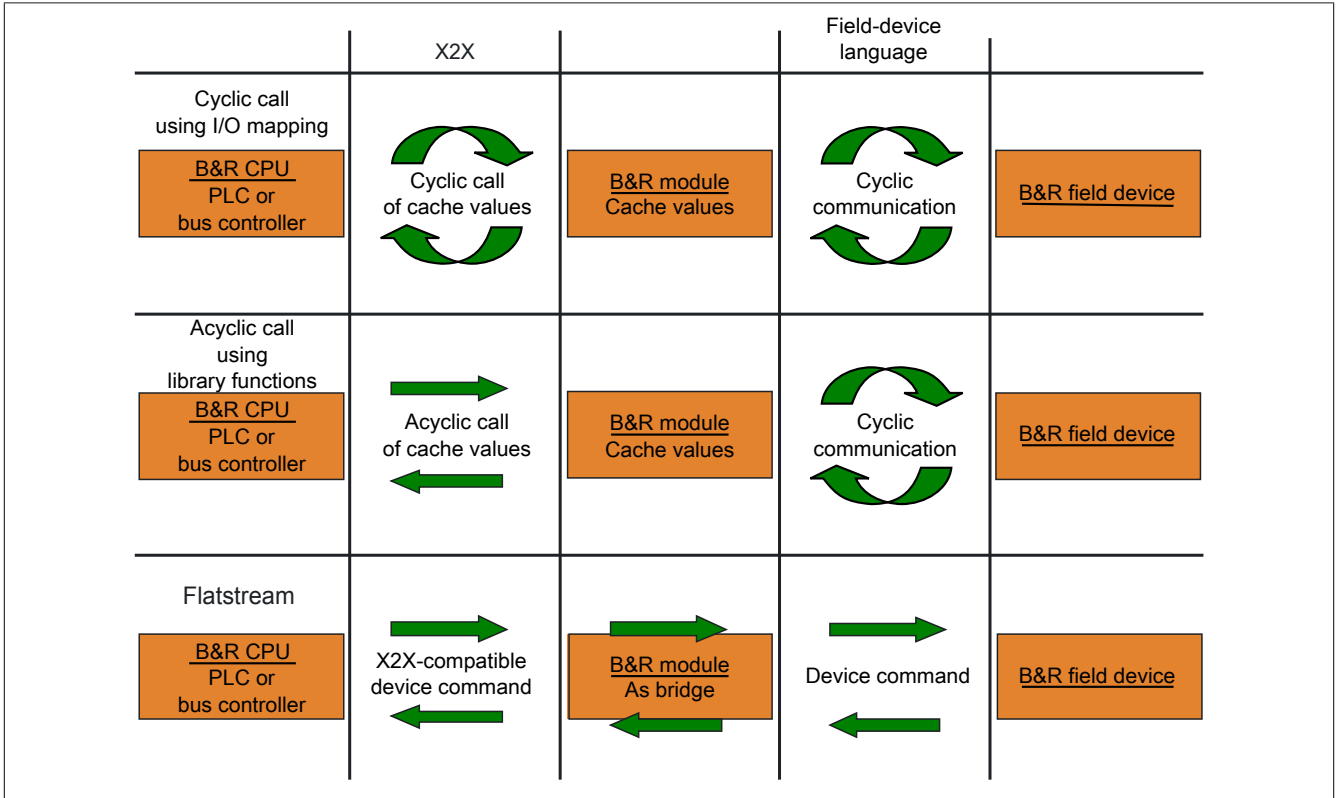

Figure 371: 3 types of communication

Flatstream extends cyclic and acyclic data queries. With Flatstream communication, the module acts as a bridge. The module is used to pass CPU queries directly on to the field device.

10.7.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With Flatstream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between 2 communicating partner stations. The length of a message is not restricted by the Flatstream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transferred segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment must be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transferred to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.

With Flatstream communication, the number of sequences sent are counted. Successfully transferred sequences must be acknowledged by the receiving station to ensure the integrity of the transfer.

MTU (Maximum Transmission Unit) - Physical transport:

MTU refers to the enabled USINT registers used with Flatstream. These registers can accept at least one sequence and transfer it to the receiving station. A separate MTU is defined for each direction of communication. OutputMTU defines the number of Flatstream Tx bytes, and InputMTU specifies the number of Flatstream Rx bytes. The MTUs are transported cyclically via the X2X Link network, increasing the load with each additional enabled USINT register.

Properties

Flatstream messages are not transferred cyclically or in 100% real time. Many bus cycles may be needed to transfer a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by register "InputSequence" or "OutputSequence".

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.

In order for communication to also take place without errors using Flatstream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.

If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses SequenceAck to determine that the transmission was faulty and that all affected sequences must be repeated.

10.7.3 The Flatstream principle

Requirement

Before Flatstream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to Flatstream conventions. This allows the Flatstream data to be organized very efficiently without having to block other important resources.

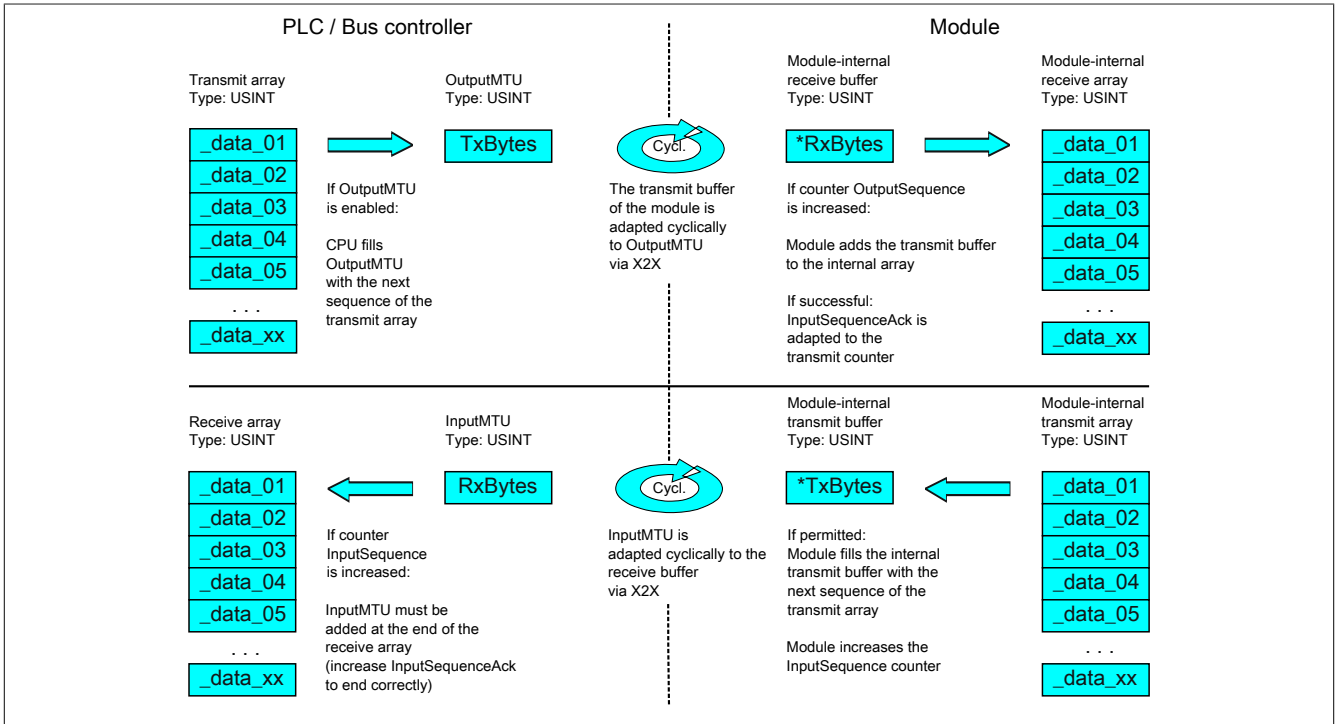

Figure 372: Flatstream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.

If the array has been completely created, the transmitter checks whether the MTU is permitted to be refilled. It then copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.

If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transfer is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transfer, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transferred.

10.7.4 Registers for Flatstream mode

5 registers are available for configuring Flatstream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via registers "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

10.7.4.1 Flatstream configuration

To use Flatstream, the program sequence must first be expanded. The cycle time of the Flatstream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, registers "InputMTU" and "OutputMTU" must be set. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transfer data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the Flatstream protocol. This functionality is useful for substantially increasing the Flatstream data rate, but it also requires quite a bit of extra work when creating the program sequence.

10.7.4.1.1 Number of enabled Tx and Rx bytes

Name:

OutputMTU

InputMTU

These registers define the number of enabled Tx or Rx bytes and thus also the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this description, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

| Data type | Values |
|-----------|---|
| USINT | See the module-specific register overview (theoretically: 3 to 27). |

10.7.4.2 Flatstream operation

When using Flatstream, the communication direction is very important. For transmitting data to a module (output direction), Tx bytes are used. For receiving data from a module (input direction), Rx bytes are used.

Registers "OutputSequence" and "InputSequence" are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transferred successfully.

10.7.4.2.1 Format of input and output bytes

Name:

"Format of Flatstream" in Automation Studio

On some modules, this function can be used to set how the Flatstream input and output bytes (Tx or Rx bytes) are transferred.

- **Packed:** Data is transferred as an array.
- **Byte-by-byte:** Data is transferred as individual bytes.

10.7.4.2.2 Transport of payload data and control bytes

Name:

TxByte1 to TxByteN

RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of registers "OutputMTU" and "InputMTU", respectively.

In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, the names were chosen from the point of view of the CPU.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

10.7.4.2.3 Control bytes

In addition to the payload data, the Tx and Rx bytes also transfer the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transferred segments.

Bit structure of a control byte

| Bit | Description | Value | Information |
|-------|---------------|--------|--|
| 0 - 5 | SegmentLength | 0 - 63 | Size of the subsequent segment in bytes (default: Max. MTU size - 1) |
| 6 | nextCBPos | 0 | Next control byte at the beginning of the next MTU |
| | | 1 | Next control byte directly after the end of the current segment |
| 7 | MessageEndBit | 0 | Message continues after the subsequent segment |
| | | 1 | Message ended by the subsequent segment |

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the set segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using option "MultiSegmentMTU".

When using Flatstream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but transferred directly after the current segment.

MessageEndBit

"MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transferred and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.

The size of the message being transferred can be calculated by adding all of the message's segment lengths together.

Flatstream formula for calculating message length:

| | | |
|---|----|---------------|
| Message [bytes] = Segment lengths (all CBs without ME) + Segment length (of the first CB with ME) | CB | Control byte |
| | ME | MessageEndBit |

10.7.4.2.4 Communication status of the CPU

Name:

OutputSequence

Register "OutputSequence" contains information about the communication status of the CPU. It is written by the CPU and read by the module.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------|-------|--|
| 0 - 2 | OutputSequenceCounter | 0 - 7 | Counter for the sequences issued in the output direction |
| 3 | OutputSyncBit | 0 | Output direction disabled |
| | | 1 | Output direction enabled |
| 4 - 6 | InputSequenceAck | 0 - 7 | Mirrors InputSequenceCounter |
| 7 | InputSyncAck | 0 | Input direction not ready (disabled) |
| | | 1 | Input direction ready (enabled) |

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

10.7.4.2.5 Communication status of the module

Name:

InputSequence

Register "InputSequence" contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------------|-------|---|
| 0 - 2 | InputSequenceCounter | 0 - 7 | Counter for sequences issued in the input direction |
| 3 | InputSyncBit | 0 | Not ready (disabled) |
| | | 1 | Ready (enabled) |
| 4 - 6 | OutputSequenceAck | 0 - 7 | Mirrors OutputSequenceCounter |
| 7 | OutputSyncAck | 0 | Not ready (disabled) |
| | | 1 | Ready (enabled) |

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

10.7.4.2.6 Relationship between OutputSequence and InputSequence

Figure 373: Relationship between OutputSequence and InputSequence

Registers "OutputSequence" and "InputSequence" are logically composed of 2 half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then SyncBit on that station must be adjusted. Before new data can be transferred, the channel must be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transferred completely are processed.

10.7.4.3 Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of SequenceCounter is stored on the station receiving the message.

Flatstream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They must be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, Flatstream cannot be used at this point in time to transfer messages from the CPU to the module.

Algorithm

| |
|--|
| 1) The CPU must write 000 to OutputSequenceCounter and reset OutputSyncBit. The CPU must cyclically query the high nibble of register "InputSequence" (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck). |
| <i>The module does not accept the current contents of InputMTU since the channel is not yet synchronized.</i> <i>The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.</i> |
| 2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is permitted to increment OutputSequenceCounter. The CPU continues cyclically querying the high nibble of register "OutputSequence" (checks for 001 in OutputSequenceAck and 0 in InputSyncAck). |
| <i>The module does not accept the current contents of InputMTU since the channel is not yet synchronized.</i> <i>The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.</i> |
| 3) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is permitted to increment OutputSequenceCounter. The CPU continues cyclically querying the high nibble of register "OutputSequence" (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). |
| Note: Theoretically, data can be transferred from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transferring data. |
| <i>The module sets OutputSyncAck.</i> |
| The output direction is synchronized, and the CPU can transmit data to the module. |

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, Flatstream cannot be used at this point in time to transfer messages from the module to the CPU.

Algorithm

| |
|---|
| <i>The module writes 000 to InputSequenceCounter and resets InputSyncBit.</i> <i>The module monitors the high nibble of register "OutputSequence" and expects 000 in InputSequenceAck and 0 in InputSyncAck.</i> |
| 1) The CPU is not permitted to accept the current contents of InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit. |
| <i>If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments InputSequenceCounter.</i> <i>The module monitors the high nibble of register "OutputSequence" and expects 001 in InputSequenceAck and 0 in InputSyncAck.</i> |
| 2) The CPU is not permitted to accept the current contents of InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit. |
| <i>If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets InputSyncBit.</i> <i>The module monitors the high nibble of register "OutputSequence" and expects 1 in InputSyncAck.</i> |
| 3) The CPU is permitted to set InputSyncAck. |
| Note: Theoretically, data could already be transferred in this cycle. If InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes must be accepted and acknowledged (see also "Communication in the input direction"). |
| The input direction is synchronized, and the module can transmit data to the CPU. |

10.7.4.4 Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet Flatstream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transferred should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

Flatstream formula for calculating the position of the next control byte:

$$\text{Position (of the next control byte)} = \text{Current position} + 1 + \text{Segment length}$$

Example

3 autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

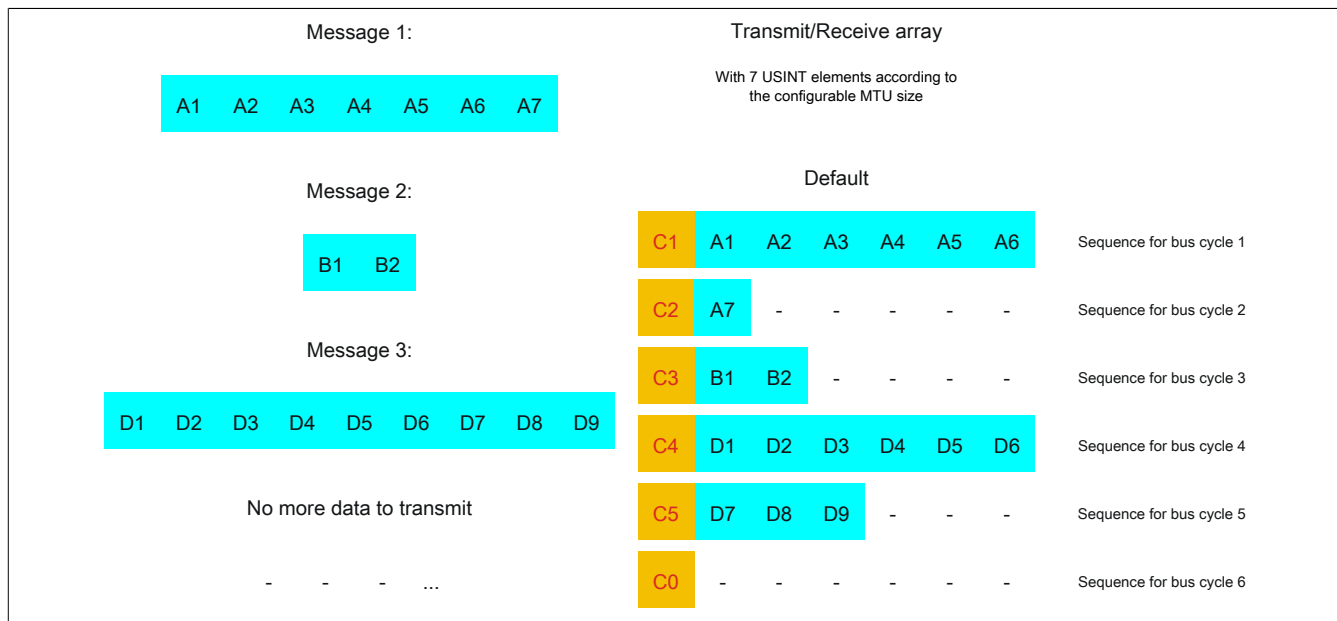

Figure 374: Transmit/Receive array (default)

Additional information

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
 - ⇒ First segment = Control byte + 6 bytes of data
 - ⇒ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
 - ⇒ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
 - ⇒ First segment = Control byte + 6 bytes of data
 - ⇒ Second segment = Control byte + 3 data bytes
- No more messages
 - ⇒ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

| C0 (control byte 0) | | C1 (control byte 1) | | C2 (control byte 2) | |
|---------------------|-----|---------------------|-----|---------------------|-------|
| - SegmentLength (0) | = 0 | - SegmentLength (6) | = 6 | - SegmentLength (1) | = 1 |
| - nextCBPos (0) | = 0 | - nextCBPos (0) | = 0 | - nextCBPos (0) | = 0 |
| - MessageEndBit (0) | = 0 | - MessageEndBit (0) | = 0 | - MessageEndBit (1) | = 128 |

Table 664: Flatstream determination of the control bytes for the default configuration example (part 2)

10.7.4.5 Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transferred one by one using Flatstream and received by the module.

Information:

Although all B&R modules with Flatstream communication always support the most compact transfers in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

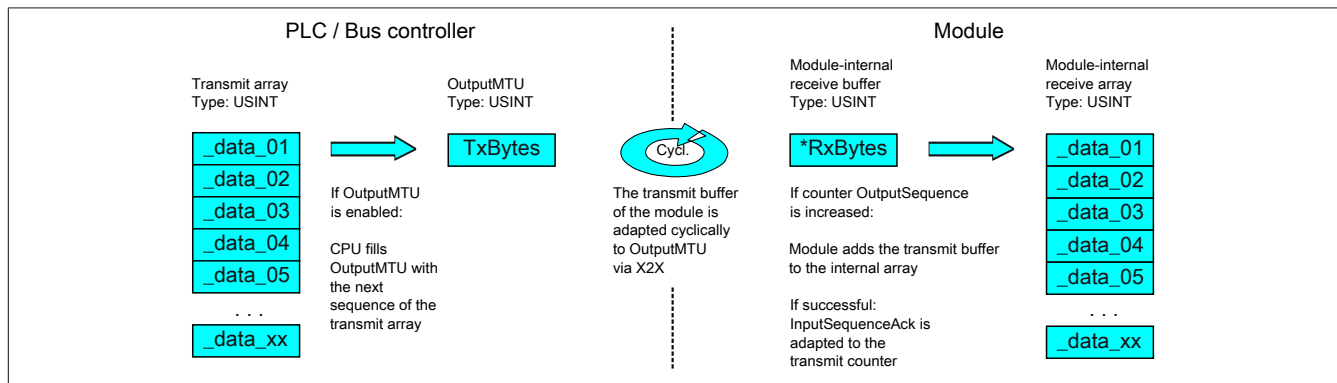

Figure 375: Flatstream communication (output)

Message smaller than OutputMTU

The length of the message is initially smaller than OutputMTU. In this case, one sequence would be sufficient to transfer the entire message and the necessary control byte.

Algorithm

Message larger than OutputMTU

The transmit array, which must be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

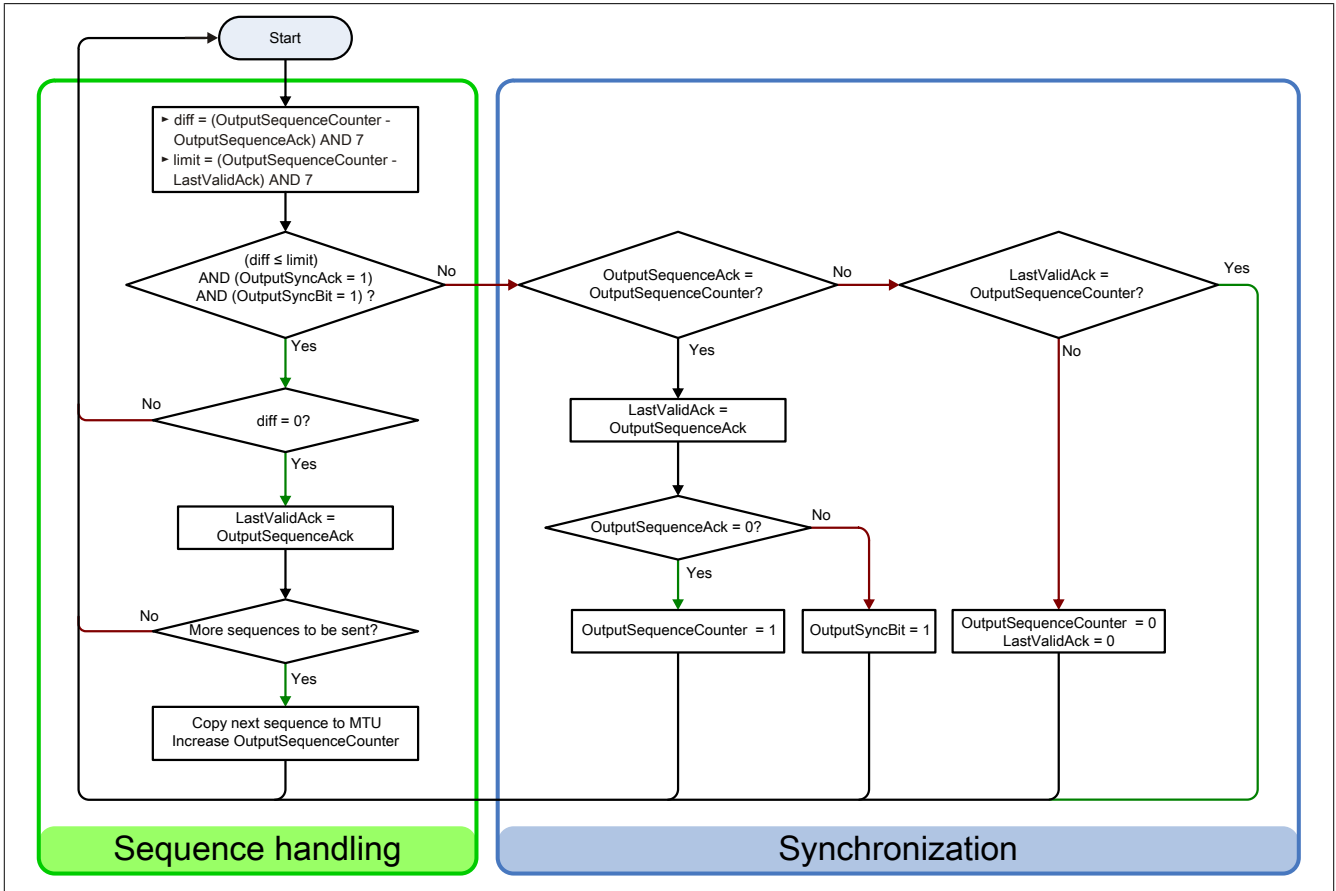

Figure 376: Flow chart for the output direction

10.7.4.6 Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via Flatstream and must then be reproduced in the receive array. The structure of the incoming data stream can be set with the mode register. The algorithm for receiving the data does not change in this regard.

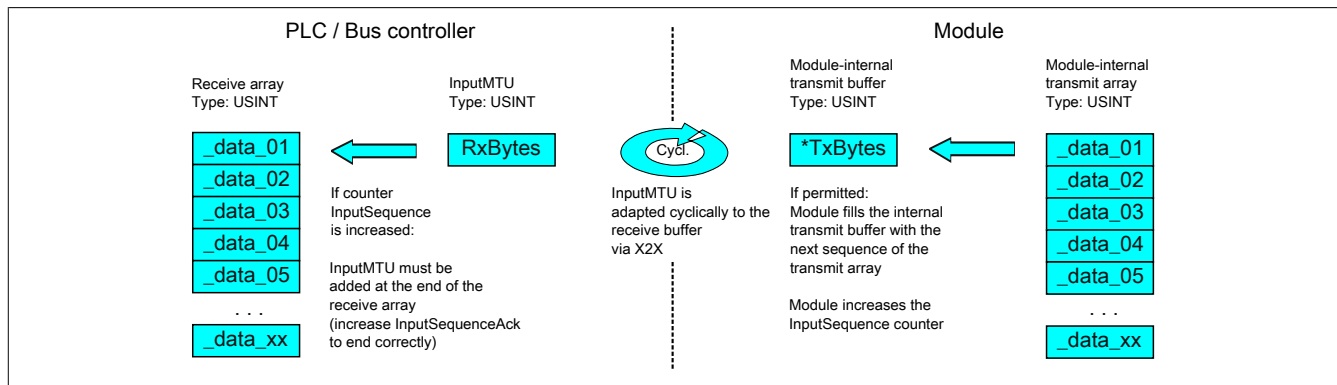

Figure 377: Flatstream communication (input)

General flow chart

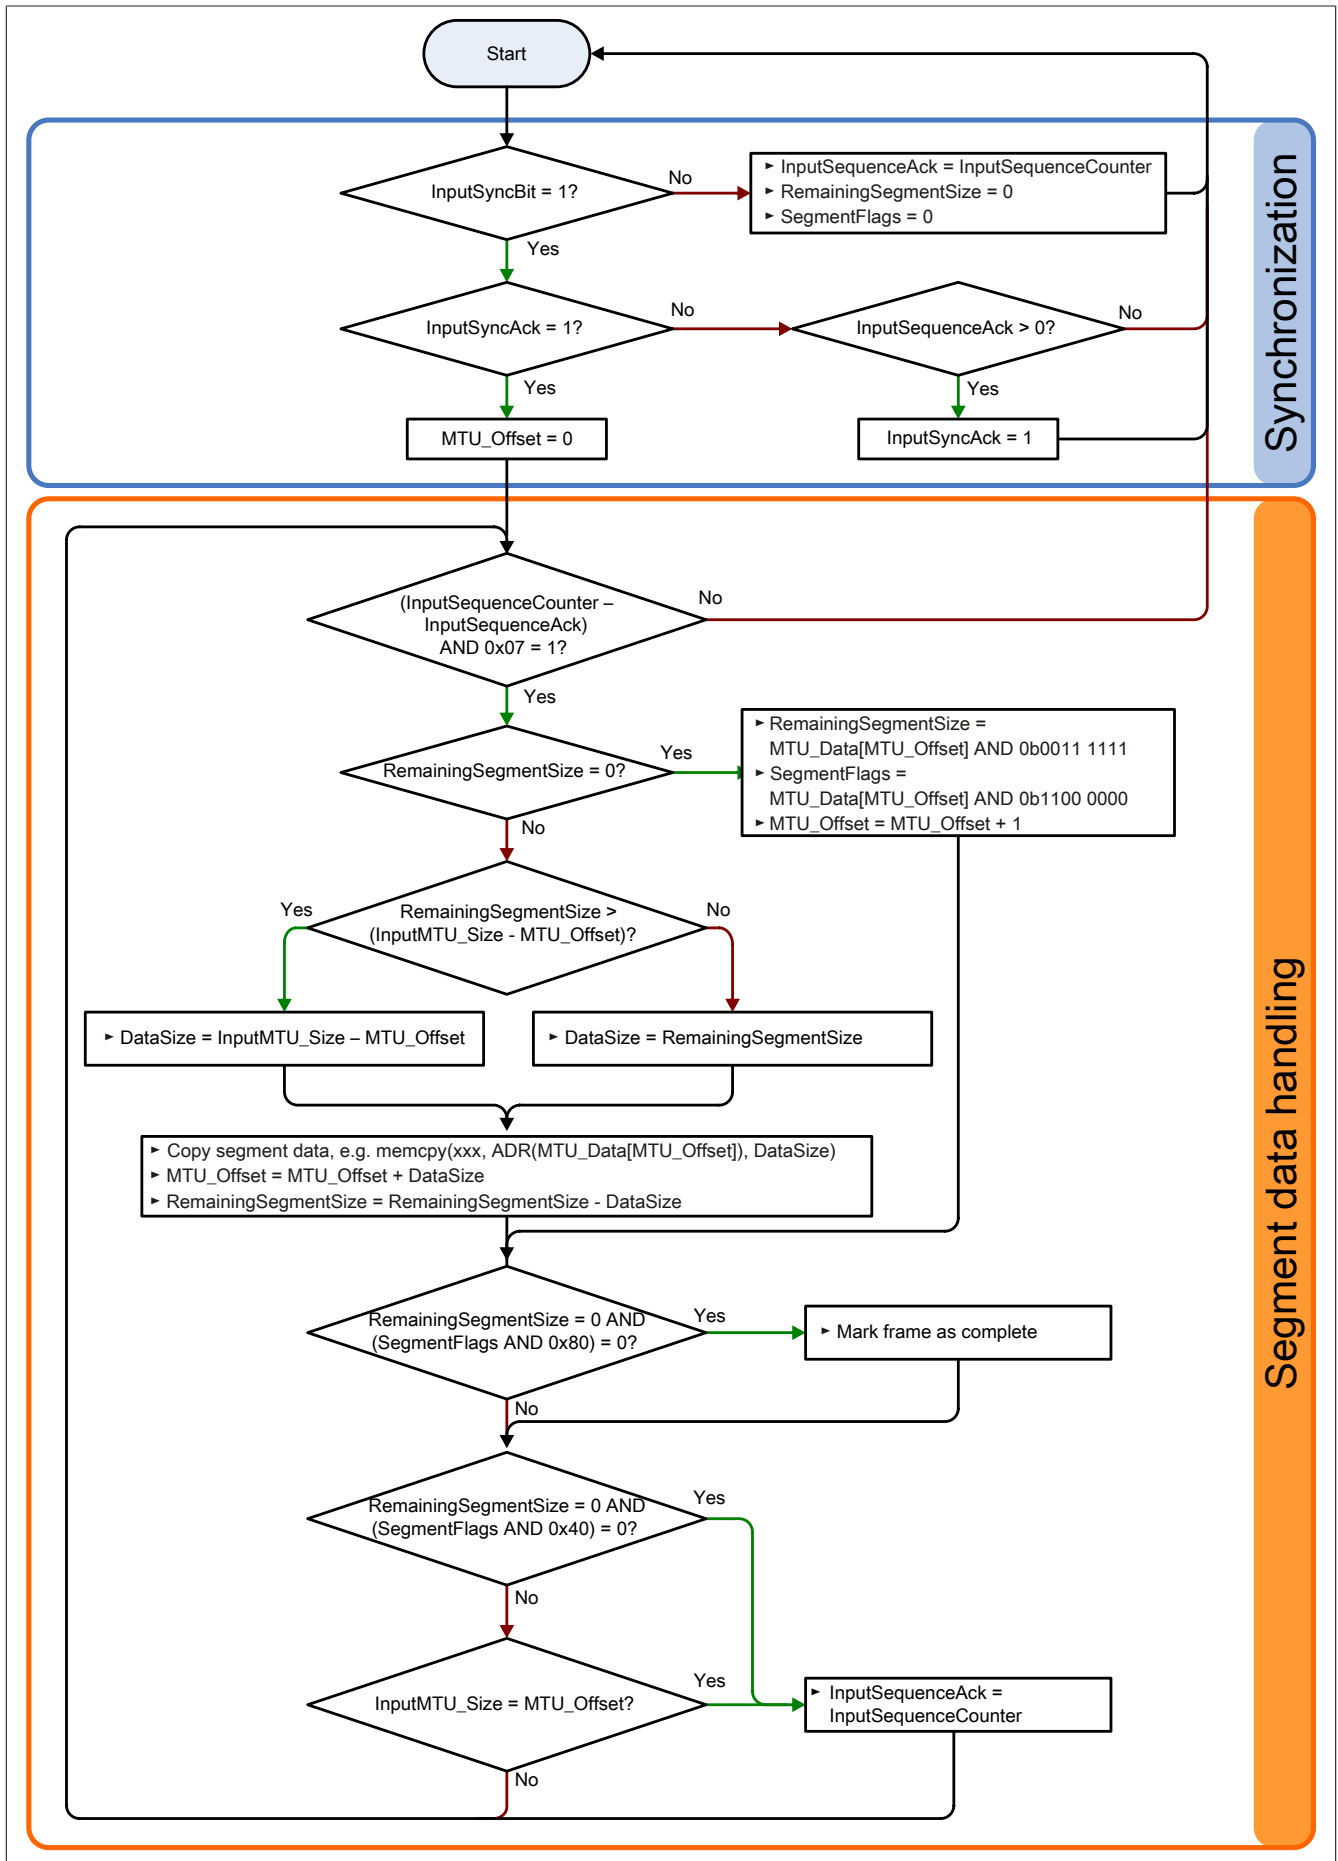

Figure 378: Flow chart for the input direction

10.7.4.7 Details

It is recommended to store transferred messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transferring with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it is important to make sure that a sufficient number of receive arrays can be managed. The acknowledge register is only permitted to be adjusted after the entire sequence has been applied.

If SequenceCounter is incremented by more than one counter, an error is present.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transferred sequence from the opposite station's SequenceAck and continue the transfer from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the value of SequenceCounter sent along with the transmission and matches SequenceAck to it. The transmitter reads SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transfer must be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It must be sent again once the channel has been resynchronized.

10.7.4.8 Flatstream mode

Name:

FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers 2 options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer Flatstream mode support options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transfer must be explicitly allowed only in the input direction.

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|-------|-----------------------|
| 0 | MultiSegmentMTU | 0 | Not allowed (default) |
| | | 1 | Permitted |
| 1 | Large segments | 0 | Not allowed (default) |
| | | 1 | Permitted |
| 2 - 7 | Reserved | | |

Standard

By default, both options relating to compact transfer in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a Flatstream message is permitted to be any length, the last segment of the message frequently does not fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

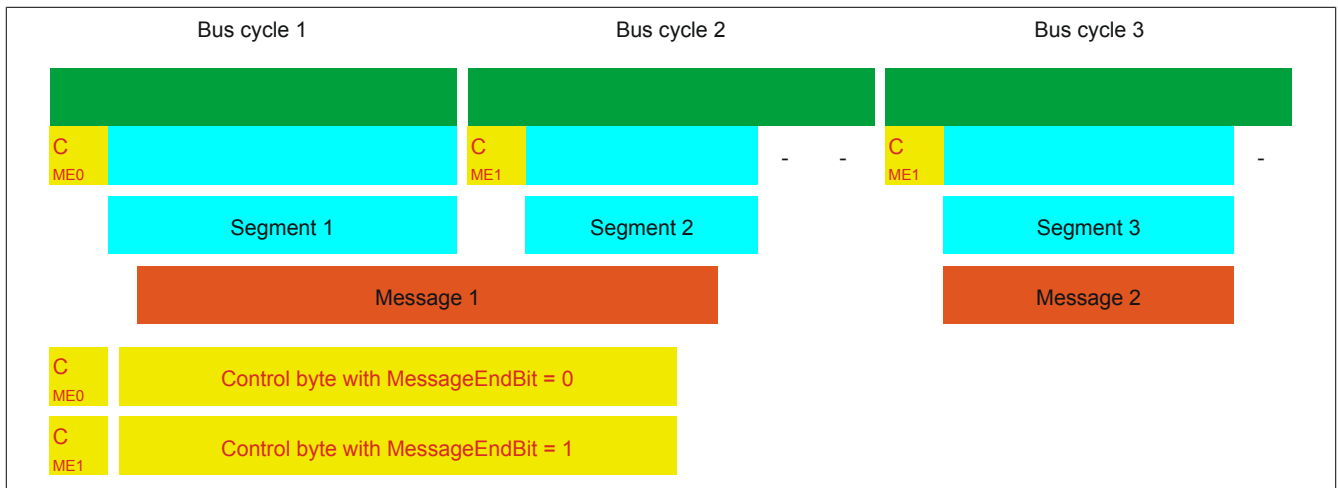

Figure 379: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transfer the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

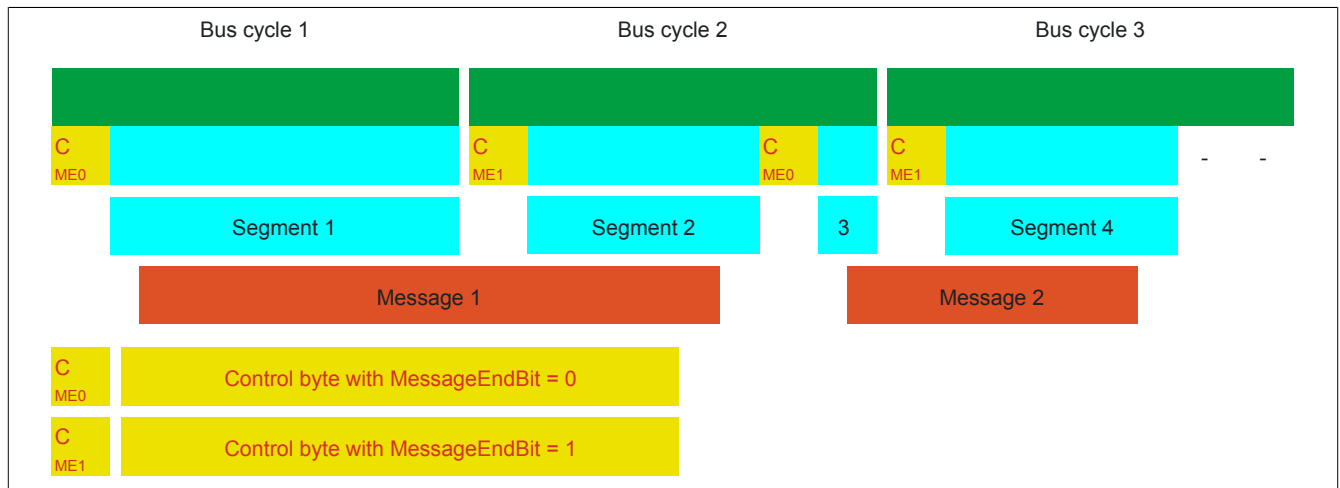

Figure 380: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transferring very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte must be created and transferred for each segment. With option "Large segments", the segment length is limited to 63 bytes independently of InputMTU. One segment is permitted to stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

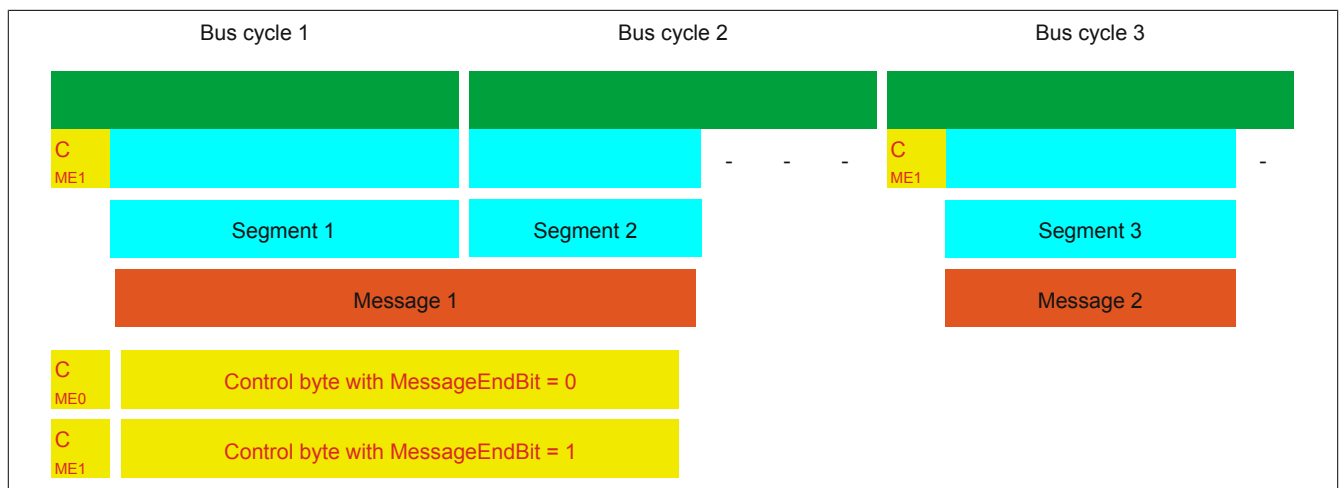

Figure 381: Arrangement of messages in the MTU (large segments)

Using both options

Using both options at the same time is also permitted.

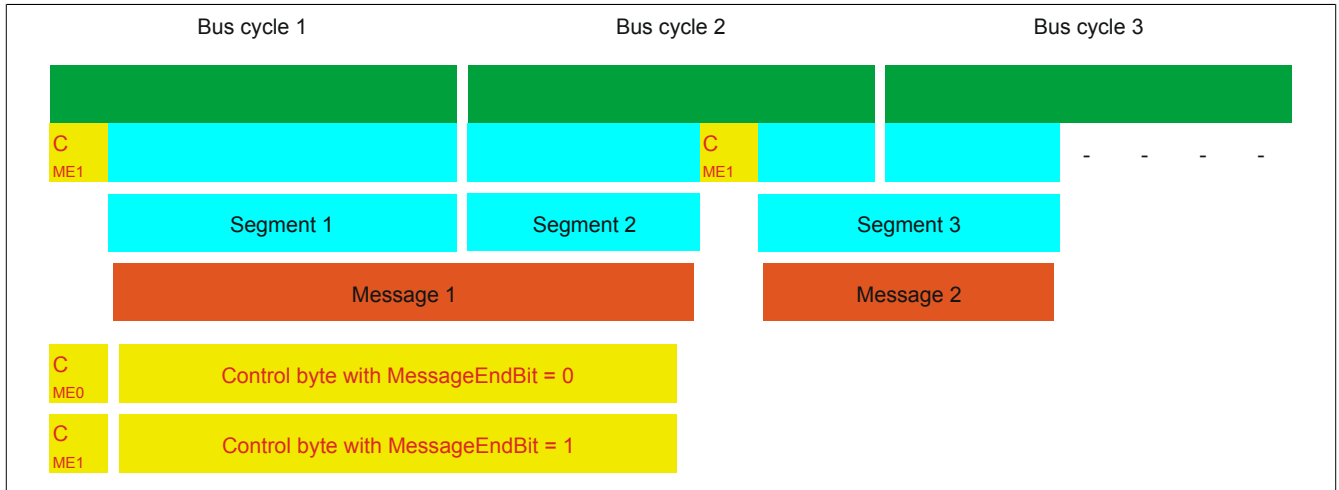

Figure 382: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

10.7.4.9 Adjusting the Flatstream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transfer the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

3 autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transfer of MultiSegmentMTUs.

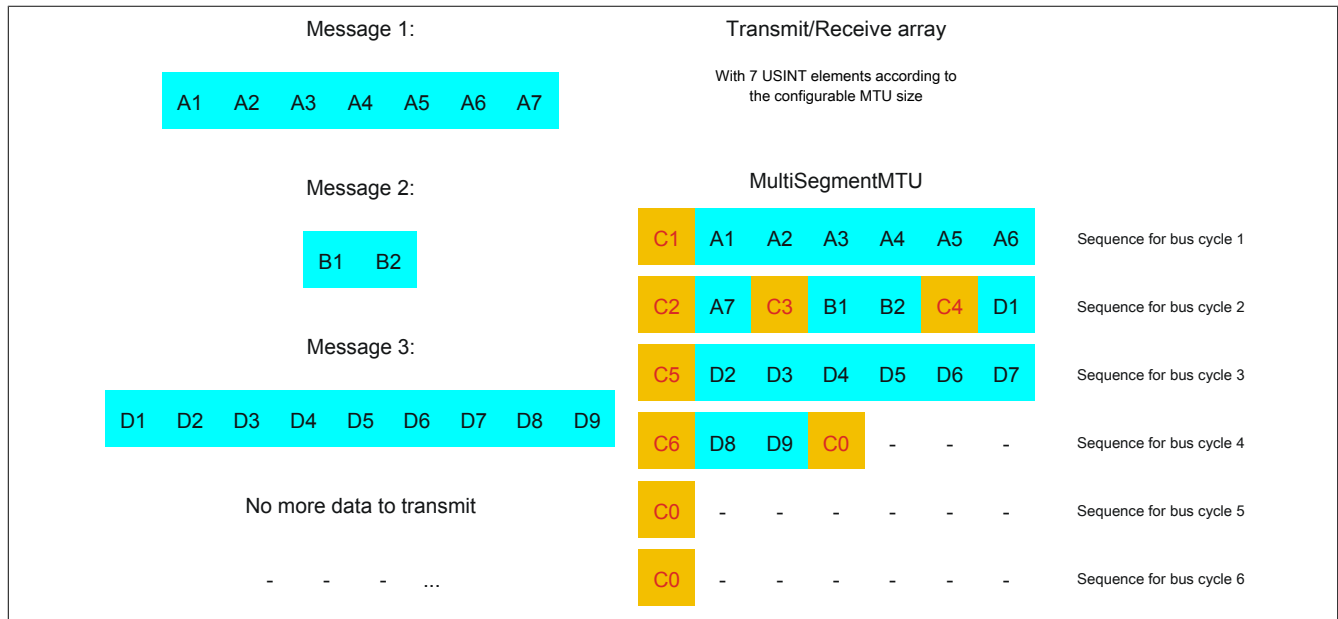

Figure 383: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is transferred after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
 - ⇒ First segment = Control byte + 6 bytes of data (MTU full)
 - ⇒ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
 - ⇒ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
 - ⇒ First segment = Control byte + 1 byte of data (MTU full)
 - ⇒ Second segment = Control byte + 6 bytes of data (MTU full)
 - ⇒ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
 - ⇒ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

| C1 (control byte 1) | | C2 (control byte 2) | | C3 (control byte 3) | |
|---------------------|------|---------------------|-------|---------------------|-------|
| - SegmentLength (6) | = 6 | - SegmentLength (1) | = 1 | - SegmentLength (2) | = 2 |
| - nextCBPos (1) | = 64 | - nextCBPos (1) | = 64 | - nextCBPos (1) | = 64 |
| - MessageEndBit (0) | = 0 | - MessageEndBit (1) | = 128 | - MessageEndBit (1) | = 128 |
| Control byte | Σ 70 | Control byte | Σ 193 | Control byte | Σ 194 |

Table 665: Flatstream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence is only permitted to be acknowledged via SequenceAck if it has been completely processed. In this example, there are 3 different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

| C4 (control byte 4) | | C5 (control byte 5) | | C6 (control byte 6) | |
|---------------------|-----|---------------------|------|---------------------|-------|
| - SegmentLength (1) | = 1 | - SegmentLength (6) | = 6 | - SegmentLength (2) | = 2 |
| - nextCBPos (6) | = 6 | - nextCBPos (1) | = 64 | - nextCBPos (1) | = 64 |
| - MessageEndBit (0) | = 0 | - MessageEndBit (1) | = 0 | - MessageEndBit (1) | = 128 |
| Control byte | Σ 7 | Control byte | Σ 70 | Control byte | Σ 194 |

Table 666: Flatstream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transferred. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

3 autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transfer of large segments.

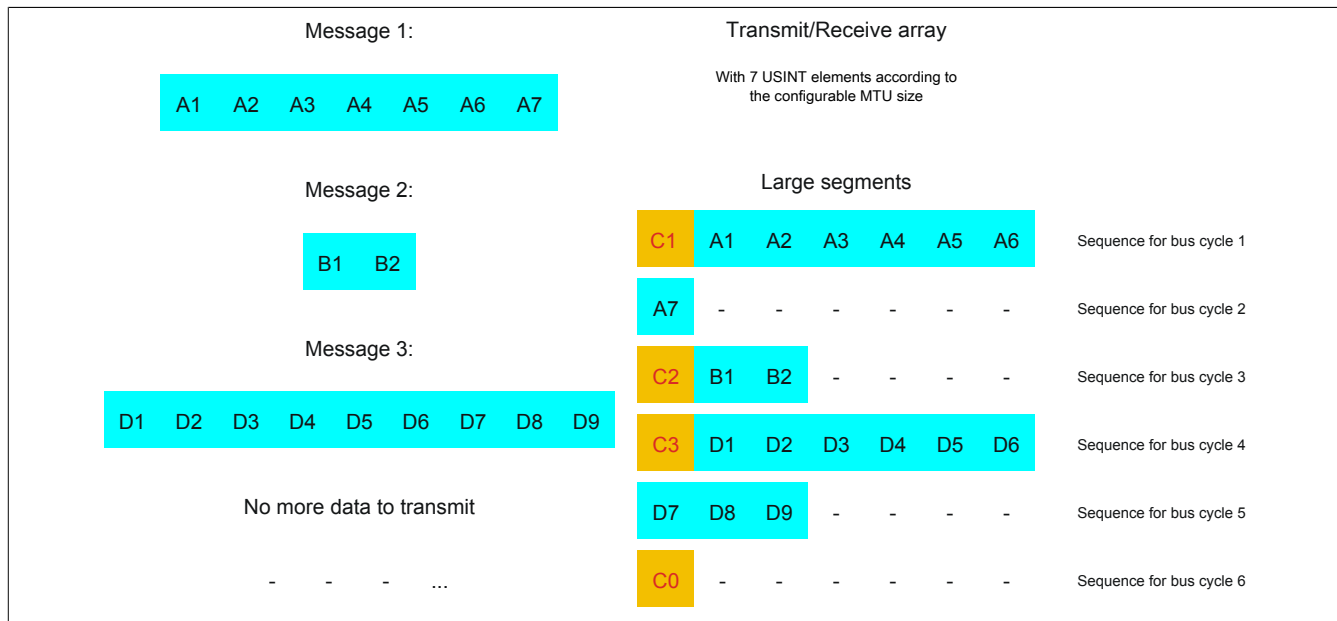

Figure 384: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)
 - ⇒ First segment = Control byte + 7 bytes of data
- Message 2 (2 bytes)
 - ⇒ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
 - ⇒ First segment = Control byte + 9 bytes of data
- No more messages
 - ⇒ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

| C1 (control byte 1) | | C2 (control byte 2) | | C3 (control byte 3) | |
|---------------------|-------|---------------------|-------|---------------------|-------|
| - SegmentLength (7) | = 7 | - SegmentLength (2) | = 2 | - SegmentLength (9) | = 9 |
| - nextCBPos (0) | = 0 | - nextCBPos (0) | = 0 | - nextCBPos (0) | = 0 |
| - MessageEndBit (1) | = 128 | - MessageEndBit (1) | = 128 | - MessageEndBit (1) | = 128 |
| Control byte | Σ 135 | Control byte | Σ 130 | Control byte | Σ 137 |

Table 667: Flatstream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

3 autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transfer of large segments as well as MultiSegmentMTUs.

Figure 385: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it is permitted to be used for other data in the data stream. Bit "nextCBPos" must always be set if the control byte belongs to a segment with payload data.

The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with option "Large segments".

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)
 - ⇒ First segment = Control byte + 7 bytes of data
- Message 2 (2 bytes)
 - ⇒ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
 - ⇒ First segment = Control byte + 9 bytes of data
- No more messages
 - ⇒ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

| C1 (control byte 1) | | C2 (control byte 2) | | C3 (control byte 3) | |
|---------------------|-------|---------------------|-------|---------------------|-------|
| - SegmentLength (7) | = 7 | - SegmentLength (2) | = 2 | - SegmentLength (9) | = 9 |
| - nextCBPos (0) | = 0 | - nextCBPos (0) | = 0 | - nextCBPos (0) | = 0 |
| - MessageEndBit (1) | = 128 | - MessageEndBit (1) | = 128 | - MessageEndBit (1) | = 128 |
| Control byte | Σ 135 | Control byte | Σ 130 | Control byte | Σ 137 |

Table 668: Flatstream determination of the control bytes for the large segment and MultiSegmentMTU example

10.7.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the Flatstream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

10.7.5.1 Function principle

X2X Link communication cycles through 5 different steps to transfer a Flatstream sequence. At least 5 bus cycles are therefore required to successfully transfer the sequence.

| | Step I | Step II | Step III | Step IV | Step V |
|-----------------|---|--|--|--|--------------------------------|
| Actions | Transfer sequence from transmit array, increase SequenceCounter | Cyclic matching of MTU and module buffer | Append sequence to receive array Adjust SequenceAck | Cyclic matching of MTU and module buffer | Check SequenceAck |
| Resource | Sender (task to transmit) | Bus system (direction 1) | Recipient (task to receive) | Bus system (direction 2) | Sender (task for Ack checking) |

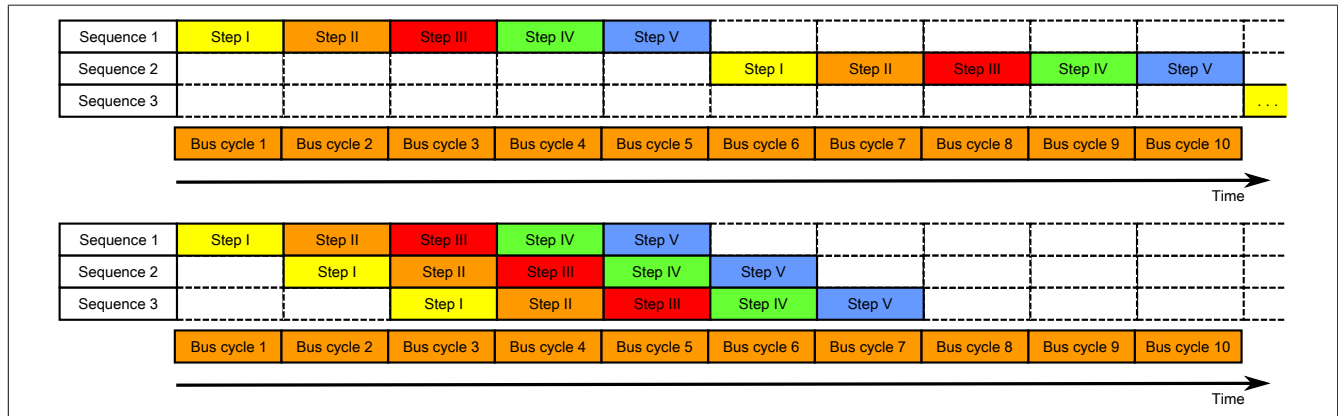

Figure 386: Comparison of transfer without/with Forward

Each of the 5 steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.

With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.

In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transferred successfully.

10.7.5.2 Configuration

The Forward function must only be enabled for the input direction. 2 additional configuration registers are available for doing so. Flatstream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of OutputMTU is specified.

10.7.5.2.1 Number of unacknowledged sequences

Name:
Forward

With register "Forward", the user specifies how many unacknowledged sequences the module is permitted to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

| Data type | Values |
|-----------|----------------------|
| USINT | 1 to 7 Default: 1 |

10.7.5.2.2 Delay time

Name:
ForwardDelay

Register "ForwardDelay" is used to specify the delay time in μs . This is the amount of time the module has to wait after sending a sequence until it is permitted to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

| Data type | Values |
|-----------|--|
| UINT | 0 to 65535 [μs] Default: 0 |

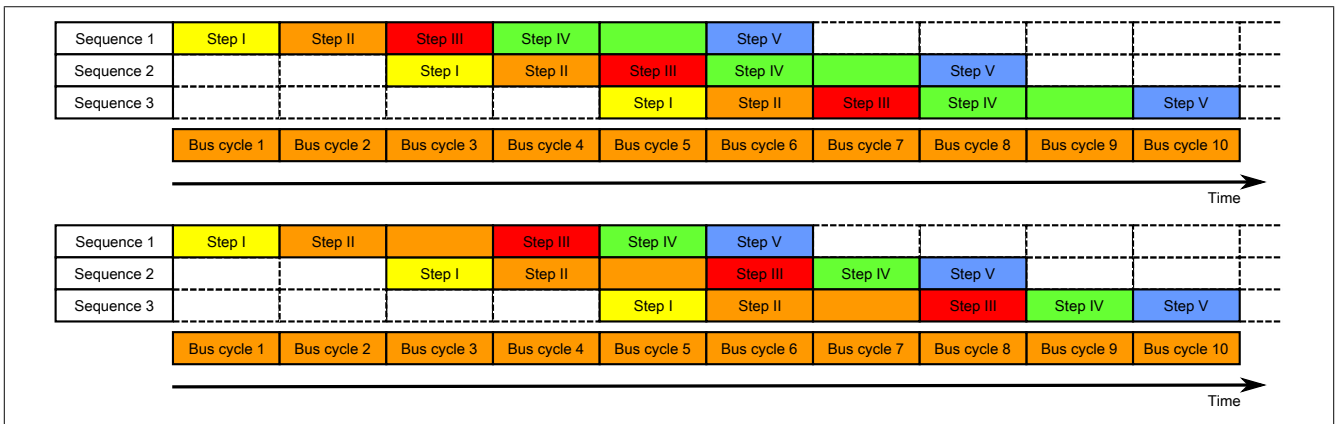

Figure 387: Effect of ForwardDelay when using Flatstream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

10.7.5.3 Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to 7 unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Details/Background

1. Illegal SequenceCounter size (counter offset)

Error situation: MTU not enabled

If the difference between SequenceCounter and SequenceAck during transmission is larger than permitted, a transfer error occurs. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.

2. Checking an acknowledgment

After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence is acknowledged multiple times, a severe error occurs. The channel must be closed and resynchronized (same behavior as when not using Forward).

Information:

In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.

An error does not occur in this case. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transferred successfully.

3. Transmit and receive arrays

The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

10.7.5.4 Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transfers if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transferred.

Using Forward functionality with Flatstream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transferred properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transferred successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and causes the value of SequenceCounter and/or the filled MTU to be lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.

The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only permitted to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.

If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

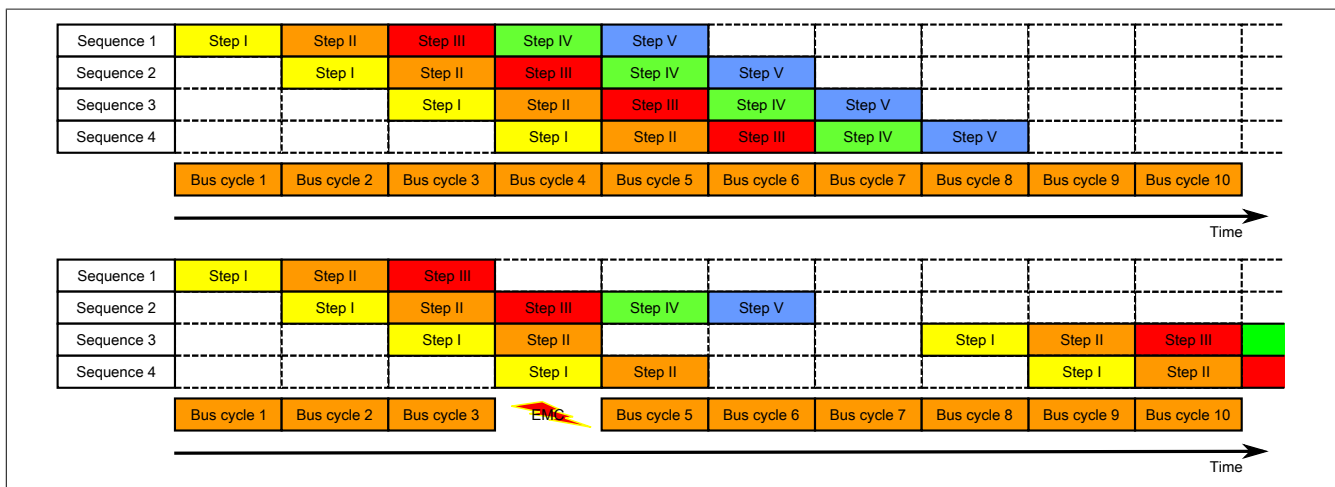

Figure 388: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.

The transmitting station continues transmitting until it has issued the maximum permissible number of unacknowledged transmissions.

5 bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.
