The source for the sample cycle is configured in this register. During each sample cycle, one bit from the output control buffers of the oversampled I/O channels is output to the configured physical output, and the status of the configured inputs is read into one bit of the respective input status buffer.

| Data type | Values | Information |
|-----------|--------|---|
| USINT | 2 | System timer The value set in register " CfO_SystemCycleTime " on page 1971 is used as the sample cycle. |
| | 3 | Prescaled system timer The "prescaled system timer" is used as sample cycle. |
| | 10 | AOAI The sample cycle is clocked with the AOAI interrupt of the X2X cycle. |
| | 14 | SOSI The sample cycle is clocked with the SOSI interrupt of the X2X cycle. |

9.16.5.11.9.4 Configuration of the source for the user interface reference cycle

Name:

CfO_OversampleRelativeCycleID

"Reference cycle" in the Automation Studio I/O configuration.

The source for the user interface reference cycle is configured in this register.

- The input data is referenced at the moment of the reference cycle. The referenced data is then copied to the "oversample input sample register" on page 1981 at the moment of SI frame generation, taking into account the oversample input window.
- With relative addressing of the output control buffer, the new sample data is copied to an address relative to the output control buffer address current to the "reference cycle".
- The reference cycle is also used to reference the sample cycle and thus the output data production and input data acquisition (e.g. to the X2X cycle).

| Data type | Values | Information |
|-----------|--------|--|
| USINT | 2 | System timer The value set in register "CfO_SystemCycleTime" on page 1971 is used as the reference cycle. |
| | 3 | Prescaled system timer The prescaled system timer is used as sample cycle. |
| | 10 | AOAI The sample cycle is referenced with the AOAI interrupt of the X2X cycle. |
| | 14 | SOSI The sample cycle is referenced with the SOSI interrupt of the X2X cycle. |

9.16.5.11.9.5 Defining the moment for copying the data to the output control buffer

Name:

CfO_OversampleConsumeCycleID

"Output copy cycle" in the Automation Studio I/O configuration.

At the time of the output copy cycle, data is copied from the "OversampleOutput0NSample" on page 1980 registers into the output control buffer.

When "Output copy cycle = Fast reaction", it is not possible to determine when the data is copied to the output control buffer in either of the two addressing modes. The copy cycles will experience a certain degree of jitter depending on the module load. However, this only affects the moment of the internal copy procedures and therefore the moment of the earliest possible output sample. This will not affect the quality of the output signal. However, "Output copy cycle = Fast reaction" also has a negative effect on the minimum X2X cycle time.

When using the setting "Output copy cycle = X2X cycle optimized", be aware that the sample data cannot start being output immediately at the "Output copy cycle" time due to the internal copy cycle to the output control buffers.

| Data type | Values | Information |
|-----------|--------|---|
| USINT | 10 | X2X cycle optimized The output data is copied to the output control buffer with the AOAI interrupt of the X2X cycle. |
| | 15 | Fast reaction The output data is copied to the output control buffer immediately after being received. |

9.16.5.11.9.6 Number of output bits to be transferred

Name:

CfO_OversampleOutputBits

"User interface size" in the Automation Studio I/O configuration.

Specifies how many bits are transferred from the "OversampleOutput0NSample" on page 1980 registers to the output control buffers at the output copy cycle moment.

| Data type | Values | Information |
|-----------|---------|-------------|
| USINT | 1 to 64 | Output bits |

9.16.5.11.9.7 Number of input bits to be transferred

Name:

CfO_OversampleInputBits

"User interface size" in the Automation Studio I/O configuration.

Specifies how many bits are transferred from the input status buffer to the "OversampleInput0NSample" on page 1981 registers during SI frame generation.

| Data type | Values | Information |
|-----------|---------|-------------|
| USINT | 1 to 64 | Input bits |

9.16.5.11.9.8 Write area in the output control buffer

Name:

CfO_OversampleOutputWindow

"Output control mode" in the Automation Studio I/O configuration.

Defines the area in the output control buffer to which data is permitted to be written. The window is always offset relative to the current sample position. (a value of 128, for example, means that the 128 bits following the current sample cycle can be written to). An [OutputCopyError](#) is triggered if an attempt is made to write output sample data to a location outside of this window.

In Automation Studio, the value for this register is set to 128 bits with "Output control mode = Single" and to 255 bits with "Output control mode = Continuous".

| Data type | Values | Information |
|-----------|----------|---------------|
| USINT | 0 to 255 | Output window |

9.16.5.11.9.9 Defining the moment for referencing input data

Name:

CfO_OversampleInputWindow

"Input mode" in the Automation Studio I/O configuration.

The "oversample input window" defines when the input data is referenced. It is located chronologically before [SI frame generation](#). If the reference moment ("reference cycle" on page 1977) is within this window, then the referenced data from the input status buffer is copied to register "OversampleInput0NSample" on page 1981. If the moment at which the reference occurs is outside the "oversample input window" then the data that is most recent at the moment of "SI frame generation" is copied from the input status buffer to register "OversampleInput0NSample" on page 1981.

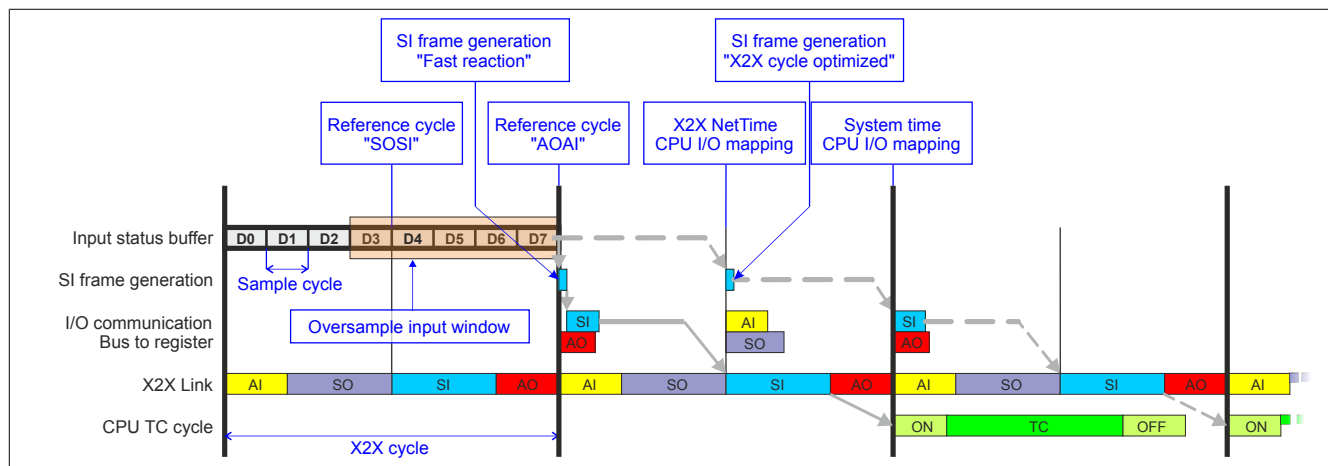

This register is limited internally to the value from register "CfO_OversampleInputBits" on page 1977.

Information:

As a result, the [oversample input time](#) and [oversample input cycle](#) are set either at the reference time or at the moment of "SI frame generation".

In Automation Studio, the value for this register is set to 63 with "Input mode = Referenced values" and to 0 with "Input mode = Most recent values".

| Data type | Values | Information |
|-----------|---------|--------------|
| USINT | 0 to 63 | Input window |

9.16.5.11.9.10 Assigning between the physical input channel and oversample I/O input

Name:

CfO_OversampleConfigInput

"Oversample I/O 01 → Input" to "Oversample I/O 04 input" in the Automation Studio I/O configuration.

Which physical input channel an oversample I/O input should be linked to is defined in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------------------|-------|-----------------|
| 0 - 3 | Number of the physical input channel | 0 | Input channel 1 |
| | | .. | |
| | | 7 | Input channel 8 |
| 4 - 7 | Reserved | - | |

9.16.5.11.9.11 Configuring the outputs of the oversampling channels

Name:

CfO_OversampleConfigOutput

"Oversample I/O 01 → Output" to "Oversample I/O 04 → Output" in the Automation Studio I/O configuration

"Oversample I/O 01 → Output control" to "Oversample I/O 04 → Output control" in the Automation Studio I/O configuration

"Oversample I/O 01 → Output default value" to "Oversample I/O 04 → Output default value" in the Automation Studio I/O configuration

This register helps configure the outputs of the individual oversample channels.

The "Output default state" bits define which level the respective output takes on before oversampling is started. In addition, the output is set to the defined "Output default state" in the event of an error.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---|-------|---|
| 0 - 3 | Number of the physical output channel "Oversample I/O 0x → Output" | 2 | Output channel 3 |
| | | 3 | Output channel 4 |
| | | 6 | Output channel 7 |
| | | 7 | Output channel 8 |
| 4 | Output: Clear "Oversample I/O 0x → Output control" | 0 | Output cannot be reset by the oversample channel. |
| | | 1 | Output can be reset by the oversample channel. |
| 5 | Output: Set "Oversample I/O 0x → Output control" | 0 | Output cannot be set by the oversample channel. |
| | | 1 | Output can be set by the oversample channel. |
| 6 | Default output state: Clear "Oversample I/O 0x → Output default value" | 0 | Output not cleared by default |
| | | 1 | Output cleared by default |
| 7 | Default output state: Set "Oversample I/O 0x → Output default value" | 0 | Output not set by default |
| | | 1 | Output set by default |

9.16.5.11.9.12 Oversampling configuration

Name:

OversampleEnable

OversampleOutputValidate

The oversampling and copy process for the output buffer can be configured in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------|-------|--|
| 0 | OversampleEnable | 0 | Disables oversampling (with the next reference cycle) |
| | | 1 | Enables oversampling (with the next reference cycle) |
| 1 | OversampleOutputValidate | 0 | Disable the copy procedure to the output control buffer. |
| | | 1 | Enables the copy procedure to the output control buffer. <ul style="list-style-type: none"> Used to synchronize the oversampling procedure at startup. This makes it possible to prevent new data from being transferred to the "OversampleOutput0NSample" on page 1980 registers in each X2X cycle. |
| 2 - 7 | Reserved | - | |

9.16.5.11.9.13 Address of the new output sampling data in the output control buffer

Name:

OversampleOutputCycle

When absolute addressing of the output control buffer is being used, this register specifies the address from which the new output sample data should be copied to the output control buffer.

| Data type | Values | Information |
|-----------|----------|--------------------------------------|
| USINT | 0 to 255 | Address of the output control buffer |

9.16.5.11.9.14 Offset of new output sample data

Name:

OversampleSampleOffset

When relative addressing of the output control buffer is being used, this register serves as the offset for the new output sample data. (Sample address at the time of the [reference cycle](#) + Offset = Address to which the new output sample data is copied in the output control buffer).

| Data type | Values | Information |
|-----------|----------|------------------------------|
| USINT | 0 to 255 | Offset of output sample data |

9.16.5.11.9.15 Oversample output sample data

Name:

OversampleOutput01Sample1_8 to OversampleOutput04Sample1_8
 OversampleOutput01Sample9_16 to OversampleOutput04Sample9_16
 OversampleOutput01Sample17_24 to OversampleOutput04Sample17_24
 OversampleOutput01Sample25_32 to OversampleOutput04Sample25_32
 OversampleOutput01Sample33_40 to OversampleOutput04Sample33_40
 OversampleOutput01Sample41_48 to OversampleOutput04Sample41_48
 OversampleOutput01Sample49_56 to OversampleOutput04Sample49_56
 OversampleOutput01Sample57_64 to OversampleOutput04Sample57_64

Contains the oversample output sample data. Up to 64 samples (8 bytes) for each oversample I/O channel can be synchronously transferred with a X2X cycle. This data is copied to the specified address (absolute or relative) in the output control buffer at the set [output copy cycle](#). 1 bit of this data is then output during each "sample cycle" to the physical output that is assigned to the oversample I/O channel.

Bit 0 of "OversampleOutputSample8_1" is copied to the output control buffer first, meaning that it is the first bit that is output. "OversampleOutputSample64_57" bit 7 is the last bit to be output.

| Data type | Values | Information |
|-----------|----------|--------------------|
| USINT | 0 to 255 | Output sample data |

Example

Assignment of "OversampleOutputSample" register data to output signal

**9.16.5.11.9.16 X2X NetTime of the input data**

Name:

OversampleInputTime

This register contains the 2 low-order bytes of the X2X NetTime from the moment at which the oversample input data was referenced. This provides an easy way to accurately calculate the moment of each individual input sample.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Values | Information |
|-----------|-----------------|---|
| INT | -32768 to 32767 | X2X NetTime of the input data in microseconds |

9.16.5.11.9.17 Input status buffer address of the input sample data

Name:

OversampleInputCycle

This register contains the input status buffer address of the input sample data.

In addition, the value in this register can be used to reference an absolute addressing of the output control buffer.

| Data type | Values | Information |
|-----------|----------|-----------------------------|
| USINT | 0 to 255 | Input status buffer address |

9.16.5.11.9.18 Input sample data

Name:

OversampleInput01Sample8_1 to OversampleInput04Sample8_1

OversampleInput01Sample16_9 to OversampleInput04Sample16_9

OversampleInput01Sample24_17 to OversampleInput04Sample24_17

OversampleInput01Sample32_25 to OversampleInput04Sample32_25

OversampleInput01Sample40_33 to OversampleInput04Sample40_33

OversampleInput01Sample48_41 to OversampleInput04Sample48_41

OversampleInput01Sample56_49 to OversampleInput04Sample56_49

OversampleInput01Sample64_57 to OversampleInput04Sample64_57

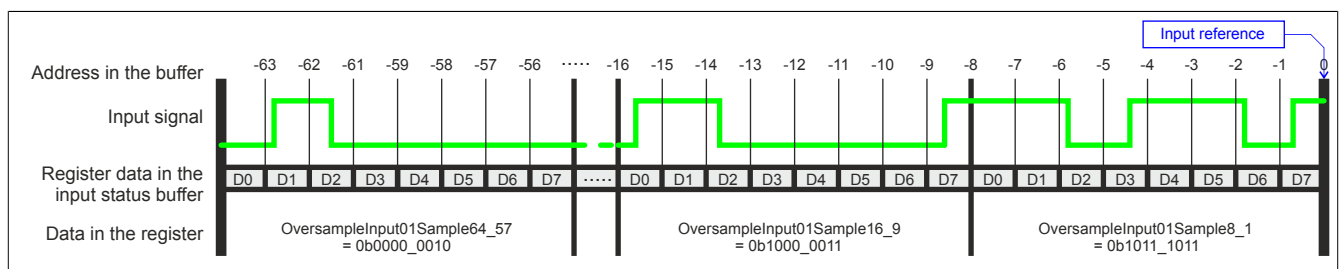

The data of the 4 oversample input status buffers are copied to this register at the moment of **SI frame generation**. A maximum of 64 samples (8 bytes) per oversample I/O channel can be synchronously retrieved from the oversample input status buffer with each X2X cycle.

The most recent input sample bit is stored in "OversampleInputSample8_1" bit 7. The oldest input sample is stored in "OversampleInputSample64_57" bit 0.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Input sample data |

Example

Input signal and resulting data in "OversampleInputSample"

9.16.5.11.10 Edge detection

The module's edge detection function allows edges to be measured with microsecond precision. The concept is based on a maximum of 4 units. One master and one slave edge can be configured for each unit.

At the moment of each master edge, the **NetTime** of the master edge and the **NetTime** of a previous slave edge (if present) are logged. A "master counter" and a "slave counter" can always be used to determine how many edges have been detected since the last X2X cycle.

9.16.5.11.10.1 Configuring the source for the polling cycle

Name:

CfO_EdgeDetectPollCycleID

"Polling cycle" in the Automation Studio I/O configuration.

The source for the polling cycle can be configured in this register.

Information:

The polling cycle must be $\leq 255 \mu\text{s}$. If the configured cycle $> 255 \mu\text{s}$, **EdgeDetectError** occurs.

| Data type | Values | Information |
|-----------|--------|---|
| USINT | 2 | System timer The time set in register "CfO_SystemCycleTime" on page 1971 is used for the polling cycle. |
| | 3 | Prescaled system timer The time set in register "CfO_SystemCyclePrescaler" on page 1971 is used for the polling cycle. |

9.16.5.11.10.2 Edge detection mode

Name:

CfO_EdgeDetectEventEnable

"Edge detection mode" in the Automation Studio I/O configuration.

The bits in this register define on which edges of the individual input channels an interrupt should be triggered for edge detection.

In mode "Event-triggered", the [NetTime](#) of each edge is recorded immediately as interrupt. However, an extremely large amount of interrupts within a short amount of time can prevent the module from being able to process any other operations in time!

In mode "Polling", only the [NetTime](#) of the first edge that occurs within a polling cycle is recorded. This ensures that the module is not overloaded by too many edges.

In the Automation Studio I/O configuration, this register is initialized with 0x00000000 when "Edge detection mode = Polling" and with 0xFFFFFFFF when "Edge detection mode = Event-triggered".

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|------------------|-------|--|
| 0 | Physical input 1 | 0 | No interrupt triggered on falling edge |
| | | 1 | Interrupt triggered on falling edge |
| ... | | ... | |
| 7 | Physical input 8 | 0 | No interrupt triggered on falling edge |
| | | 1 | Interrupt triggered on falling edge |
| 8 - 15 | Reserved | - | |
| 16 | Physical input 1 | 0 | No interrupt triggered on rising edge |
| | | 1 | Interrupt triggered on rising edge |
| ... | | ... | |
| 23 | Physical input 8 | 0 | No interrupt triggered on rising edge |
| | | 1 | Interrupt triggered on rising edge |
| 24 - 31 | Reserved | - | |

9.16.5.11.10.3 Setting the time base, slave edge and master edge

Name:

CfO_EdgeDetectUnit01Mode to CfO_EdgeDetectUnit04Mode

"Time base" in the Automation Studio I/O configuration

"Slave edge" in the Automation Studio I/O configuration

"Master edge" in the Automation Studio I/O configuration

When using a time base with 1/8 μ s resolution, keep in mind that the timestamps produced also have a resolution of exactly 1/8 μ s. The respective conversions must be made for calculating in combination with the CPU system time or [X2X NetTime](#).

In addition, synchronization jitter also plays a role when using "Time base = Nettime resolution 1/8 usec" (see "[Synchronization jitter](#)" on page 1966). This means that exactly identical input edges can cause slight differences in the results. If 100% exact 1/8 μ s resolution is required, then "Local resolution 1/8 usec" must be used.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------|-------|---|
| 0 - 1 | "Time base" | 0 | Local time 1/8 μ s (Automation Studio: Local resolution 1/8 usec) |
| | | 1 | Local time 1 μ s (Automation Studio: Local resolution 1 usec) |
| | | 2 | NetTime 1/8 μ s (Automation Studio: Nettime resolution 1/8 usec) |
| | | 3 | NetTime 1 μ s (Automation Studio: Nettime resolution 1 usec) |
| 2 - 5 | Reserved | - | |
| 6 | "Slave edge" | 0 | Disabled |
| | | 1 | Enabled |
| 7 | "Master edge" | 0 | Disabled |
| | | 1 | Enabled |

9.16.5.11.10.4 Load position of the slave time from the FIFO buffer

Name:

CfO_EdgeDetectUnit01Leading to CfO_EdgeDetectUnit04Leading

"Slave leading" in the Automation Studio I/O configuration.

When a slave edge occurs, the current **NetTime** is always saved within the module. A FIFO buffer is provided inside the module that always stores the last 256 slave stamps (even when a master edge occurs).

This value defines the position from which the slave time should be retrieved from the FIFO buffer when a master edge occurs. This can be used to measure average periodic signals over multiple cycles.

| Data type | Values | Information |
|-----------|----------|---|
| USINT | 0 to 255 | Position in the FIFO buffer for slave edges |

9.16.5.11.10.5 Source of the master edge per edge detection unit

Name:

CfO_EdgeDetectUnit01Master to CfO_EdgeDetectUnit01Master

"Master edge" in the Automation Studio I/O configuration.

The source of the master edge for the respective "edge detection unit" is defined in this register.

| Data type | Values | Information |
|-----------|--------|----------------------------------|
| USINT | 0 | Rising edge on physical input 1 |
| | ... | ... |
| | 7 | Rising edge on physical input 8 |
| | 16 | Falling edge on physical input 1 |
| | ... | ... |
| | 23 | Falling edge on physical input 8 |

9.16.5.11.10.6 Source of the slave edge per edge detection unit

Name:

CfO_EdgeDetectUnit01Slave to CfO_EdgeDetectUnit04Slave

"Slave edge" in the Automation Studio I/O configuration.

The source of the slave edge for the respective "edge detection unit" is defined in this register.

| Data type | Values | Information |
|-----------|--------|----------------------------------|
| USINT | 0 | Rising edge on physical input 1 |
| | ... | ... |
| | 7 | Rising edge on physical input 8 |
| | 16 | Falling edge on physical input 1 |
| | ... | ... |
| | 23 | Falling edge on physical input 8 |

9.16.5.11.10.7 Number of detected master edges

Name:

EdgeDetect01Mastercount to EdgeDetect04Mastercount

Detected master edges are counted in this register.

| Data type | Values | Information |
|-----------|-----------------|--|
| SINT | -128 to 127 | Number of detected master edges (8-bit) |
| INT | -32768 to 32767 | Number of detected master edges (16-bit) |

9.16.5.11.10.8 Number of detected slave edges

Name:

EdgeDetect01Slavecount to EdgeDetect04Slavecount

Continuously counts the detected slave edges. The contents of this register are only updated on a master edge. This counter can detect if several slave edges occur before a master edge.

| Data type | Values | Information |
|-----------|-----------------|---|
| SINT | -128 to 127 | Number of detected slave edges (8-bit) |
| INT | -32768 to 32767 | Number of detected slave edges (16-bit) |

9.16.5.11.10.9 Difference between master and slave edge

Name:

EdgeDetect01Difference to EdgeDetect04Difference

This register contains the time difference between a master edge and the last slave edge addressed by "[Slave leading](#)" on page 1983.

| Data type | Values | Information |
|-----------|---------------------------------|---|
| INT | -32768 to 32767 | Slave edge / Master edge time difference (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Slave edge / Master edge time difference (32-bit) |

9.16.5.11.10.10 NetTime when a master edge occurs

Name:

EdgeDetect01Mastertime to EdgeDetect04Mastertime

The exact NetTime is copied to this register when a master edge occurs.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values | Information |
|-----------|---------------------------------|--|
| INT | -32768 to 32767 | NetTime master edge in microseconds (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime master edge in microseconds (32-bit) |

9.16.5.11.10.11 NetTime when a slave edge occurs

Name:

EdgeDetect01Slavetime to EdgeDetect04Slavetime

When a master edge occurs, the exact NetTime of any slave edge that may have occurred prior to the master edge and addressed by "[Slave leading](#)" on page 1983 is copied to this register. If multiple slave edges occur before a master edge, then only the NetTime of the last edge that was not ignored by "[Slave leading](#)" is stored. The occurrence of multiple edges can be determined by register "[EdgeDetectSlavecount](#)" on page 1983.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values | Information |
|-----------|---------------------------------|---|
| INT | -32768 to 32767 | NetTime slave edge in microseconds (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime slave edge in microseconds (32-bit) |

9.16.5.11.11 Motion functions

Encoder emulation can be used to generate up/down counters (direction/frequency) and ABR encoder signals. The following conditions must be met to achieve an exact match of the position of the module with the remote station:

- Up/Down counter: The remote station must evaluate both rising and falling edges.
- ABR encoder: The remote station must employ 4x evaluation.

The motion function can be operated in 2 different operating modes:

- "Mode "Position control"" on page 1985
- "Mode "Speed control"" on page 1986

Minimizing jitter

Depending on the configuration of the module, unfavorable system-related jitter times can result in every motion function. In order to increase the smooth running of the motor, however, the flank switching times and thus the unfavorable jitter can be minimized using register "CfO_ResolPosition" on page 1990.

9.16.5.11.11.1 Mode "Position control"

Each time register "MovTargetTime" on page 1992 changes, a new position setpoint is transferred from register "MovPosition" on page 1992 to the FIFO buffer. The time/position data in the FIFO buffer is then processed in such a manner that the positions are always reached at the moment of the respective timestamps. This means that the module internally ensures that the positions are reached by the set timestamps (number/frequency of the pulses is calculated automatically). The timestamps can be based on the X2X NetTime, the system time of the CPU or register "MovCurrentTime" on page 1992. Timestamps that are set in a manner that does not allow the required position change to be reached before the timestamp (output frequency of the pulse would exceed "CfO_SpeedLimit" on page 1988) cause a *MovMaxFrequencyViolation* error.

For more information about NetTime and timestamps, see "NetTime Technology" on page 3035.

Selected values for the example "Timing of movement":

| | |
|--|-------------------------------|
| Timestamp A = $\text{MovTimeValid} + 40,000$ | Position for timestamp A = 0 |
| Timestamp B = $\text{Timestamp A} + 40,000$ | Position for timestamp B = 10 |
| Timestamp C = $\text{Timestamp B} + 25,000$ | Position for timestamp C = 10 |
| Timestamp D = $\text{Timestamp C} + 70,000$ | Position for timestamp D = 20 |
| Timestamp E = $\text{Timestamp D} + 15,000$ | Position for timestamp E = 20 |
| Timestamp F = $\text{Timestamp E} + 40,000$ | Position for timestamp F = 0 |

Configuration: Reference pulse 1 = Start position and margin, Start position = 0, Margin = 1

Configuration: Reference pulse 2 = Starting and end position, Starting position = 15, End position = 17

9.16.5.11.11.2 Mode "Speed control"

In mode "Speed control", the application only specifies the speed setpoint. The module returns the current position in register "MovPosition (32-bit)" on page 1992.

The default setting (resolSpeed = 24) is designed in such a way that a value of 16,777,216 (0x01000000) in register "MovSpeed" on page 1992 results in exactly one increment per "control period".

First, an internal speed value must be calculated:

$$vIntern = vOut * 2^{resolPos}$$

This results in the following correlation for a 32-bit speed specification (data format of the speed values = 32-bit):

$$MovSpeed = vIntern * 2^{resolSpeed} * period$$

Atypically to other registers, when writing to register "MovSpeed (16-bit)", the 2 higher-order bytes of "MovSpeed (32-bit)" are written. This results in the following correlation for direct calculation with "MovSpeed (16-bit)".

$$MovSpeed = \frac{vIntern * 2^{resolSpeed} * period}{2^{16}}$$

| Variable | Description | Unit |
|---|---|-------|
| MovSpeed | Value for register "MovSpeed" (16- or 32-bit) | |
| vIntern | Internally calculated speed value. | Inc/s |
| vOut | Desired output speed. Each edge (rising or falling) counts as an increment. | Inc/s |
| resolPos | Configured value of register "CfO_ResolPosition" on page 1990 | |
| resolSpeed | Configured value of register "CfO_ResolSpeed" on page 1990 | Bits |
| period | Configured value of register "CfO_SpeedCycleTime_32Bit" on page 1989 | s |
| <p>Information:</p> <p>Must be set in microseconds in Automation Studio. The calculation is performed in s, however.</p> | | |

9.16.5.11.11.3 Performing a movement in mode "Position control"

Several things must be kept in mind when operating the module in order to perform a movement without errors and avoid error messages.

Information:

The specified time/position pairs are not "movement commands", but position data that is continuously processed by the module.

- To allow the module to calculate movement pulses, the first time/position data pair (t, x) is interpreted as the home position. In this case, "t" represents the starting moment and "x" the current position. A movement is not yet performed.
- As long as bit 0 "MovEnable - For position control" on page 1991 is set to "1", time/position data pairs must be continuously transmitted to the module. As soon as the last data pair has been processed and the module does not find another data pair in the FIFO buffer, error message MovFifoEmpty is sent (see "Error state - Motion functions" on page 1969). In addition, error message MovTargetTimeViolation occurs because no "future moment" for another movement was found.
- To enable a standstill, the time/position data pairs must be specified with an unchanged position but future moments in time.
- Ending the movement with bit 0 = "0" "MovEnable - For position control" on page 1991
This only stops filling the FIFO buffer and subsequently suppresses error message MovFifoEmpty. All entries in the FIFO buffer are still processed. The last specified position is applied as the reference position. As soon as bit 0 = "1" again, all movements are performed relative to this position.
- Ending the movement with bit 7 = "1" "MovReset - Movement reset (immediate stop)" on page 1991
This stops the movement immediately. No more pulses are output. To restart the movement, bit 7 must be set to "0" and bit 0 must be set to "0" for a short time and then back to "1".

9.16.5.11.11.4 FIFO buffer size

Name:

FifoSize

"Number of FIFO buffer entries" in the Automation Studio I/O configuration.

Determines the size of the FIFO buffer for "MovTargetTime" on page 1992 and "MovTargetPosition" on page 1992. One timestamp and one position that should be reached by the timestamp can be transferred to the FIFO buffer per X2X cycle.

| Data type | Values | Information |
|-----------|--------|-------------------------------|
| USINT | 0 | FIFO buffer disabled |
| | 3 | 8 entries (2 ³) |
| | 4 | 16 entries (2 ⁴) |
| | 5 | 32 entries (2 ⁵) |
| | 6 | 64 entries (2 ⁶) |
| | 7 | 128 entries (2 ⁷) |
| | 8 | 256 entries (2 ⁸) |

9.16.5.11.11.5 Motion function mode

Name:

CfO_Mode

The mode of the motion functions can be configured in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---|-------|---|
| 0 | Must be enabled when working without timestamps. Enabled in Automation Studio if: <ul style="list-style-type: none"> "Movement = Speed control" "Movement = Position control" and "Data format / Mode of the preset time value = Local time" | 0 | Disabled |
| | | 1 | Enabled |
| 1 | If this function is enabled, repositioning is triggered as soon as the value in register "MovPosition" on page 1992 changes. Enabled in Automation Studio if: <ul style="list-style-type: none"> "Movement = Position control" and "Data format / Mode of the preset time value = Local time" | 0 | No position control (speed control) |
| | | 1 | Position control enabled (position control) |
| 2 | Reference mode 1 "Configuration of reference pulse #1" in the Automation Studio I/O configuration. | 0 | Starting/Limit position |
| | | 1 | Starting position and span |
| 3 | Reference mode 2 "Configuration of reference pulse #1" in the Automation Studio I/O configuration. | 0 | Starting/End position |
| | | 1 | Starting position and span |
| 4 - 7 | Reserved | - | |

9.16.5.11.11.6 Maximum output frequency

Name:

CfO_SpeedLimit

"Max. movement frequency" in the Automation Studio I/O configuration.

Configures the maximum permissible output frequency and the maximum internal computing frequency. The higher internal computing frequencies of 500 kHz or 1, 2, 4, 8, 16, 32 and 64 MHz can only be achieved by configuring n bits as decimal places (see register "[CfO_ResolPosition](#)" on page 1990).

| Data type | Values | Max. increment frequency | Max. frequency for frequency output channel | Max. frequency for A/B output channel |
|-----------|---------|--------------------------|---|---------------------------------------|
| USINT | 253 | 64 MHz | 125 kHz | 62.5 kHz |
| | 254 | 32 MHz | | |
| | 255 | 16 MHz | | |
| | 0 | 8 MHz | | |
| | 1 | 4 MHz | | |
| | 2 | 2 MHz | | |
| | 3 | 1 MHz | | |
| | 4 | 500 kHz | | |
| | 5 | 250 kHz (default) | 62.5 kHz | 31.25 kHz |
| 6 | 125 kHz | | | |

Information:

In movement "Position control", increment frequencies 16, 32 and 64 MHz are not permitted to be used when 29-bit timestamps are set (see register "[CfO_TimeStampRange](#)" on page 1988) due to an internal range overrun.

9.16.5.11.11.7 Number of absolute bits that can be output

Name:

CfO_FormatAdjust

The number of bits that can be output absolutely on the signal output are determined in this register (e.g. for a direction/frequency signal, the least significant bit can be output directly on the frequency output; for an AB signal, 2 bits are possible).

| Data type | Values | Information |
|-----------|--------|--|
| USINT | 1 to 2 | Number of absolute bits (default value in Automation Studio = 1) |

9.16.5.11.11.8 Width of the transferred timestamp data

Name:

CfO_TimeStampRange

"Data format / Mode of the preset time value" in the Automation Studio I/O configuration.

The width of the transferred [timestamp data](#) in the module is configured in this register.

Information:

Since the module works internally with 1/8 µs resolution, timestamp data is processed internally with a maximum width of 29 bits.

| Data type | Values | Information |
|-----------|--------|--|
| SINT | 16 | 16-bit timestamp (selection "16-bit" in the Automation Studio I/O configuration) |
| | 24 | 24-bit timestamp (selection "Local time" or movement "Speed control" in the Automation Studio I/O configuration) |
| | 29 | 29-bit timestamp (selection "29-bit" in the Automation Studio I/O configuration) |

9.16.5.11.11.9 Number of bits for position control

Name:

CfO_PositionsRange

"Target position range" in the Automation Studio I/O configuration.

The number of bits for position control are configured in this register. "PositionRange" must be reduced if the motion function should follow the absolute value of a 12-bit SSI encoder, for example. In this case, the bit width of the movement position must also be limited to the number of bits of the encoder; otherwise, the movement position would not be overrun if the encoder overflows. In this case, the module would attempt (in the opposite direction) to reach the position of an encoder that had just overflow.

Example

The 12-bit SSI encoder overflows from 2047 to -2048. The module would generate 4096 negative increments if more than 12 bits were set for "CfO_PositionRange" in order to reach position -2048 from the position 2047.

Information:

If the 16-bit value of register "MovPosition" on page 1992 is used, then the number of bits of the position must also be limited to ≤ 16 ; otherwise, this would also result in incorrect overflow behavior.

| Data type | Values | Information |
|-----------|---------|-------------------------------------|
| SINT | 8 to 32 | Number of bits for position control |

9.16.5.11.11.10 Number of bits for reference position comparison

Name:

CfO_Reference0Range to CfO_Reference1Range

"Reference #1 range" to "Reference #2 range" in the Automation Studio I/O configuration.

The number of bits used for the reference position comparison are configured in this register. This makes it possible to generate a reference pulse every 2^n increments.

Information:

The number of bits set in this register is not permitted to exceed the number of bits of data points "MovReferenceStart" on page 1991 and "MovReferenceStopMargin" on page 1991.

| Data type | Values | Information |
|-----------|---------|--|
| SINT | 4 to 32 | Number of bits for position comparison |

9.16.5.11.11.11 Timestamp delay

Name:

CfO_TimeStampDelay

"Default time delay" in the Automation Studio I/O configuration.

All [timestamps](#) are delayed by the value set in this register in microseconds.

Information:

When setting to "Local time" in register "CfO_TimeStampRange" on page 1988, a value at least 2x the X2X cycle time in microseconds must be entered here.

| Data type | Values | Information |
|-----------|--------------|---------------------------------|
| DINT | 0 to 1000000 | Timestamp delay in microseconds |

9.16.5.11.11.12 Control period for mode "Speed control"

Name:

CfO_SpeedCycleTime_32Bit

"Control period" in the Automation Studio I/O configuration.

The control period for mode "Speed control" can be configured in $1/8 \mu\text{s}$ steps in this register.

Information:

The value set in the Automation Studio I/O configuration under "Control period" is automatically multiplied by 8 and then used as CfO_SpeedCycleTime_32bit.

| Data type | Values | Information |
|-----------|--------------|---|
| UDINT | 400 to 40000 | Control period for mode "Speed control" |

9.16.5.11.11.13 Minimizing jitter for the position

Name:

CfO_ResolPosition

"Position resolution" in the Automation Studio I/O configuration.

This register contains the number of bits as decimal place for jitter reduction. Internally, the module adds 2^n (n = number of decimal places) to the frequency, which results in edge switching times with a higher resolution. The output switching frequency is not increased from a hardware perspective, but the edge moment is more precise.

| Data type | Values | Information |
|-----------|---------|-------------------------------------|
| SINT | 0 | Default, no decimal places |
| | 1 to 14 | Selection of bits as decimal places |

Information:

It is important to note that each configured decimal place also limits the maximum number range by that number of bits.

For example: 0 decimal places → Maximum position range = 29-bit

3 decimal places → Maximum position range = 26-bit

It is also important to note that register "[CfO_SpeedLimit](#)" on page 1988 must be adjusted for these higher computing frequencies according to the number of configured decimal places.

9.16.5.11.11.14 Minimizing jitter for the speed

Name:

CfO_ResolSpeed

"Speed resolution" in the Automation Studio I/O configuration.

This register contains the number of bits for minimizing the jitter of the speed value as decimal places. Within the module, a 2^n (n = number of decimal places) higher frequency is calculated, resulting in speed values with higher resolution.

A 16-bit or 32-bit speed value is basically configured in the Automation Studio I/O configuration due to the bit limitation. Since the internal calculation is always based on a 32-bit configuration, offset 16 must always be added to the desired decimal places for 16-bit configurations.

| Data type | Values | Information |
|-----------|---------|---|
| SINT | 0 to 31 | Selection of bits as decimal places. Default value in Automation Studio = 24 |

Information:

It is important to note that each configured decimal place also limits the maximum number range by that number of bits.

9.16.5.11.11.15 Acceleration value

Name:

CfO_AccelDataInt

MovAcceleration

"Acceleration value" in the Automation Studio I/O configuration.

The acceleration value in increments per [control period](#)² is contained in this register.

- 32-bit: 16777216 (0x01000000) corresponds to 1 increment per control period²
- 16-bit: 256 (0x0100) corresponds to 1 increment per control period²

| Data type | Values | Information |
|-----------|--------------------|-----------------------------|
| UINT | 0 to 65535 | Acceleration value (16-bit) |
| UDINT | 0 to 4,294,967,296 | Acceleration value (32-bit) |

9.16.5.11.11.16 Starting position of the reference pulses

Name:

CfO_Reference0Start to CfO_Reference1Start

MovReference1Start to MovReference2Start

"Starting position" in the Automation Studio I/O configuration

The starting position for the reference pulses is contained in these registers.

If the direction is positive, the output (R) is set when the starting position is reached. In the negative direction, the output is reset as soon as the starting position is undershot.

| Data type | Values | Information |
|-----------|---------------------------------|----------------------------|
| INT | -32768 to 32767 | Starting position (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Starting position (32-bit) |

9.16.5.11.11.17 End position or range of the reference pulse output

Name:

CfO_Reference0StopMargin to CfO_Reference1StopMargin

MovReference1StopMargin to MovReference2StopMargin

"End position or range" in the Automation Studio I/O configuration

The end position or range in which the reference pulse is output can be configured in these registers.

If setting "Reference mode x = Starting/End position" is used in register "CfO_Mode" on page 1987, the output (R) is reset when the end position is reached if the direction is positive. In the negative direction, the output is set as soon as the end position is undershot.

When using "Reference mode x = Starting position and span", the contents of this register are added to the starting position and the resulting sum is used as the end position.

| Data type | Values | Information |
|-----------|---------------------------------|-----------------------|
| INT | -32768 to 32767 | End position (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | End position (32-bit) |

9.16.5.11.11.18 Enabling position and speed control

Name:

MovEnable

MovEnable

MovReset

This register can be used to enable position and speed control.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|---------------------------|
| 0 | MovEnable - For position control | 0 | Position control disabled |
| | | 1 | Position control enabled |
| 1 | MovEnable - For speed control | 0 | Speed control disabled |
| | | 1 | Speed control enabled |
| 2 - 6 | Reserved | - | |
| 7 | MovReset - Movement reset (immediate stop) | 0 | No function |
| | | 1 | Reset active |

9.16.5.11.11.19 Timestamp data of the target position

Name:

MovTargetTime

The **timestamp data** is contained in this register. Each time this register changes, the new position data ("**MovTargetPosition**" on page 1992) and timestamp data are transferred to the FIFO buffer. If bit 1 for speed control "**MovEnable = True**", the module calculates the output speed (frequency) so that "**MovTargetPosition**" is reached based on "**MovTargetTime**".

| Data type | Values | Information |
|-----------|------------------------------------|------------------------------------|
| INT | -32768 to 32767 | Timestamp in microseconds (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Timestamp in microseconds (32-bit) |

Information:

Only 29 bits are processed internally by this register.

9.16.5.11.11.20 Data of the target position

Name:

MovTargetPosition

The position data is contained in this register.

| Data type | Values | Information |
|-----------|------------------------------------|-------------------|
| INT | -32768 to 32767 | Position (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Position (32-bit) |

9.16.5.11.11.21 Velocity setpoint

Name:

MovSpeed

The speed setpoint for mode "Speed control" in increments per **control period** is contained in this register.

- 32-bit: 16,777,216 (0x01000000) corresponds to 1 increment per control period
- 16-bit: 256 (0x0100) corresponds to 1 increment per control period

| Data type | Values | Information |
|-----------|------------------------------------|-------------------------|
| INT | -32768 to 32767 | Speed setpoint (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Speed setpoint (32-bit) |

9.16.5.11.11.22 NetTime of the current position

Name:

MovTimeValid

The NetTime of the current position is contained in this register.

For more information about NetTime and timestamps, see "**NetTime Technology**" on page 3035.

| Data type | Values | Information |
|-----------|------------------------------------|--|
| INT | -32768 to 32767 | NetTime of the current position in microseconds (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime of the current position in microseconds (32-bit) |

9.16.5.11.11.23 Current position

Name:

MovPosition

The current position is contained in this register.

| Data type | Values | Information |
|-----------|------------------------------------|---------------------------|
| INT | -32768 to 32767 | Current position (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Current position (32-bit) |

9.16.5.11.12 Synchronous Serial Interface (SSI)

Synchronous Serial Interface makes it possible to receive data from SSI absolute encoders.

2 cables are required for data exchange:

SSI clock: Generated by the module on output 7 (if configured)
 SSI data: With each clock pulse, one data bit is transferred from the encoder to the module (input 5 can be used as the SSI input).

9.16.5.11.12.1 Procedure for SSI transfer

On the first edge on the SSI clock, a monostable multivibrator is triggered in the encoder and the value currently present in parallel is latched to the shift register (the low level of the monostable multivibrator prevents the transfer of additional values to the shift register during data transfer).

On the next edge, the most significant bit is transferred to the module.

With each additional clock pulse, the next least significant bit is transferred. The clocks constantly retrigger the monostable multivibrator, which prevents its output from accepting new data.

If the number of data bits set in register "[CfO_DataBits](#)" on page 1994 have been received, the clock sequence is ended.

The monostable multivibrator is no longer triggered; after a time dependent on the encoder, the output of the monostable multivibrator accepts the output level again, thus allowing parallel data to be transferred to the encoder's shift register.

With monostable multivibrator testing, the data line is queried for the configured level before starting a new transfer. This makes it possible to ensure that the monostable multivibrator has really returned before a new transfer is started.

Transferring using Synchronous Serial Interface

Processing the measured value

- 1) Start bit ... The measured value is saved.
- 2) Output of the first data bit
- 3) All data bits are transferred; the monostable multivibrator time starts to run.
- 4) The monostable multivibrator returns to its initial state; a new transfer can be started.

9.16.5.11.12.2 Update cycle - Starting SSI transfer

Name:

CfO_CycleSelect

"Update cycle" in the Automation Studio I/O configuration.

SSI transfer is started at the update cycle. The clock sequence is generated on the SSI clock output. The first edge of the clock signal triggers the monoflop in the encoder and latches the current position. At the same time, the current [NetTime](#) is also logged in register "[SSITimeValid](#)" on page 1994. As soon as all bits have been transferred via the SSI, the position is passed on with the next "SIframeGenCycle" via the X2X Link. A [SSICycleTimeViolation](#) error is reported if the SSI transfer is not completed within the SSI update cycle (e.g. system timer as update cycle). The SSI transfer is still fully completed and then started again with the next update cycle.

| Data type | Values | Information |
|-----------|--------|------------------------|
| USINT | 2 | System timer |
| | 3 | Prescaled system timer |
| | 10 | AOAI |
| | 14 | SOSI |

9.16.5.11.12.3 Configuring the SSI interface

Name:

CfO_PhysicalMode

"Parity bit" in the Automation Studio I/O configuration

"Monostable multivibrator testing" in the Automation Studio I/O configuration

"Data format" in the Automation Studio I/O configuration

"Clock frequency" in the Automation Studio I/O configuration

The SSI interface is configured in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---|----------|--|
| 0 - 1 | "Parity bit" ⁽¹⁾ | 00 | Disabled |
| | | 01 | Even parity |
| | | 10 | Odd parity |
| | | 11 | Ignore (the parity bit is transferred but not evaluated) |
| 2 - 3 | "Monostable multivibrator testing" ⁽²⁾ | 00 | Disabled |
| | | 01 | Low level (the data signal is checked for a low level after the monostable multivibrator has returned to its stable state) |
| | | 10 | High level (data signal is checked for high level after the monostable multivibrator has returned to its stable state) |
| | | 11 | Ignore (the necessary clock is triggered but not evaluated) |
| 4 | "Data format" | 0 | Encoder with binary data output |
| | | 1 | Encoder with Gray code. The position data is converted into binary format by the module. |
| 5 | Reserved | - | |
| 6 - 7 | "Clock frequency" | 00 to 10 | Not permitted |
| | | 11 | 125 kHz |

- 1) If the parity bit is not correct, [SSIParityError](#) is generated and the position data is not applied to register ["SSIPosition"](#) on page 1995.
- 2) As long as the data signal has not reached the level defined for monostable multivibrator testing after the transfer, no new SSI transfer is started. This will trigger error [SSICycleTimeViolation](#).

9.16.5.11.12.4 Valid number of SSI data bits

Name:

CfO_DataBits

"Valid number of SSI data bits" in the Automation Studio I/O configuration.

Determines the number of valid data bits to be transferred via SSI. The valid data bits are used for ["SSIPosition"](#) on page 1995.

| Data type | Values | Information |
|-----------|---------|---------------------------|
| USINT | 1 to 32 | Number of valid data bits |

9.16.5.11.12.5 Number of leading zero bits

Name:

CfO_NullBits

"Number of leading zero bits" in the Automation Studio I/O configuration.

The number of leading zero bits can be configured in this register. The leading zero bits may be required before the valid data bits.

| Data type | Values | Information |
|-----------|---------|-----------------------------|
| USINT | 0 to 31 | Number of leading zero bits |

9.16.5.11.12.6 NetTime of the current position

Name:

SSITimeValid

The NetTime of the current position is contained in this register.

For more information about NetTime and timestamps, see ["NetTime Technology"](#) on page 3035.

| Data type | Values | Information |
|-----------|---------------------------------|--|
| INT | -32768 to 32767 | NetTime of the current position in microseconds (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime of the current position in microseconds (32-bit) |

9.16.5.11.12.7 NetTime of the last position change

Name:

SSITimeChanged

The NetTime at which the last position change took place is contained in this register.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values | Information |
|-----------|---------------------------------|--|
| INT | -32768 to 32767 | NetTime of the last position change in microseconds (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime of the last position change in microseconds (32-bit) |

9.16.5.11.12.8 Current position

Name:

SSIPosition

The current position transferred via the SSI interface is contained in this register.

| Data type | Values | Information |
|-----------|---------------------------------|---------------------------|
| INT | -32768 to 32767 | Current position (16-bit) |
| UDINT | 0 to 4,294,967,295 | Current position (32-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | |

9.16.5.11.13 Counter

The universal counter pair can be used in 3 different modes. Signals up to 100 kHz are reliably detected. Up to 4 latch inputs can be configured in all modes. If required, the enabled latch inputs are negated and linked to a latch condition with a logical AND operator. If the latch condition is met, the current counter value is saved to a separate register.

Inputs

Depending on the function model, the physical inputs are permanently configured for the counter.

| Mode | Input 1 | Input 2 | Input 5 | Input 6 |
|----------------------|--|--|--------------------|--------------------|
| Edge counter | Counter input for counter 1 Latch input 1 | Counter input for counter 2 Latch input 2 | - Latch input 3 | - Latch input 4 |
| Up/Down counter | Counting direction Latch input 1 | Counter frequency Latch input 2 | - Latch input 3 | - Latch input 4 |
| Incremental encoders | A Latch input 1 | B Latch input 2 | - Latch input 3 | - Latch input 4 |

Latch function

As latch inputs, inputs 1, 2, 5 and 6 can each be queried for a high or low level.

With "Latch mode = Continuous", the counters are latched once as soon as "[LatchEnable](#) = True" and the configured latch condition is met. When the latch condition is met again, the counter content is latched again (i.e. a latch event is triggered on every rising edge of the output of the AND operator of all latch inputs).

With "Latch mode = Single", the counters are latched once as soon as "[LatchEnable](#) = True" and the configured latch condition is met. When the latch condition is met again, the counter content is not automatically recopied. Another latch event can only be processed after "[LatchEnable](#) = False" and another "[LatchEnable](#) = True".

9.16.5.11.13.1 Update cycle for counter values

Name:

CfO_CounterCycleSelect

"Update cycle" in the Automation Studio I/O configuration.

The update cycle for the counter values is configured in this register.

Information:

The maximum counting frequency depends on this cycle. The module can process a maximum of 200 increments (edges) within one counter cycle.

| Data type | Values | Information |
|-----------|--------|----------------------------|
| USINT | 2 | System timer |
| | 3 | Prescaled system timer |
| | 10 | AOAI moment from X2X cycle |
| | 14 | SOSI moment from X2X cycle |

9.16.5.11.13.2 Counter mode

Name:

CfO_CounterMode

"Counter mode" in the Automation Studio I/O configuration.

The counter mode is configured in this register.

| Data type | Values | Information |
|-----------|--------|---|
| USINT | 0 | Edge counter The two counters serve as edge counters in this mode. The counter input of counter 1 is permanently connected to input 1; the counter input of the second counter is permanently connected to input 2. Both rising and falling edges are counted. |
| | 2 | Up/Down counter The up/down counter works according to the direction/frequency principle. Input 1 sets the counting direction (LOW = positive, HIGH = negative); input 2 is used as the counter frequency input. Both rising and falling edges on the counter frequency input are counted. |
| | 3 | Incremental encoder (AB counter) When configured as an AB counter, input 1 is used as the A channel and input 2 is used as the B channel. All edges are evaluated (4x evaluation). |

9.16.5.11.13.3 Latch mode

Name:

CfO_LatchMode

"Latch mode" in the Automation Studio I/O configuration.

The latch mode is configured in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-------------|
| 0 | LatchMode | 0 | One-time |
| | | 1 | Continuous |
| 1 - 7 | Reserved | - | |

9.16.5.11.13.4 Latch comparators for counter inputs

Name:

CfO_LatchComparator

"Latch level of channel 0x" in the Automation Studio I/O configuration.

The latch comparators for the counter inputs are configured in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|--|-------|-------------|
| 0 | Comparison level for the latch comparator on input 1 | 0 | LOW |
| | | 1 | HIGH |
| 1 | Comparison level for the latch comparator on input 2 | 0 | LOW |
| | | 1 | HIGH |
| 2 | Comparison level for the latch comparator on input 5 | 0 | LOW |
| | | 1 | HIGH |
| 3 | Comparison level for the latch comparator on input 6 | 0 | LOW |
| | | 1 | HIGH |
| 4 | Enables the latch comparator on input 1 | 0 | Disabled |
| | | 1 | Enabled |
| 5 | Enables the latch comparator on input 2 | 0 | Disabled |
| | | 1 | Enabled |
| 6 | Enables the latch comparator on input 5 | 0 | Disabled |
| | | 1 | Enabled |
| 7 | Enables the latch comparator on input 6 | 0 | Disabled |
| | | 1 | Enabled |

9.16.5.11.13.5 Clearing counter values and enabling latching

Name:

CounterReset

LatchEnable

Counter values can be deleted or the latch enabled using this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|----------------|
| 0 | CounterReset | 0 | No action |
| | | 1 | Delete counter |
| 1 | LatchEnable | 0 | Disabled |
| | | 1 | Enabled |
| 2 - 7 | Reserved | - | |

9.16.5.11.13.6 Counter for latch events

Name:

LatchCount

Latch events that occur are counted in this register. This counter can be used to detect whether a new value has been latched, for example.

| Data type | Values | Information |
|-----------|-------------|---------------|
| SINT | -128 to 127 | Latch counter |

9.16.5.11.13.7 NetTime of the current counter value

Name:

CounterTimeValid

The X2X NetTime of the current counter value is contained in this register.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Values | Information |
|-----------|---------------------------------|---|
| INT | -32768 to 32767 | NetTime of the current counter value in microseconds (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime of the current counter value in microseconds (32-bit) |

9.16.5.11.13.8 NetTime of the last counter value change

Name:

Counter01TimeChanged to Counter02TimeChanged

The NetTime at which the last change of the respective counter took place is contained in this register.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Values | Information |
|-----------|---------------------------------|---|
| INT | -32768 to 32767 | NetTime of the last change of the respective counter in microseconds (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime of the last change of the respective counter in microseconds (32-bit) |

9.16.5.11.13.9 Current counter value

Name:

CounterValue01 to CounterValue02

The current counter value of the respective counter is contained in this register.

| Data type | Values | Information |
|-----------|---------------------------------|--|
| INT | -32768 to 32767 | Counter value of the respective counter (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Counter value of the respective counter (32-bit) |

9.16.5.11.13.10 Latch counter

Name:

CounterLatch01 to CounterLatch02

As soon as the latch conditions set in register "[CfO_LatchComparator](#)" on page 1996 are met, the content of the relevant "[CounterValue register](#)" on page 1997 is copied to this register.

| Data type | Values | Information |
|-----------|------------------------------------|------------------------|
| INT | -32768 to 32767 | Latch counter (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Latch counter (32-bit) |

9.16.5.11.13.11 Counter value relative to the last latch

Name:

CounterRel01 to CounterRel02

In this register, the counter value of the respective counter is calculated relative to the last latch of the respective counter.

| Data type | Values | Information |
|-----------|------------------------------------|---|
| INT | -32768 to 32767 | Counter value relative to the last latch (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Counter value relative to the last latch (32-bit) |

9.16.5.11.14 NetTime Technology

For a description of NetTime Technology, see "[NetTime Technology](#)" on page 3035.

9.16.5.11.15 Minimum X2X cycle time

The minimum X2X cycle time is strongly dependent on the configured functions and the resulting load on the module. Setting "Fast reaction" and a very short system cycle (<50 μ s) generally have a negative effect on the minimum X2X cycle time. This can result in error behavior with short X2X cycle times.

9.16.6 X20DS1828

Data sheet version: 1.20

9.16.6.1 General information

The module is equipped with 1 HIPERFACE encoder interface. This module can be used to evaluate encoders installed in motors from other manufacturers as well as encoders for external axes (encoders that sample any machine movement). The input signals are monitored. This makes it possible to detect open or shorted lines as well as encoder supply failures.

- HIPERFACE encoder interface
- Encoder input monitoring
- 11 VDC and GND for encoder supply
- NetTime timestamp: Position time

HIPERFACE

HIPERFACE is a standard developed by Max Stegmann GmbH (www.stegmann.de), which like EnDat incorporates the advantages of absolute and incremental position measurement while also offering a read/write parameter memory in the encoder. With absolute position measurement (the absolute position is sampled serially), a homing procedure for referencing is usually not required. Where necessary, a multi-turn encoder should be installed. To reduce costs, a single-turn encoder and a reference switch can also be used. In this case, a homing procedure must be carried out.

The incremental process allows the short deceleration periods necessary for position measurement when using drives with highly dynamic characteristics. With the sinusoidal incremental signal and the fine resolution in the HIPERFACE module, a very high positioning resolution is achieved in spite of the moderate signal frequencies used.

NetTime timestamp for the position

It is not just the position value that is important for highly dynamic positioning tasks, but also the exact time the position is measured. The module is equipped with a NetTime function for this that supplies a timestamp for the recorded position with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.16.6.2 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | Digital signal processing and preparation |  |
| X20DS1828 | X20 digital signal module, 1 HIPERFACE interface, NetTime function | |

9.16.6.4 LED status indicators

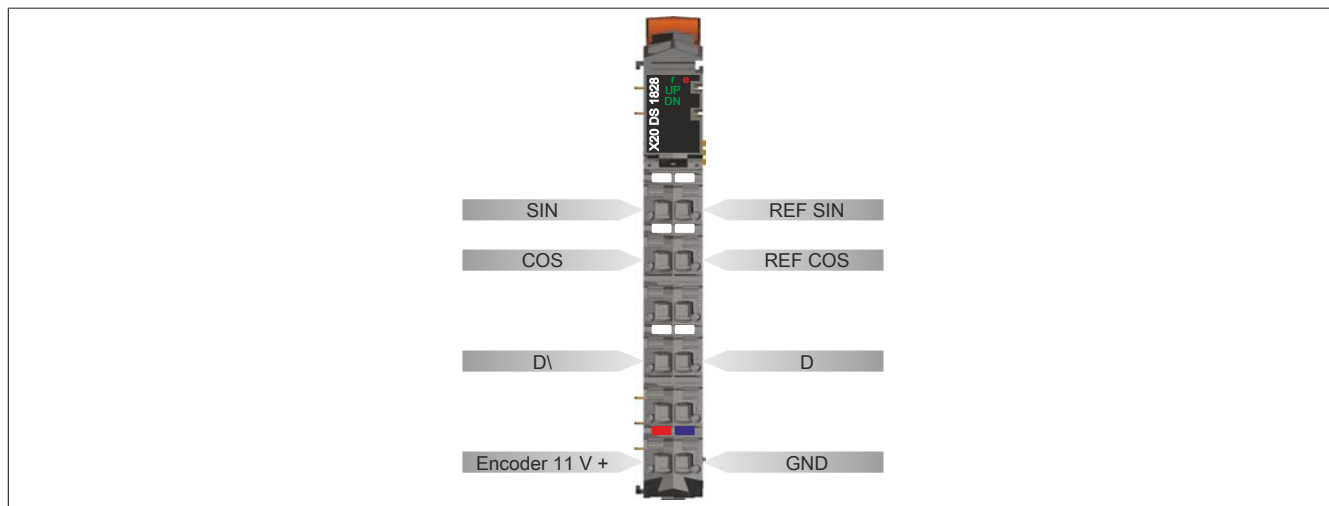

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|------------------------|--|---|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset state. Possible cause: <ul style="list-style-type: none"> Encoder supply error |
| | | | Single flash | I/O error - Possible causes: <ul style="list-style-type: none"> Sine/Cosine relative position error (open line) Sine/Cosine absolute position error (reference) |
| | | | Double flash | System error. Possible causes: <ul style="list-style-type: none"> HIPERFACE communication error |
| | | | Triple flash | I/O error and system error |
| | | | Single flash, inverted | Error or reset state and I/O error |
| | | | Double flash, inverted | Error or reset state and system error |
| | Triple flash, inverted | Error or reset state, I/O error and system error | | |
| | UP | Green | On | The "UP/DN" LEDs are lit depending on the rotational direction and the speed of the connected encoder. The "UP" LED indicates when the encoder position changes in the positive direction. |
| DN | Green | On | The "DN" LED indicates when the encoder position changes in the negative direction. | |

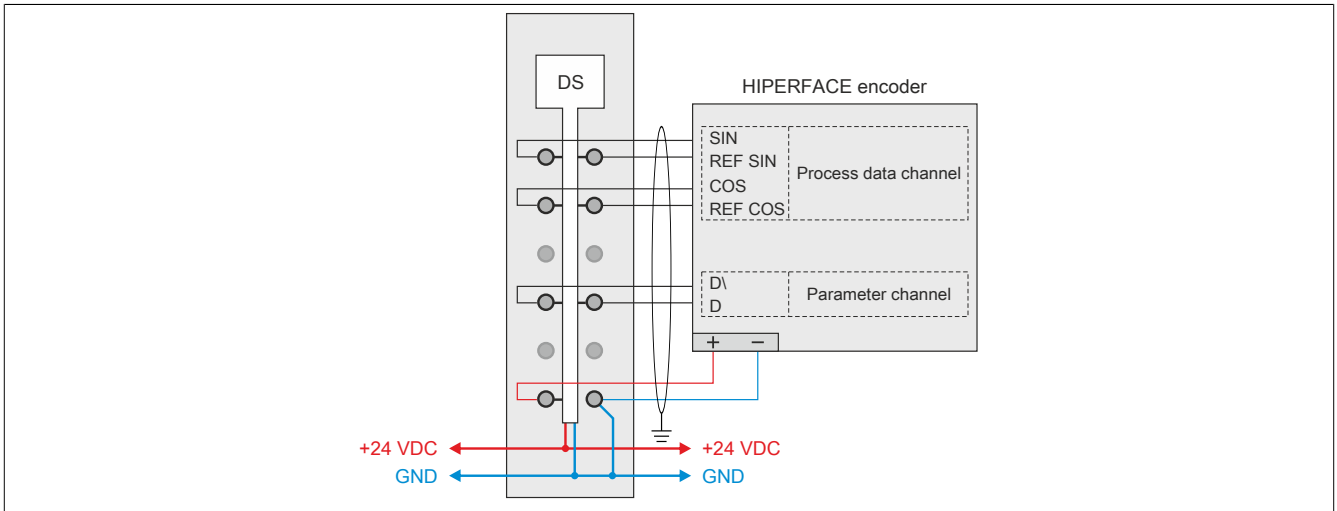

1) Depending on the configuration, a firmware update can take up to several minutes.

9.16.6.5 Pinout

Shielded cables must be used for all signal lines.

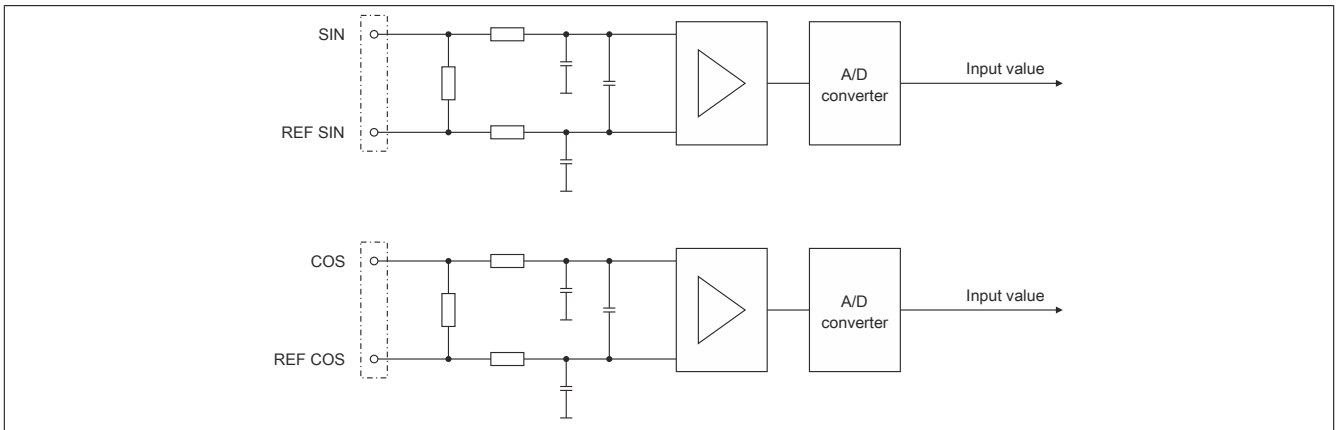

9.16.6.6 Connection example

9.16.6.7 Input circuit diagram

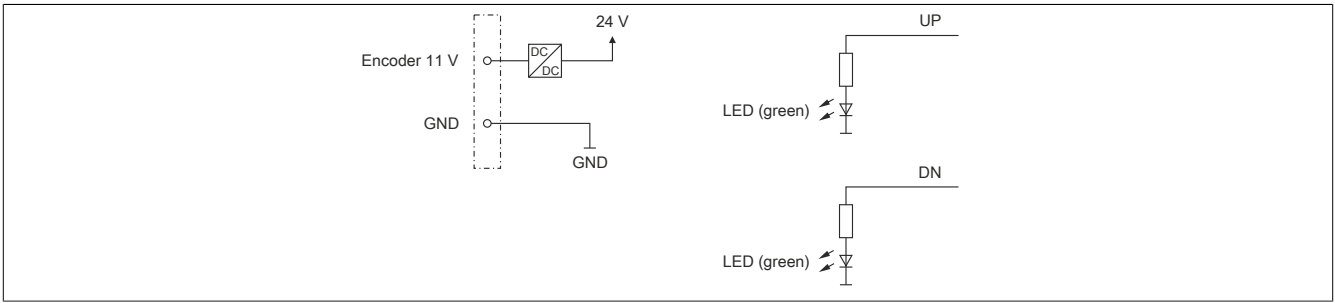

9.16.6.7.1 Diagram for the process data channel (sine-cosine track)

9.16.6.7.2 Circuit diagram for the parameter channel (RS485 interface)

9.16.6.7.3 Circuit diagram for the encoder supply and LEDs

9.16.6.8 Derating

There is no derating when operated below 55°C.

During operation over 55°C, the power dissipation of the modules to the left and right of this module is not permitted to exceed 1.15 W!

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

| | | | | | | |

|--|--|--|-------------|--|--|--|

9.16.6.9 Register description

9.16.6.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

1) The offset specifies the position of the register within the CAN object.

9.16.6.9.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.16.6.9.3.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.16.6.9.4 Module configuration

The following configuration register can be used to configure different module settings. They can be used, for example, to modify the module's behavior on an X2X Link network.

9.16.6.9.4.1 Data query

Name:

CfO_SlframeGenID

This register can be used to define when the synchronous/cyclic input data is generated. "X2X cycle optimized" should be set for jitter-free data acquisition. "Fast reaction" can be set for the best performance.

| Data type | Value | Information |
|-----------|-------|--|
| USINT | 9 | Fast reaction |
| | 14 | X2X cycle optimized; Bus controller default |

9.16.6.9.5 Basic functions

This module can import a position when used together with a HIPERFACE encoder. The received position data is prepared in 2 different formats and given a [timestamp](#). 6 registers are available for further processing. This allows the user to choose which format is best suited for individual application.

9.16.6.9.5.1 SDC counter register

Name:

SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

9.16.6.9.5.2 Absolute position values

Name:

PositionHW

PositionLW

The absolute position of the encoder is defined using 64-bit resolution. The position value is stored in the PositionHW and PositionLW registers. The upper 32 bits are stored the PositionHW register, while the lower 32 bits are stored in the PositionLW register.

For SinCos signal evaluation, see ["Format of the SinCos signal" on page 2012](#) for information regarding the data format.

| Data type | Value |
|-----------|--------------------|
| 2x UDINT | 0 to 4,294,967,295 |

9.16.6.9.5.3 SDC position value

Name:

Position

The SDC library requires a signed 32-bit position value. The position's low word can be accessed separately for this. The value can also be used as default position value, however.

For SinCos signal evaluation, see ["Format of the SinCos signal" on page 2012](#) for information regarding the data format.

| Data type | Value |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

9.16.6.9.5.4 NetTime of the position values

Name:

PosTime

The current NetTime value is assigned to each determined position in this register. The NetTime is recorded with μs accuracy.

The SDC library requires a 16 bit value. The NetTime value is therefore also prepared in this format.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Value | Information |
|-----------|------------------------------------|--------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime in μs |
| INT | -32,768 to 32,767 | |

9.16.6.9.5.5 Counter for position values

Name:

PosCycle

PosCycle is an integer counter that is incremented as soon as the module has saved a new valid position value.

| Data type | Value |
|-----------|-------------|
| SINT | -128 to 127 |

9.16.6.9.6 Error management

This module can be used to diagnose error states. There are 2 ways this module performs error diagnostics:

- ["Module-based diagnostics" on page 2009](#)
- ["HIPERFACE-based diagnostics" on page 2011](#)

9.16.6.9.6.1 Module-based diagnostics

Like most B&R modules, this module is also able to detect errors on its own. It diagnoses 5 different errors or warnings. The error bits can be retrieved individually or grouped together.

Enabling/disabling error messages

Name:

ErrorEnableID_0F08

The implemented diagnostic algorithms can be enabled or disabled in this register.

| Data type | Value | Bus controller default |
|-----------|--------------------|------------------------|
| USINT | See bit structure. | 255 |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------------------|-------|--|
| 0 | Encoder supply | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 1 | Reserved | - | |
| 2 | Vss Sin/Cos | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 3 | Position error | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 4 | HIPERFACE communication | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 5 | HIPERFACE reference warning | 0 | Warning disabled |
| | | 1 | Warning enabled (bus controller default setting) |
| 6 - 7 | Reserved | - | |

Encoder supply

The encoder voltage supply is below the permitted limit.

Vss Sin/Cos

The voltage value for the Sin/Cos track violates the configured limit values.

→ See register ["SinCosVssMin" on page 2013](#) or ["SinCosVssMax" on page 2013](#)

Position error

The position value determined violates internal requirements.

HIPERFACE communication

Communication error on the HIPERFACE interface (RS485)

→ See register ["HfErrorCode" on page 2011](#)

HIPERFACE reference warning

The digital interface provides an absolute position value that can be used to accurately describe the axis position. The position value is homed to this absolute value at the beginning of a measurement. The analog interface can be used to incrementally sample changes that occur very rapidly. This enables the module to continue sampling the position value at a high resolution. Both the analog and the digital signal are sampled cyclically. If the value read incrementally deviates from the absolute value during operation, then the warning is generated and the position must be homed again.

Show error messages

Name:
 ErrorInfo
 EncoderSupplyError
 VssCheckError
 PositionError
 HfComError
 HfRefWarning

This register indicates any errors or warnings that have not yet been acknowledged. For the meaning of individual error messages, see register "[Enabling/disabling error messages](#)" on page 2009.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|--------------------|-------|--------------------------------|
| 0 | EncoderSupplyError | 0 | No error |
| | | 1 | Encoder supply error |
| 1 | Reserved | - | |
| 2 | VssCheckError | 0 | No error |
| | | 1 | Vss error on the Sin/Cos track |
| 3 | PositionError | 0 | No error |
| | | 1 | Position error |
| 4 | HfComError | 0 | No error |
| | | 1 | HIPERFACE communication error |
| 5 | HfRefWarning | 0 | No warning |
| | | 1 | HIPERFACE reference warning |
| 6 - 7 | Reserved | - | |

Acknowledge error messages

Name:
 AckErrorInfo
 AckEncoderSupplyError
 AckVssCheckError
 AckPositionError
 AckHfComError
 AckHfRefWarning

This register is used to acknowledge an error or warning message that occurred in the "[Show error messages](#)" on page 2010 register. For the meaning of individual error messages, see register "[Enabling/disabling error messages](#)" on page 2009.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-----------------------|-------|-------------------------|
| 0 | AckEncoderSupplyError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 1 | Reserved | - | |
| 2 | AckVssCheckError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 3 | AckPositionError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 4 | AckHfComError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 5 | AckHfRefWarning | 0 | No acknowledgment |
| | | 1 | Acknowledgment |
| 6 - 7 | Reserved | - | |

9.16.6.9.6.2 HIPERFACE-based diagnostics

Memory areas are provided in the HIPERFACE standard for error diagnostics. Error management has been adjusted in order to use error detection in accordance with the HIPERFACE standard. An additional register has been implemented in the module to provide this area in the encoder's memory. This error memory is mirrored in the module's registers and can be interpreted by the user. Detailed information regarding the errors that can be detected in this way can be found in the encoder's manual.

HfErrorCode

Name:

HfErrorCode

This register is used to store the error code that identifies the current problem with the HIPERFACE interface.

| Data type | Value |
|-----------|--------------------|
| UDINT | See bit structure. |

Internally, the register consists of 4 pieces of information.

Bit structure:

| Bit | Name | Information |
|---------|-----------------|--|
| 00 - 07 | Error ID | See below |
| 08 - 15 | Last command | Command that caused the error on the slave |
| 16 - 23 | Station address | Address of the faulty HIPERFACE slave |
| 24 - 31 | Error counter | Counts the number of errors that have occurred |

Bit 00-07 (error ID)

These 8 bits of this register specify the error that has occurred. The error ID is not a standard value, however, and must be looked up in the manual for the HIPERFACE slave. The module also diagnoses a timeout on the HIPERFACE interface. This triggers error ID 255.

9.16.6.9.7 Sin/Cos - Analog interface configuration

In addition to the digital HIPERFACE interface, this module is also equipped with an analog interface for sampling a differential sine-cosine signal. To increase the resolution, the EnDat standard supports cooperation between the analog and digital data. This enables a highly dynamic representation of the position while maintaining high resolution.

9.16.6.9.7.1 Format of the SinCos signal

The SinCos signal is represented as a position value in the "Absolute position values" on page 2007 and "SDC position value" on page 2008 registers. The following relationships apply:

- PositionLW and Position are identical in the function.
- PositionHW extends the integer range of PositionLW by adding multi-turn functionality.

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|------------------------|----------------------------------|---|---|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 64-bit register | PositionHW (unsigned) | | PositionLW (unsigned) | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 32-bit register | - | | Position (signed) | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Format | Integer extension (to 48-bit) | Integer (16-bit) | Decimal places: (with 13-bit resolution) | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Information | | A full sine wave corresponds to an increment of the integer. | <table border="1"> <tr> <td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td> </tr> <tr> <td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>0</td><td>0</td><td>0</td> </tr> </table> <p>Important: The lower 3 bits always contain the value 0.</p> | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | x | x | x | x | x | x | x | x | x | x | x | x | x | 0 | 0 | 0 |

Relationship between sine curve (red) and decimal places:

9.16.6.9.7.2 Enabling SinCos

Name:
SinCosEnable

This register must always have the value 1 for configuration reasons.

| Data type | Value | Information |
|-----------|-------|---------------------------|
| USINT | 1 | Bus controller default: 1 |

9.16.6.9.7.3 SinCosRefSource

Name:
SinCosRefSource

This register must always have the value 3 for configuration reasons.

| Data type | Value | Information |
|-----------|-------|---------------------------|
| USINT | 3 | Bus controller default: 3 |

9.16.6.9.7.4 Configuring the lower Vss value

Name:

SinCosVssMin

This register specifies the lower limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value falls below this specified limit, then the module reports the corresponding error.

| Data type | Value | Information |
|-----------|-----------|---|
| UINT | 0 to 1500 | Values in mV Bus controller default: 800 |

9.16.6.9.7.5 Configuring the upper Vss value

Name:

SinCosVssMax

This register specifies the upper limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value exceeds this specified limit, then the module reports the corresponding error.

| Data type | Value | Information |
|-----------|-----------|--|
| UINT | 0 to 1500 | Values in mV Bus controller default: 1200 |

9.16.6.9.7.6 Configuring the delay time after errors

Name:

SinCosQuitTime

If an error is detected on the analog interface, the last correctly read values remain valid. An interval can be defined in this register at which the module begins receiving correct values again after the error state without processing them further internally. Only then will newly sampled correct analog values be recognized as valid.

| Data type | Value | Information |
|-----------|---------------|---|
| UDINT | 0 to 20000000 | Values in μ s Bus controller default: 100000 |

9.16.6.9.8 HIPERFACE

9.16.6.9.8.1 HIPERFACE - Digital interface configuration

HIPERFACE builds upon the RS-485 (EIA-485) specification and permits communication with multiple HIPERFACE slaves.

There are 2 methods available to use the slave data in a PLC program. One is to store the necessary slave values temporarily in the module, where they can then be provided to the CPU. The other is to use the module's FlatStream mode, which supports the full range of commands defined in the HIPERFACE specification.

Additional information regarding the HIPERFACE specification is provided in the "Description of HIPERFACE" document.

HfMode

Name:
HfMode

This register is used to enable the HIPERFACE interface and must always be set to the value 1 for configuration reasons.

| Data type | Value | Information |
|-----------|-------|---------------------------|
| USINT | 1 | Bus controller default: 1 |

HfParity

Name:
HfParity

This register configures the parity bit for the interface.

| Data type | Values | Information |
|-----------|--------|---|
| USINT | 69 | E → even parity bit Bus controller default setting |
| | 78 | N → no parity bit |
| | 79 | O → odd parity bit |

HfCharTimeout

Name:
HfCharTimeout

This register configures the time that the module waits after receiving the last data block to add additional data to the current data packet (frame). When this time expires, the data received thus far is saved in a frame. The transfer is complete and the data can be evaluated.

Information:

Time is specified as a char value in order to ensure identical behavior regardless of the baud rate setting.

| Data type | Values | Information |
|-----------|----------|--|
| USINT | 1 to 255 | Char Bus controller default setting: 55 |

HfBaud

Name:
HfBaud

This register configures the baud rate (transfer rate) of the interface.
The module does not allow a transfer rate of 600 baud.

| Data type | Values | Information |
|-----------|---|--|
| UDINT | 1200, 2400, 4800, 9600, 19200, 38400 | Baud Bus controller default setting: 9600 |

HfRepressErrTime

Name:
HfRepressErrTime

This register configures the minimum time that an error code remains in the "HfErrorCode" register. This makes it possible to ensure that the CPU registers every error that occurs.

| Data type | Value | Information |
|-----------|---------------|--|
| UDINT | 1 to 20000000 | Time in μ s; Bus controller default: 100000 |

HfRefAdr

Name:
HfRefAdr

This module can manage up to 32 HIPERFACE slaves via its digital interface. High-resolution position sampling, however, requires information from both the digital and analog interfaces. The HIPERFACE address of the station whose sine/cosine track is being read by the module is entered in this register. If there is only one slave on the network, the broadcast address (255) can also be used.

| Data type | Values | Information |
|-----------|----------|--|
| USINT | 0 | Operation without sine/cosine track |
| | 64 to 95 | Open address range for max. 32 HIPERFACE slaves. Bus controller default setting: 64 |
| | 255 | Broadcast address |

HfRefWidth

Name:
HfRefWidth

This register is used to set the absolute width for the sampled position. The number of bits must be taken from the data provided by the encoder manufacturer and usually consists of three values:

- 5-bit: Resolution of the digital absolute position
- 2^y -bit: Number of sine/cosine periods per revolution
- x-bit: HIPERFACE data format, number of bits per revolution

The sum of the sampled values results in the HfRefWidth (i.e. $5+x+y$).

| Data type | Values | Information |
|-----------|---------|------------------------------------|
| USINT | 8 to 32 | Bus controller default setting: 32 |

Example:

The position width of the reference station must be 21 when using the 80MPH4.600S111-02 motor. This is because the HIPERFACE encoder being used measures the absolute position with 21-bit data width (the $x = 12$ most significant bits encode the multi-turn information, the next $y = 4$ bits count the sin/cos period within a mechanical revolution and the $z = 5$ least significant bits encode the absolute position within a sin/cos period). If a value > 21 is set (e.g. 32), then the module firmware detects a supposed jump in the absolute position on each zero crossing of the absolute position (i.e. overflow of 21-bit position value of from 0x00000000 to 0x0001FFFF, or vice versa).

9.16.6.9.8.2 HIPERFACE - Read ID

The digital interface provides the option of assigning a HIPERFACE slave a specific ID. Its parameter data can be queried when booting the PLC, for example. Any deviations from the previous hardware constellation can then be handled accordingly in the program.

Configuration

The parameter to be read is specified by 2 registers. One of the registers contains the address of the desired HIPERFACE slave; the other contains a code for the value to be read.

HfAdrIdent

Name:
HfAdrIdent

This register is used to set the HIPERFACE address of the slave with parameters that are to be processed in the module.

| Data type | Values | Information |
|-----------|----------|--|
| USINT | 0 | Identification deactivated Bus controller default setting |
| | 64 to 95 | Open address range for max. 32 HIPERFACE slaves |
| | 255 | Broadcast address (when operating with one slave) |

HfSelectionIdent

Name:
HfSelectionIdent

This register defines the parameters that should be provided in the slave response and buffered in the module's "HfExtByte" on page 2018 register.

| Data type | Values | Values |
|-----------|--------|---|
| USINT | 0 | Serial number Bus controller default setting |
| | 1 | Firmware date |
| | 2 | High part of firmware version |
| | 3 | Low part of firmware version |

Call

After being configured correctly, the selected parameter is transmitted cyclically to the module. There are 8 registers that serve as temporary storage. The module confirms successful receipt by setting the [HfIdentOkByte](#).

HfIdentOk

Name:
HfIdentOk

This register's bits provide information about the validity of the latest ID values in temporary storage.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|----------------------|
| 0 | HfIdentOk01 | 0 | Parameter 01 invalid |
| | | 1 | Parameter 01 valid |
| 1 - 7 | Reserved | - | |

HfRs485Settings

Name:

HfRs485Settings

This register is used to temporarily store the current network configuration expected by the slave. The register value is specifically structured for HIPERFACE.

| Data type | Value |
|-----------|--------------------|
| USINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|------------------------------|-------|------------------------|
| 0 - 2 | Speed code | 001 | 1200 baud |
| | | 010 | 2400 baud |
| | | 011 | 4800 baud |
| | | 100 | 9600 baud |
| | | 101 | 19200 baud |
| | | 110 | 38400 baud |
| 3 | Reserved | - | |
| 4 | Number of parity bits | 0 | No parity bit |
| | | 1 | 1 parity bit |
| 5 | Type of parity bit | 0 | Even |
| | | 1 | Odd |
| 6 | Behavior if a timeout occurs | 0 | Timeout 11/baudrate |
| | | 1 | Timeout 4*11/baud rate |
| 7 | Network behavior | 0 | Bus |
| | | 1 | Direct connection |

HfEncoderType

Name:

HfEncoderType

This register is used to temporarily store the ID of the current encoder. The register value is structured specifically for each slave and must be looked up in the encoder's data sheet.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

HfEepromSize

Name:

HfEepromSize

This register is used to store the size of the EEPROM being used. The number of 16-byte blocks is specified.

| Data type | Values | Values |
|-----------|----------|----------------|
| USINT | 0 to 255 | 16-byte blocks |

HfOptionFlags

Name:

HfOptionFlags

This register is used to store slave-specific hardware and software settings.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

HfFreeMemory

Name:

HfFreeMemory

This register is used to indicate the number of free 16-byte blocks remaining on the HIPERFACE slave.

| Data type | Values | Information |
|-----------|----------|----------------|
| USINT | 0 to 255 | 16-byte blocks |

HfDataFields

Name:

HfDataFields

This register is used to indicate the number of data fields that have been written thus far.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

HfExtByte

Name:

HfExtByte01 to HfExtByte10

These registers provide the respective parameters according to how the "HfSelectionIdent" on page 2016 register is configured.

| Data type | Values |
|-----------|----------|
| USINT | 0 to 255 |

9.16.6.9.8.3 HIPERFACE - Reading additional encoder positions

This module can read up to 2 additional position values via the HIPERFACE interface and provide them to the PLC. Each position value is accompanied by a [timestamp](#).

Configuration

The address must be specified in order to read the position value from the respective HIPERFACE interface. One address register is provided for each position value.

AddPosAdr

Name:

AddPosAdr01 to AddPosAdr02

These registers are used to set the addresses of the HIPERFACE slaves with position values that should be processed in the module.

| Data type | Values | Information |
|-----------|----------|--|
| USINT | 0 | Additional encoder position disabled Bus controller default setting |
| | 64 to 95 | Open address range for max. 32 HIPERFACE slaves |
| | 255 | Broadcast address (when operating with one slave) |

Call

After being configured correctly, the position value is transferred cyclically to the module. Each slave has five registers that serve as temporary storage. The module automatically generates the [timestamp](#) and confirms successful transmission by setting the corresponding [AddPosOk0x](#) bit. The HIPERFACE specification does not specify in which format the parameters must be received. The module therefore provides the position value and time in two variants. Which of the position registers should be used for further processing depends on the HIPERFACE slave. The user is free to define the format of the timestamp.

AddPosOk (byte)

Name:

AddPosOk01 to AddPosOk02

This register's bits provide information about the validity of the last position values in temporary storage.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|---------------------------|
| 0 | AddPosOk01 | 0 | Position value 01 invalid |
| | | 1 | Position value 01 valid |
| 1 | AddPosOk02 | 0 | Position value 02 invalid |
| | | 1 | Position value 02 valid |
| 2 - 7 | Reserved | - | |

AddPosition

Name:

AddPosition01 to AddPosition02

These registers provide the current position values, depending on the register address, as signed 2-byte or 4-byte values.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |
| INT | -32768 to 32767 |

AddPosTime

Name:

AddPosTime01 to AddPosTime02

These registers provide the timestamp of the most recently received position values, depending on the register address, as signed 2-byte or 4-byte values.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values | Information |
|-----------|------------------------------------|--------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime in μ s |
| INT | -32768 to 32767 | |

9.16.6.9.8.4 HIPERFACE - Reading additional analog values

This module can read up to 4 analog values (16-bit) via the HIPERFACE interface and provide them to the PLC. Each analog value is accompanied by a [timestamp](#).

Configuration

The analog value to be read is specified by 2 registers. One of them contains the address of the desired station, and the other the channel of the parameter to be read. An overview of analog values that can be read is provided in the data sheet for the respective slave.

AnalogAdrCh

Name:

AnalogAdrCh01 to AnalogAdrCh04

These registers are used to set the addresses of the HIPERFACE slaves with analog values that should be processed in the module. To query multiple values from one HIPERFACE slave, it may make sense to write the same address to different AnalogAdrCh registers.

| Data type | Values | Information |
|-----------|----------|---|
| USINT | 0 | Additional analog values disabled Bus controller default setting |
| | 64 to 95 | Open address range for max. 32 HIPERFACE slaves |
| | 255 | Broadcast address (when operating with one slave) |

AnalogCh

Name:

AnalogCh01 to AnalogCh04

These registers define the channel to be read that is written by the bus station to the module's temporary storage.

| Data type | Values | Information |
|-----------|------------------------|-----------------------------------|
| USINT | See encoder data sheet | Bus controller default setting: 0 |

Call

After being configured correctly, the analog value is transferred cyclically to the module. There are 5 registers that serve as temporary storage. The module automatically generates the [timestamp](#) and confirms successful transmission by setting the corresponding [AnalogChOk0x](#) bit. The HIPERFACE specification does not specify in which format the parameters must be received. The module therefore provides the value and time in two variants. Which of the value registers should be used for further processing depends on the peripheral equipment. The user is free to define the format of the timestamp.

AnalogChOk (byte)

Name:

AnalogChOk01 to AnalogChOk04

This register's bits provide information about the validity of the values in temporary storage.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|-------------------------|
| 0 | AnalogChOk01 | 0 | Analog value 01 invalid |
| | | 1 | Analog value 01 valid |
| ... | | ... | |
| 3 | AnalogChOk04 | 0 | Analog value 04 invalid |
| | | 1 | Analog value 04 valid |
| 4 - 7 | Reserved | - | |

AnalogChValue

Name:

AnalogChValue01 to AnalogChValue04

These registers provide the current analog values, depending on the register address, as signed or unsigned 2-byte values.

| Data type | Values |
|-----------|-----------------|
| UINT | 0 to 65535 |
| INT | -32768 to 32767 |

AnalogChTime

Name:

AnalogChTime01 to AnalogChTime04

These registers provide the timestamp of the most recently received analog values, depending on the register address, as signed 2-byte or 4-byte values.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values | Information |
|-----------|------------------------------------|--------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime in μ s |
| INT | -32768 to 32767 | |

9.16.6.9 Flatstream communicationFor a description of Flatstream communication, see "[Flatstream communication](#)" on page 3802

9.16.6.9.10 HIPERFACE with FlatStream

HIPERFACE is an asynchronous interface capable of half-duplex communication. Various features have been included to ensure that signals are transmitted without errors.

- The user can choose to have a parity bit added when transmitting a data block.
- A checksum is sent together with a signal and evaluated by the receiver.
- The command to which the encoder is responding is repeated at the start of a response.

In FlatStream mode, the module acts as a bridge between the CPU and the HIPERFACE slave. HIPERFACE-specific algorithms have been implemented to monitor timeouts and handle checksums. During normal operation, the user does not have access to these details.

Additional information is provided in the "Description of HIPERFACE" document.

9.16.6.9.10.1 Overview of conventional HIPERFACE commands for FlatStream mode

| Command byte [hex] | Command | Code0 |
|--------------------|--|-------|
| 0x42 | Read position | |
| 0x43 | Set position | • |
| 0x44 | Read analog value | |
| 0x46 | Read counter | |
| 0x47 | Increment counter | |
| 0x49 | Delete counter | • |
| 0x4A | Read data | |
| 0x4B | Save data | |
| 0x4C | Read status of a data field | |
| 0x4D | Create data field | |
| 0x4E | Read available memory area | |
| 0x4F | Change access key | |
| 0x50 | Read encoder status | |
| 0x52 | Read nameplate | |
| 0x53 | Reset encoder | |
| 0x55 | Allocate encoder address | • |
| 0x56 | Read serial number and program version | |
| 0x57 | Configure serial interface | • |

Code0 is a byte that was added to the transfer protocol for safety reasons. It protects important system parameters from being overwritten by mistake (default: Code0 = 0x55).

9.16.6.9.10.2 Read position (0x42)

Master command

| Protocol bytes | | Information |
|----------------|---------|--------------------------------|
| No. | Name | |
| Master | | |
| 1 | Address | Address of the HIPERFACE slave |
| 2 | 0x42 | Command byte (read position) |
| Slave | | |

Slave response

9.16.6.9.10.4 Read analog value (0x44)

Master command

| Protocol bytes | | Information |
|----------------|---------|---|
| No. | Name | |
| Master | | |
| 1 | Address | Address of the HIPERFACE slave |
| 2 | 0x44 | Command byte (read analog value) |
| 3 | channel | Channel byte (selects desired analog value) |
| Slave | | |

Slave response

| Protocol bytes | | Information |
|----------------|---------|--|
| No. | Name | |
| Slave | | |
| 1 | Address | Repeated address, command byte and channel byte (safety) |
| 2 | 0x44 | |
| 3 | channel | |
| 4 | Value_H | Value read |
| 5 | Value_L | |
| Master | | |

9.16.6.9.10.5 Read counter (0x46)

Master command

| Protocol bytes | | Information |
|----------------|---------|--------------------------------|
| No. | Name | |
| Master | | |
| 1 | Address | Address of the HIPERFACE slave |
| 2 | 0x46 | Command byte (read counter) |
| Slave | | |

Slave response

| Protocol bytes | | Information |
|----------------|---------|--|
| No. | Name | |
| Slave | | |
| 1 | Address | Repeated address and command byte (safety) |
| 2 | 0x46 | |
| 3 | Ctr_H | Counter value |
| 4 | Ctr_M | |
| 5 | Ctr_L | |
| Master | | |

9.16.6.9.10.6 Increment counter (0x47)

Master command

| Protocol bytes | | Information |
|----------------|---------|----------------------------------|
| No. | Name | |
| Master | | |
| 1 | Address | Address of the HIPERFACE slave |
| 2 | 0x47 | Command byte (increment counter) |
| Slave | | |

Slave response

| Protocol bytes | | Information |
|----------------|---------|--|
| No. | Name | |
| Slave | | |
| 1 | Address | Repeated address and command byte (safety) |
| 2 | 0x47 | |
| Master | | |

9.16.6.9.10.7 Clear counter (0x49)

Master command

| Protocol bytes | | Information |
|----------------|---------|--|
| No. | Name | |
| Master | | |
| 1 | Address | Address of the HIPERFACE slave |
| 2 | 0x49 | Command byte (clear counter) |
| 3 | Code0 | Safety byte in accordance with the HIPERFACE specification |
| Slave | | |

Slave response

| Protocol bytes | | Information |
|----------------|---------|--|
| No. | Name | |
| Slave | | |
| 1 | Address | Repeated address and command byte (safety) |
| 2 | 0x49 | |
| Master | | |

9.16.6.9.10.8 Read data (0x4A)

Master command

| Protocol bytes | | Information |
|----------------|--------------|---|
| No. | Name | |
| Master | | |
| 1 | Address | Address of the HIPERFACE slave |
| 2 | 0x4A | Command byte (read data) |
| 3 | Data field | ID of data to be read: |
| 4 | Byte address | Number of the data field, start byte within the data field and number of bytes to be read |
| 5 | Count | |
| 6 | Access code | Access code in accordance with the HIPERFACE specification |
| Slave | | |

Slave response

| Protocol bytes | | Information |
|----------------|--------------|---|
| No. | Name | |
| Slave | | |
| 1 | Address | Repeated address, command byte and ID of data to be read (safety) |

| 3 | Data field | |
| 4 | Byte address | |
| 5 | Count | |
| 6...n | Data1...n | Data to be read |
| Master | | |

9.16.6.9.10.9 Save data (0x4B)

Master command

| Protocol bytes | | Information |
|----------------|--------------|--|
| No. | Name | |
| Master | | |
| 1 | Address | Address of the HIPERFACE slave |
| 2 | 0x4B | Command byte (save data) |
| 3 | Data field | ID of data to be saved: Number of the data field, start byte within the data field and number of bytes to be read |
| 4 | Byte address | |
| 5 | Count | |
| 6 | Access code | Access code in accordance with the HIPERFACE specification |
| 7...x | Data1...n | Data to be saved |
| Slave | | |

Slave response

| Protocol bytes | | Information |
|----------------|--------------|--|
| No. | Name | |
| Slave | | |
| 1 | Address | Repeated address, command byte and ID of data to be saved (safety) |
| 2 | 0x4B | |
| 3 | Data field | |
| 4 | Byte address | |
| 5 | Count | |
| Master | | |

9.16.6.9.10.10 Read status of a data field (0x4C)

Master command

| Protocol bytes | | Information |
|----------------|------------|---|
| No. | Name | |
| Master | | |
| 1 | Address | Address of the HIPERFACE slave |
| 2 | 0x4C | Command byte (determine status of a data field) |
| 3 | Data field | Number of the data field |
| Slave | | |

Slave response

| Protocol bytes | | Information |
|----------------|------------|--|
| No. | Name | |
| Slave | | |
| 1 | Address | Repeated address, command byte and number of the data field (safety) |

9.16.6.9.11 NetTime TechnologyFor a description of NetTime Technology, see ["NetTime Technology" on page 3035](#).

9.16.6.9.12 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 100 μ s |

9.16.6.9.13 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 μ s |

9.16.7 X20DS1928

Data sheet version: 1.30

9.16.7.1 General information

The module is equipped with an EnDat encoder interface. The module automatically detects whether an encoder is connected with EnDat 2.1 or EnDat 2.2. This module can be used to evaluate encoders installed in B&R servo motors as well as encoders for external axes (encoders that scan any machine movement). The input signals are monitored. This makes it possible to detect open or shorted lines as well as encoder supply failures.

- EnDat 2.1 and EnDat 2.2 encoder interface
- Encoder input monitoring
- 5 VDC and GND for encoder supply
- NetTime timestamp: Position time

EnDat encoders

EnDat is a standard developed by Johannes Heidenhain GmbH (www.heidenhain.de) that incorporates the advantages of absolute and incremental position measurement and also offers a read/write parameter memory in the encoder. With absolute position measurement, the homing procedure is generally not required. Where necessary a multi-turn encoder should be installed. To save costs, a single-turn encoder and a reference switch can also be used. In this case, a homing procedure must be carried out.

NetTime timestamp for the position

It is not just the position value that is important for highly dynamic positioning tasks, but also the exact time the position is measured. The module is equipped with a NetTime function for this that supplies a timestamp for the recorded position with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.16.7.2 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | Digital signal processing and preparation |  |
| X20DS1928 | X20 digital signal module, 1 EnDat 2.1/2.2 interface, NetTime function | |

9.16.7.4 Status LEDs

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Image | LED | Color | Status | Description |
|---|-----|-------|------------------------|--|
|  | r | Green | Off | Module supply not connected |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | Module supply not connected or everything is OK |
| | | | On | Error or reset state - Possible cause: <ul style="list-style-type: none"> Encoder supply error |
| | | | Single flash | I/O error - Possible causes: <ul style="list-style-type: none"> Sine/Cosine relative position error (open line) Sine/Cosine absolute position error (reference) |
| | | | Double flash | System error - Possible causes: <ul style="list-style-type: none"> EnDat communication error EnDat position error EnDat error defining parameters |
| | | | Triple flash | I/O error and system error |
| | | | Single flash, inverted | Error or reset state and I/O error |
| | | | Double flash, inverted | Error or reset state and system error |
| | UP | Green | On | The "UP/DN" LEDs are lit depending on the rotational direction and the speed of the connected encoder. The "UP" LED indicates when the encoder position changes in the positive direction. |
| | | | | |

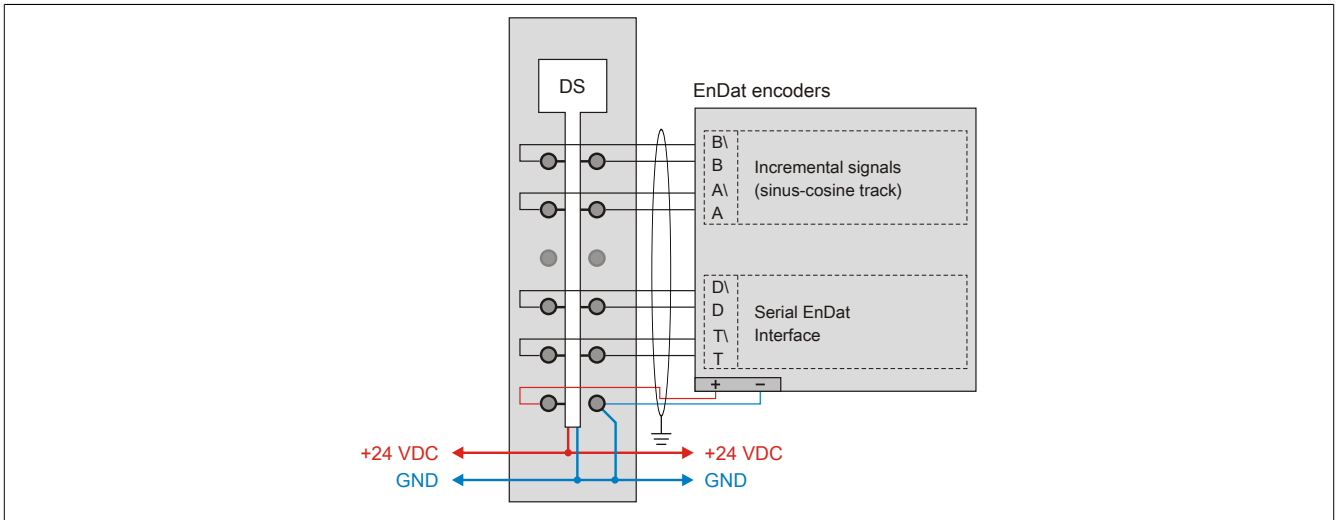

1) Depending on the configuration, a firmware update can take up to several minutes.

9.16.7.5 Pinout

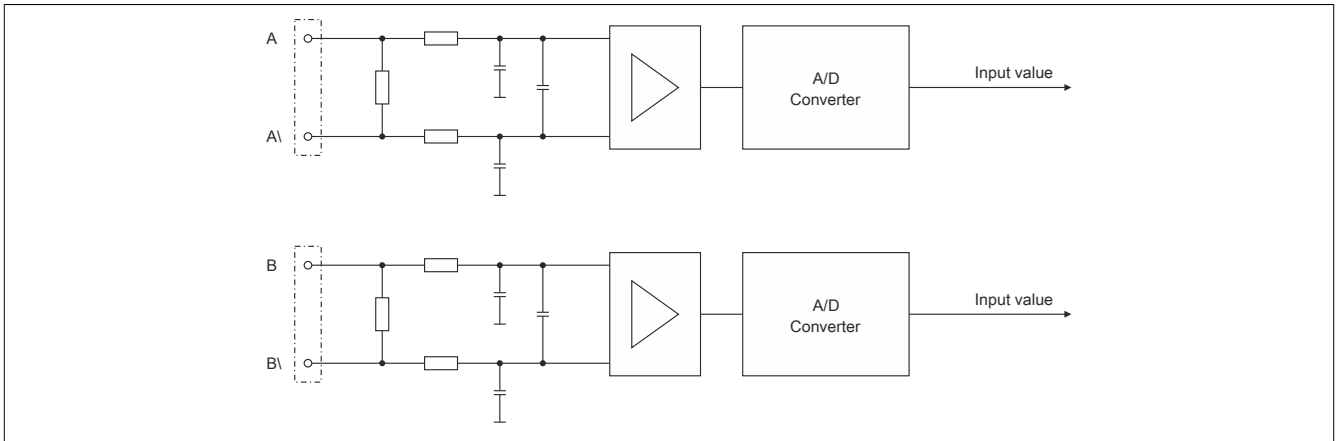

Shielded cables should be used for all signal lines.

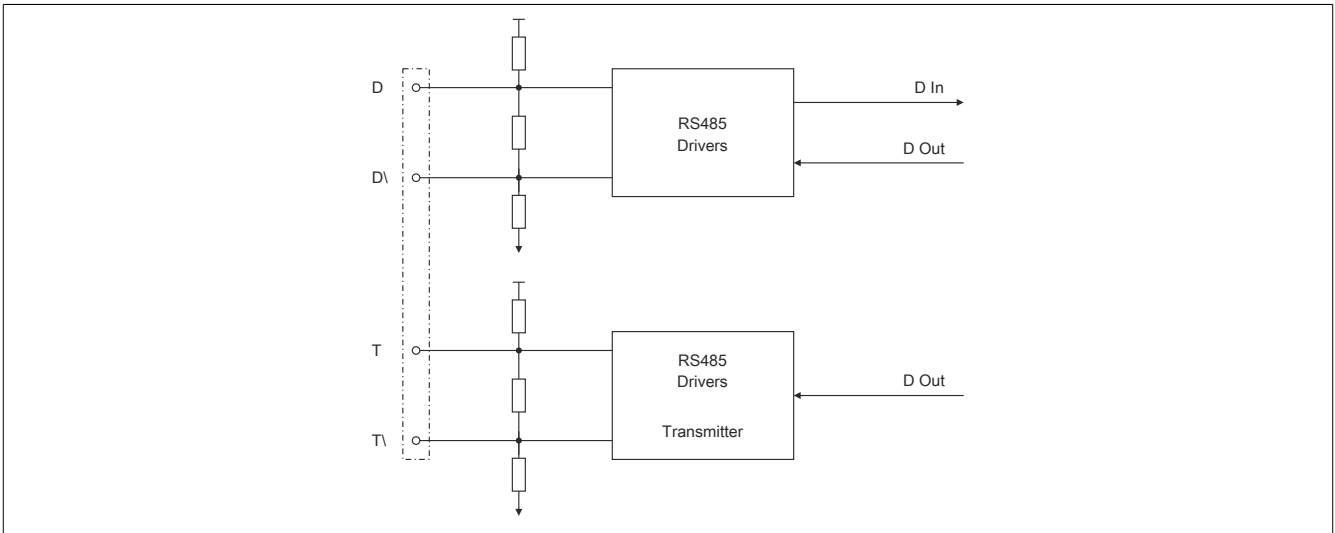

9.16.7.6 Connection example

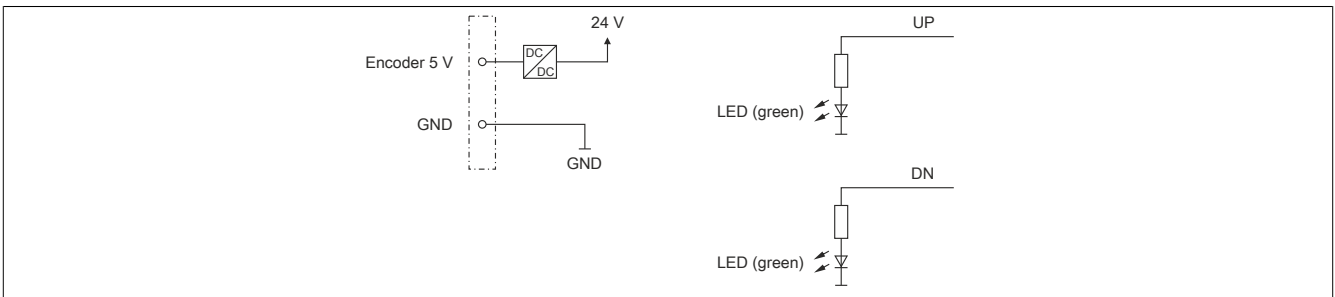

9.16.7.7 Input diagram for the incremental signals (sine-cosine track)

9.16.7.8 Input diagram for the serial EnDat interface

9.16.7.9 Encoder supply scheme and LEDs

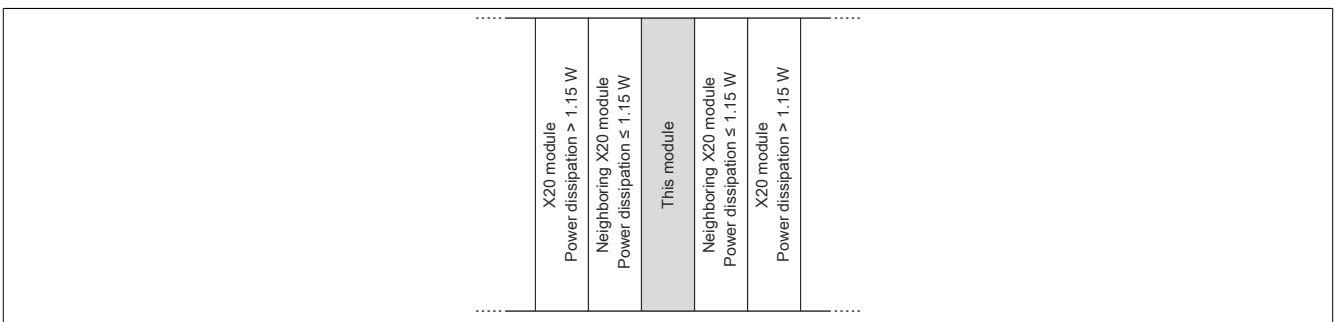

9.16.7.10 Derating

There is no derating when operated below 55°C.

During operation over 55°C, the power dissipation of the modules to the left and right of this module is not permitted to exceed 1.15 W!

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

9.16.7.11 Register description

9.16.7.11.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.16.7.11.2 Register overview - Function model 0 (standard)

| Register | Name | Data type | Read | | Write | |

1) The offset specifies the position of the register within the CAN object.

9.16.7.11.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.16.7.11.3.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.16.7.11.4 Module configuration

The following configuration registers can be used to define various module settings. They can be used, for example, to modify the module's behavior on an X2X Link network. The user can choose between 2 option registers.

9.16.7.11.4.1 Data query

Name:

CfO_SlframeGenID

This register can be used to define when the synchronous/cyclic input data is generated. "X2X cycle optimized" should be set for jitter-free data acquisition. "Fast reaction" can be set for the best performance.

| Data type | Value | Information |
|-----------|-------|--|
| USINT | 9 | Fast reaction |
| | 14 | X2X cycle optimized; Bus controller default |

9.16.7.11.4.2 Prescale factor

Name:

CfO_SystemCyclePrescaler

In order for the module to communicate with the CPU as well as the EnDat encoder, the EnDat cycle time must be at least twice the module cycle time. The actual EnDat cycle time is a result of multiplying the module cycle time by the value in this register.

| Data type | Value | Information |
|-----------|-------|---|
| UINT | 2 | EnDat cycle: 200 to 400 µs (bus controller default setting) |
| | 4 | EnDat cycle: 400 to 800 µs |
| | 8 | EnDat cycle: 800 to 1,600 µs |

9.16.7.11.5 Basic functions

This module can import a position when used together with an EnDat encoder. The received data is prepared in 2 different formats and given a [timestamp](#). 6 registers are available for further processing. This allows the user to choose which format is best suited for individual application.

9.16.7.11.5.1 SDC counter register

Name:

SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

9.16.7.11.5.2 Absolute position values

Name:

PositionHW

PositionLW

The absolute position of the encoder is defined using 64-bit resolution. The position value is stored in the PositionHW and PositionLW registers. The upper 32 bits are stored in the PositionHW register, while the lower 32 bits are stored in the PositionLW register.

For SinCos signal evaluation, see ["Format of the SinCos signal" on page 2045](#) for information regarding the data format.

| Data type | Value |
|-----------|--------------------|
| 2x UDINT | 0 to 4,294,967,295 |

9.16.7.11.5.3 SDC position value

Name:

Position

The SDC library requires a signed 32-bit position value. The position's low word can be accessed separately for this. The value can also be used as default position value, however.

For SinCos signal evaluation, see ["Format of the SinCos signal" on page 2045](#) for information regarding the data format.

| Data type | Value |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

9.16.7.11.5.4 NetTime of the position values

Name:

PosTime

The current NetTime value is assigned to each determined position in this register. The NetTime is recorded with μ s accuracy.

The SDC library requires a 16 bit value. The NetTime value is therefore also prepared in this format.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Value | Information |
|-----------|------------------------------------|--------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime in μ s |
| INT | -32,768 to 32,767 | |

9.16.7.11.5.5 Counter for position values

Name:

PosCycle

PosCycle is an integer counter that is incremented as soon as the module has saved a new valid position value.

| Data type | Value |
|-----------|-------------|
| SINT | -128 to 127 |

9.16.7.11.6 Error management

This module can be used to diagnose error states. There are the following ways in which this is done:

- ["Module-based diagnostics" on page 2040](#)
- ["EnDat-based diagnostics" on page 2043](#)

9.16.7.11.6.1 Module-based diagnostics

The module diagnoses 7 different errors or warnings. Depending on the settings, the error bits can be called either individually or packed together.

Configuring errors and warnings

Name:

ErrorEnableID_1710

The implemented diagnostic algorithms can be enabled or disabled in this register.

| Data type | Value | Bus controller default |
|-----------|--------------------|------------------------|
| USINT | See bit structure. | 255 |

Bit structure:

| Bit | Name | Value | Information |
|-----|----------------------------|-------|--|
| 0 | Encoder supply: | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 1 | Reserved | - | |
| 2 | Vss Sin/Cos: | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 3 | Position error: | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 4 | EnDat - Communication: | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 5 | EnDat - Position: | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 6 | EnDat - Parameters: | 0 | Error detection disabled |
| | | 1 | Error detection enabled (bus controller default setting) |
| 7 | EnDat - Reference warning: | 0 | Warning disabled |
| | | 1 | Warning enabled (bus controller default setting) |

Encoder supply:

The encoder voltage supply is below the permitted limit.

Vss Sin/Cos:

The voltage value for the Sin/Cos track violates the configured limit values.

→ See register ["SinCosVssMin" on page 2046](#) or ["SinCosVssMax" on page 2046](#).

Position error:

The determined position value violates the requirements of the application.

EnDat - Communication:

Communication error on the EnDat interface (e.g. incorrect checksum)

EnDat - Position:

Encoder evaluates the determined position value as invalid.

EnDat - Parameters:

Inconsistent register values for encoder identification

→ Countermeasures: Check wiring or rescan (see ["EnDatAck" on page 2044](#))

EnDat - Reference warning:

The digital interface provides an absolute position value that can be used to accurately describe the axis position. The position value is homed to this absolute value at the beginning of a measurement. The analog interface can be used to incrementally sample changes that occur very rapidly. This enables the module to continue sampling the position value at a high resolution. Both the analog and the digital signal are sampled cyclically. If the value determined incrementally deviates from the absolute value during operation then the referencing warning is displayed and the position must be referenced again.

Status of errors and warnings

Name:

ErrorInfo

EncoderSupplyError

VssCheckError

PositionError

EnDatComError

EnDatPosError

EnDatParsetError

EnDatRefWarning

This register indicates which error or warning is currently active. For a description of errors, see "[Configuring errors and warnings](#)" on page 2040.

| Data type | Value |
|-----------|--------------------|
| USINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|--------------------|-------|----------------------------|
| 0 | EncoderSupplyError | 0 | No error |
| | | 1 | Encoder supply error |
| 1 | Reserved | - | |
| 2 | VssCheckError | 0 | No error |
| | | 1 | Vss error on Sin/Cos track |
| 3 | PositionError | 0 | No error |
| | | 1 | Position error |
| 4 | EnDatComError | 0 | No error |
| | | 1 | EnDat communication error |
| 5 | EnDatPosError | 0 | Error detection disabled |
| | | 1 | Error detection enabled |
| 6 | EnDatParsetError | 0 | Error detection disabled |
| | | 1 | Error detection enabled |
| 7 | EnDatRefWarning | 0 | Warning disabled |
| | | 1 | Warning enabled |

Acknowledging errors and warnings

Name:

AckErrorInfo

AckEncoderSupplyError

AckVssCheckError

AckPositionError

AckEnDatComError

AckEnDatPosError

AckEnDatParSetError

AckEnDatRefWarning

This register is used to acknowledge an error message that occurred in the "Status of errors and warnings" on page 2041 register. For a description of errors, see "Configuring errors and warnings" on page 2040.

| Data type | Value |
|-----------|--------------------|
| USINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|-----------------------|-------|-------------------------|
| 0 | AckEncoderSupplyError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 1 | Reserved | - | |
| | | | |
| 2 | AckVssCheckError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 3 | AckPositionError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 4 | AckEnDatComError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 5 | AckEnDatPosError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 6 | AckEnDatParSetError | 0 | No error acknowledgment |
| | | 1 | Error acknowledgment |
| 7 | AckEnDatRefWarning | 0 | No acknowledgment |
| | | 1 | Acknowledgment |

9.16.7.11.6.2 EnDat-based diagnostics

Memory areas are provided in the EnDat standard for error handling. Error management was tailored to utilize error detection according to the EnDat standard. Additional registers were implemented in the module which prepare these areas in the encoder memory.

The module allows access to all previously defined memory areas for error handling. The memory areas are mirrored in the module registers and can be interpreted by the user.

Detailed information regarding the errors that can be detected in this way can be found in the encoder's manual.

EnDat errors

Name:

EnDatError

This register is used to indicate critical conditions on the EnDat encoder. The system has generally ceased to work and requires service.

| Data type | Value |
|-----------|--------------------|
| UINT | See bit structure. |

The bit structure described below is designed according to the general recommendations of the EnDat standard. The specification does not limit which trigger algorithms to use or which of the listed messages must be supported. Please refer to the encoder's manual for further details.

Bit structure:

| Bit | Name | Value | Information |
|--------|------------------|-------|---------------------------|
| 0 | Illumination | 0 | OK |
| | | 1 | Failed |
| 1 | Signal amplitude | 0 | OK |
| | | 1 | Detected as having errors |
| 2 | Position value | 0 | OK |
| | | 1 | Detected as having errors |
| 3 | Overvoltage | 0 | No |
| | | 1 | Yes |
| 4 | Undervoltage | 0 | No |
| | | 1 | Yes |
| 5 | Overcurrent | 0 | No |
| | | 1 | Yes |
| 6 | Battery | 0 | OK |
| | | 1 | Must be changed |
| 7 - 15 | Reserved | - | |

EnDat warnings

Name:

EnDatWarning

This register is used to indicate critical conditions on the EnDat encoder. Encoder still functional, but must be checked immediately. This generally means that defined tolerances have been exceeded.

| Data type | Value |
|-----------|--------------------|
| UINT | See bit structure. |

The bit structure described below is designed according to the general recommendations of the EnDat standard. The specification does not limit which trigger algorithms to use or which of the listed messages must be supported. Please refer to the encoder's manual for further details.

Bit structure:

| Bit | Name | Value | Information |
|--------|----------------------------|-------|--------------|
| 0 | Frequency collision | 0 | No |
| | | 1 | Yes |
| 1 | Temperature exceeded | 0 | No |
| | | 1 | Yes |
| 2 | Control reserve - Lighting | 0 | Not required |
| | | 1 | Required |
| 3 | Charge - Battery | 0 | OK |
| | | 1 | Low |
| 4 | Reference point | 0 | Reached |
| | | 1 | Not reached |
| 5 - 15 | Reserved | - | |

Acknowledging EnDat errors

Name:

EnDatAck

"EnDatAck" acknowledges all errors and warnings from the "EnDatError" on page 2043 and "EnDatWarning" on page 2044 registers. It can also instruct the module to re-import the parameters for identification.

If one of the bits in this register is set, the system automatically resets it and the respective algorithm is run.

| Data type | Value |
|-----------|--------------------|
| USINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|----------------------------------|-------|------------------------------|
| 0 | EnDatAck | 0 | No acknowledgment |
| | | 1 | Acknowledge |
| 1 | Rescan - Identification register | 0 | Imported parameters retained |
| | | 1 | Reimport parameters |
| 2 - 7 | Reserved | - | |

9.16.7.11.7 Sin/Cos - Analog interface configuration

In addition to the digital EnDat interface, this module is also equipped with an analog interface for sampling a differential sine-cosine signal. To increase the resolution, the EnDat standard specifies a cooperation between the analog and digital information. This enables a highly dynamic representation of the position while maintaining high resolution.

9.16.7.11.7.1 Format of the SinCos signal

The SinCos signal is represented as a position value in the "Absolute position values" on page 2039 and "SDC position value" on page 2039 registers. The following relationships apply:

- PositionLW and Position are identical in the function.
- PositionHW extends the integer range of PositionLW by adding multi-turn functionality.

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|------------------------|----------------------------------|---|---|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 64-bit register | PositionHW (unsigned) | | PositionLW (unsigned) | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 32-bit register | - | | Position (signed) | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Format | Integer extension (to 48-bit) | Integer (16-bit) | Decimal places: (with 13-bit resolution) | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Information | | A full sine wave corresponds to an increment of the integer. | <table border="1"> <tr> <td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td> </tr> <tr> <td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>0</td><td>0</td><td>0</td> </tr> </table> <p>Important: The lower 3 bits always contain the value 0.</p> | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | x | x | x | x | x | x | x | x | x | x | x | x | x | 0 | 0 | 0 |

| Word/DWord | DWord | Word 1 | Word 0 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

Relationship between sine curve (red) and decimal places:

9.16.7.11.7.2 Enabling SinCos

Name:

SinCosEnable

This register must always have the value 1 for configuration reasons.

| Data type | Value | Information |
|-----------|-------|---------------------------|
| USINT | 1 | Bus controller default: 1 |

9.16.7.11.7.3 Enabling SinCos reference source

Name:

SinCosRefSource

This register must always have the value 1 for configuration reasons.

| Data type | Value | Information |
|-----------|-------|---------------------------|
| USINT | 1 | Bus controller default: 1 |

9.16.7.11.7.4 Configuring the lower Vss value

Name:

SinCosVssMin

This register specifies the lower limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value falls below this specified limit, then the module reports the corresponding error.

| Data type | Value | Information |
|-----------|-----------|---|
| UINT | 0 to 1500 | Values in mV Bus controller default: 800 |

9.16.7.11.7.5 Configuring the upper Vss value

Name:

SinCosVssMax

This register specifies the upper limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value exceeds this specified limit, then the module reports the corresponding error.

| Data type | Value | Information |
|-----------|-----------|--|
| UINT | 0 to 1500 | Values in mV Bus controller default: 1200 |

9.16.7.11.7.6 Configuring the delay time after errors

Name:

SinCosQuitTime

If an error is detected on the analog interface, the last correctly read values remain valid. An interval can be defined in this register at which the module begins receiving correct values again after the error state without processing them further internally. Only then will newly sampled correct analog values be recognized as valid.

| Data type | Value | Information |
|-----------|---------------|---|
| UDINT | 0 to 20000000 | Values in μ s Bus controller default: 100000 |

9.16.7.11.8 EnDat

9.16.7.11.8.1 EnDat - Digital interface configuration

The EnDat interface allows you to establish a point-to-point connection with exactly one EnDat encoder.

There are 2 ways to use the encoder data in the PLC program. One is to store the necessary encoder values temporarily in the module, where they can then be provided to the CPU. The other is to use the module's FlatStream mode, which supports the full range of commands defined in the EnDat specification.

Detailed information about the EnDat specification can be found in the document, "Technical Information – EnDat 2.2".

Configuring EnDat module properties

Name:

EnDatMode

This register is used to define various module properties.

| Data type | Value | Bus controller default |
|-----------|--------------------|------------------------|
| USINT | See bit structure. | 0 |

Bit structure:

| Bit | Name | Value | Information |
|-------|----------------------------------|-------|--|
| 0 | EnDat interface | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 1 | Format of imported position data | 0 | Unsigned (bus controller default setting) |
| | | 1 | Signed |
| 2 | Fast EnDat cycle (6 MHz) | 0 | Enabled if encoder compatible (bus controller default setting) |
| | | 1 | Disabled |
| 3 | Sin/Cos track | 0 | Enabled (bus controller default setting) |
| | | 1 | Disabled |
| 4 - 7 | Reserved | - | |

9.16.7.11.8.2 EnDat - Read ID

The EnDat interface does more than just help the user specify axis positions. It can also be used to readout certain data stored in the encoder memory.

The EnDat specification divides the encoder memory into logical groups. These include memory areas for the operating parameters, operating status, manufacturer parameters and manufacturer parameters according to EnDat 2.2.

The 4 most important memory areas are mirrored in the module registers. The information can be accessed in the application and used to identify a particular encoder.

Information:

There are different types of EnDat. Please keep this in mind. EnDat has been continuously expanded to include new technical possibilities while maintaining backward compatibility. Several advancements have been made to the standard, which has resulted in a non-uniform structure.

In general, data is queried from memory for identification purposes when the module is started. In addition, the data can be reimported using the "EnDatAck" on page 2044 register. The module reads the data from the encoder, which is then mapped for the PLC.

Operating Parameters

Name:

OperatingParam_00 to OperatingParam_15

These registers can be used to read out the current operating parameters. The data in these registers correspond exactly to the values on the encoder. More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

| Data type | Value |
|-----------|--------------------|
| 16x UINT | See encoder manual |

Operating state

Name:

OperatingStatus_00 to OperatingStatus_03

This register can be used to read the encoder's current operating state. The first 2 registers from this group are identical to the "EnDatError" on page 2043 and "EnDatWarning" on page 2044 registers. A special setting is provided because they are update cyclically.

Information about write protection and other configuration settings is managed in registers 02 and 03. The data in these registers correspond exactly to the values on the encoder.

More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

| Data type | Value |
|-----------|--------------------|
| 4x UINT | See encoder manual |

Manufacturer parameters

Name:

ParamManuf_04 to ParamManuf_47

These registers are used to prepare the manufacturer parameters according to the EnDat standard 2.1. The exact arrangement of information can be found in the documentation "Technical Information - EnDat 2.2".

| Data type | Value |
|-----------|--|
| 44x UINT | see "Technical Information - EnDat 2.2" or encoder manufacturer data |

Additional manufacturer parameters according to EnDat 2.2

Name:

ParamManufEnDat22_00 to ParamManufEnDat22_63

These registers are used to prepare the manufacturer parameters according to the EnDat standard 2.2. The exact arrangement of information can be found in the documentation "Technical Information - EnDat 2.2".

| Data type | Value |
|-----------|--|
| 64x UINT | see "Technical Information - EnDat 2.2" or encoder manufacturer data |

9.16.7.11.8.3 EnDat - Read additional information

In addition to the identification data, other information can also be accessed from the encoder. However, the following algorithm requires exact knowledge of the encoder's memory structure and the EnDat specification.

Configuration

There are 4 different channels that can be operated during a cycle. One register per channel each is used for configuration, (i.e. determines which data is read from the encoder and mirrored on the respective Info byte).

Transmitting EnDat commands

Name:

EnDatInfoCmd01 to EnDatInfoCmd04

This register controls which data is processed on the corresponding Info byte for each channel. The register consists of up to 4 separate 8-bit values.

| Data type | Value | Bus controller default |
|-----------|--------------------|------------------------|
| 4x UDINT | See bit structure. | 0 |

Bit structure:

| Bit | Name | Information | |
|---------|-------------------|------------------------------|-------------------------------|
| 0 - 7 | Command | Selects the response section | |
| 8 - 15 | Memory area codes | MRS code | |
| | | Parameters not in blocks | Parameters arranged in blocks |
| 16 - 23 | Memory ID | Parameter numbers | Block number |
| 24 - 31 | Memory ID | - | Parameter numbers |

There is a difference when querying data from an encoder using an EnDat 2.1 command or an EnDat 2.2 command. When querying encoder data with an EnDat 2.1 command (0x04 and 0x06), the parameter number and (optionally) the block number must be specified in addition to the MRS code.

When querying the memory with an EnDat 2.2 command, the parameter number and block number are not required. The module consecutively transmits all 4 words of the memory area, which was selected using the MRS code. The right command must be selected depending on which of the 4 response bytes is needed.

Memory area codes

The code to be defined is identical to the MRS code for the encoder memory. The EnDat specification has left a few of the encoders memory areas undefined and available for future developments. This is why a clear and reliable explanation cannot be provided here.

More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

Parameter numbers

EnDat 2.1 requires the corresponding parameter number to be entered in order to specifically address the desired parameter in the encoder memory. Older EnDat versions did not divide the encoder memory into blocks. This is why there are memory areas that can be selected without specifying a block number. In this case, the parameter number must be entered on the third byte.

More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

Block number

To expand the address range of the encoder memory, additional block numbers were added starting at the second section. If the desired parameter is located in this blocked area, then the block number must be specified on the third byte. In this case, the parameter number is entered on the fourth byte.

More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

Call

After being configured correctly, the position value is transmitted cyclically to the module. Each channel has 2 registers that serve as temporary storage. The module confirms successful receipt by setting an OK bit. The EnDat specification does not specify in which format the parameters must be received. Therefore, the module provides the information in 2 ways. Which of the two registers should be used for further processing depends on the parameters being read.

Validity of info data

Name:

EnDatInfoOK01 to EnDatInfoOK04

This register's bits provide information about the validity of the current info data in temporary storage.

| Data type | Value |
|-----------|--------------------|
| USINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|---------------|-------|------------------|
| 0 | EnDatInfoOK01 | 0 | Value 01 invalid |
| | | 1 | Value 01 valid |
| ... | ... | ... | |
| 3 | EnDatInfoOK04 | 0 | Value 04 invalid |
| | | 1 | Value 04 valid |
| 4 - 7 | Reserved | - | |

Reading EnDat information

Name:

EnDatInfo01 to EnDatInfo04

These registers provide the corresponding requested information as a signed or unsigned 2-byte value.

The EnDat specification does not specify the format of the received parameters. Which of the two data types should be used for further processing therefore depends on the parameter being read.

| Data type | Value |
|-----------|-------------------|
| UINT | 0 to 65535 |
| INT | -32,768 to 32,767 |

9.16.7.11.9 Flatstream communication

For a description of Flatstream communication, see ["Flatstream communication" on page 3802](#)

9.16.7.11.10 EnDat with FlatStream

EnDat is a synchronous interface capable of half-duplex communication. Various features have been included to ensure that signals are transmitted without errors.

- An automatically generated checksum is sent together with a signal and evaluated by the recipient.
- The command which the encoder is responding to is repeated at the start of a response.

In Flatstream mode, the module acts as a bridge between the CPU and the EnDat slave. EnDat-specific algorithms were implemented to monitor timeouts and handle checksums. During normal operation, the user does not have access to these details.

More detailed information can be found in the documentation "Technical Information - EnDat 2.2" and the encoder's manufacturer data.

9.16.7.11.10.1 Overview of conventional EnDat commands for the Flatstream mode

| Command byte [hex] | Command | EnDat 2.2 only |
|--------------------|---|----------------|
| 0x00 | Reset | |
| 0x01 | Acknowledge error | |
| 0x04 | Read parameter | |
| 0x05 | Write parameter | |
| 0x06 | Read parameter from memory block | • |
| 0x07 | Write parameter to memory block | • |
| 0x08 | Read word 1 from additional information | • |
| 0x09 | Read word 2 from additional information | • |
| 0x0A | Read word 3 from additional information | • |
| 0x0B | Read word 4 from additional information | • |

9.16.7.11.10.2 Reset (0x00)

Master command

9.16.7.11.11 NetTime Technology

For a description of NetTime Technology, see ["NetTime Technology" on page 3035](#).

9.16.7.11.12 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 100 μ s |

9.16.7.11.13 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 μ s |

9.16.8 X20DS4389

Data sheet version: 2.11

9.16.8.1 General information

This module is a digital signal processor module that is used for detecting and evaluating input edges and for creating edges.

In oversampling mode, the module acquires very short input patterns whose low or high phases are shorter than the X2X Link cycle time. Similarly, output patterns (e.g. drum sequencers) can also be output with extremely short high/low times. Oversampling can take place with a scan rate of up to 25 μ s.

If necessary, up to 4 events per edge detection unit are stored in a buffer (history elements).

Other functions include pulse duration measuring and differential time measuring.

- 4 digital input channels
- 4 digital channels, configurable as inputs or outputs
- 4 edge detection units with timestamp function (each can be used to measure pulse duration or differential time, 4 history elements per unit)
- 4x precise edge generation down to the μ s (up to four edges per unit in each case)
- 4x oversampling (input and output signal)
- 24 VDC and GND for sensor/actuator supply
- NetTime timestamp: Input data, edge detection, edge generation

NetTime-Zeitstempel

An additional essential feature is the module's integrated timestamp function. This allows fast input edges such as registration marks to be detected independently of the system's X2X Link cycle time and provided with a precise input stamp. In the other direction, the module sets outputs at exactly specified times. This is done with a resolution up to 125 ns.

9.16.8.2 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| X20DS4389 | X20 digital signal module, 4 digital inputs, 24 VDC, 4 digital outputs, 24 VDC, 0.1 A, oversampling I/O functions, time-triggered I/O functions, NetTime function |  |

9.16.8.4 LED status indicators

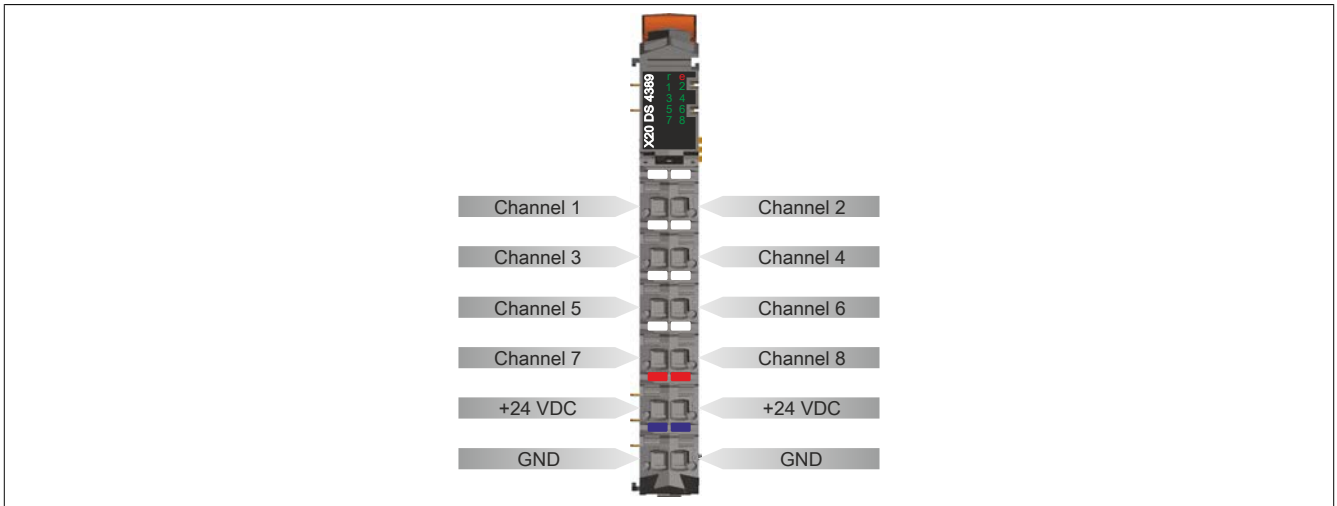

For a description of the various operating modes, see ["Diagnostic LEDs" on page 3787](#).

| Figure | LED | Color | Status | Description |
|---|-------|-------|--------------|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | Double flash | Mode BOOT (during firmware update) ¹⁾ |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Double flash | One of the following errors occurred: <ul style="list-style-type: none"> Oversample output control error Oversample output copy error Edge detect poll cycle violation Error on edge generator unit 1 - 4 |
| | 1 - 8 | Green | | Status of the corresponding digital signal |

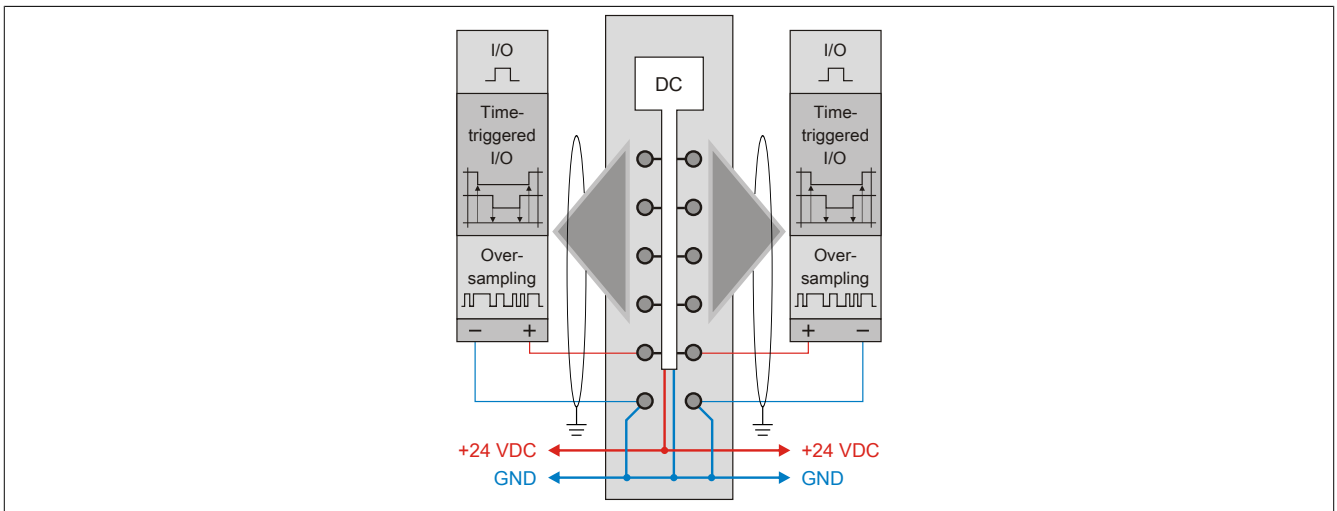

1) Depending on the configuration, a firmware update can take up to several minutes.

9.16.8.5 Pinout

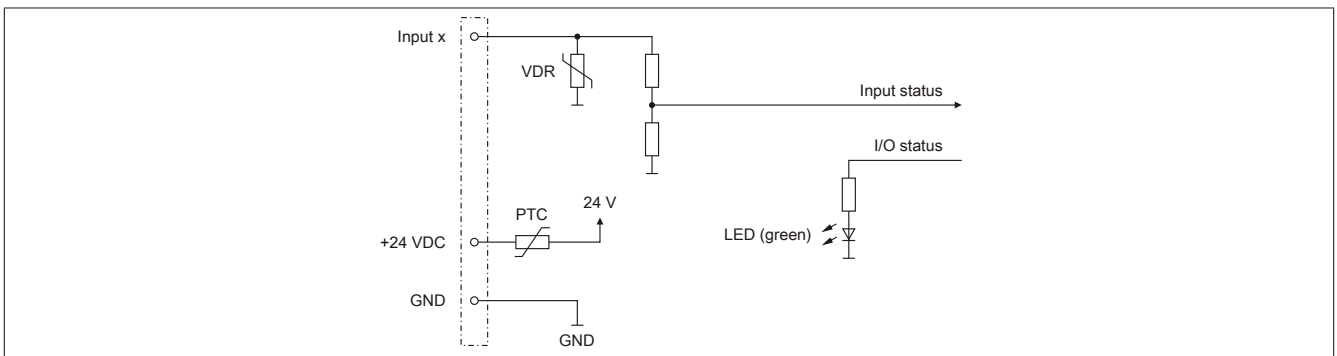

Shielded cables must be used for all signal lines.

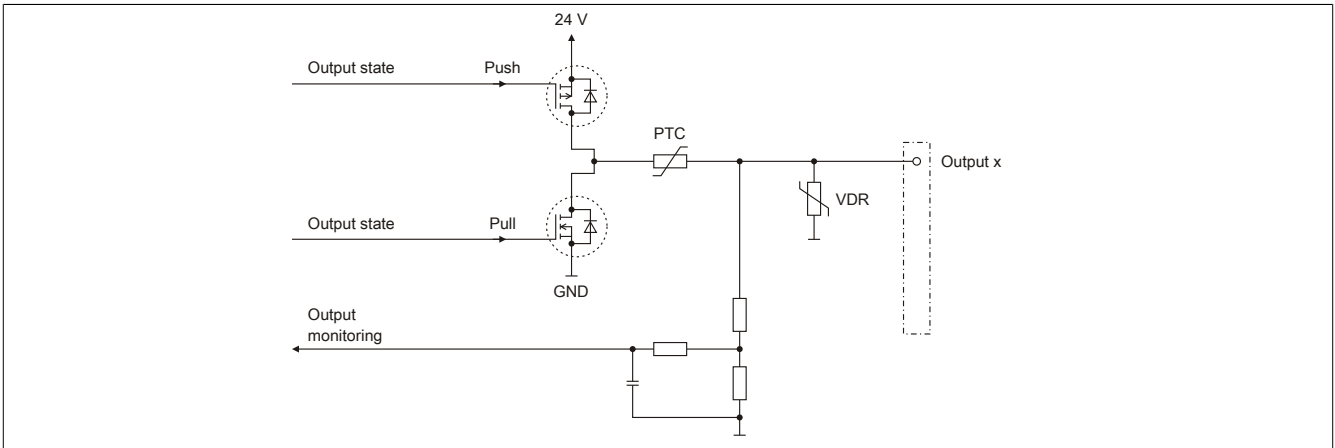

9.16.8.6 Connection example

9.16.8.7 Input circuit diagram

9.16.8.8 Output circuit diagram

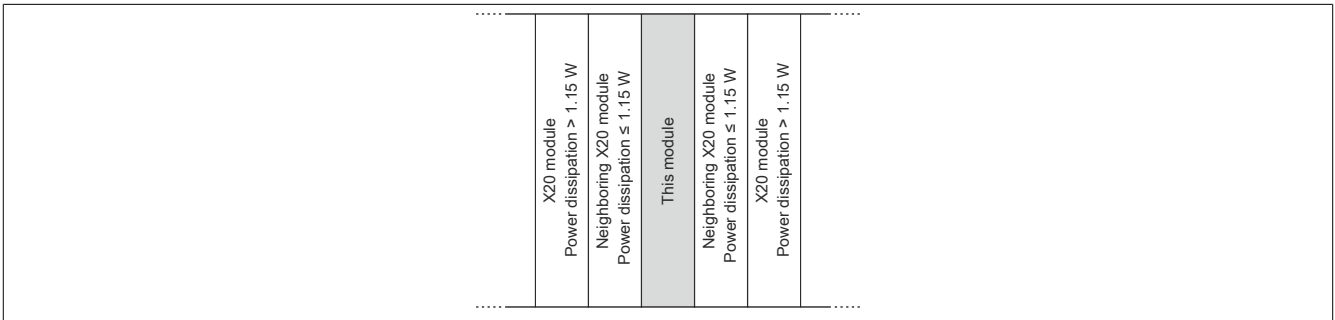

9.16.8.9 Derating

There is no derating when operated below 55°C.

During operation over 55°C, the power dissipation of the modules to the left and right of this module is not permitted to exceed 1.15 W!

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

9.16.8.10 Switching inductive loads

9.16.8.11 Register description

9.16.8.11.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

9.16.8.11.2 Function model 0 - default

9.16.8.11.3 General

9.16.8.11.3.1 Use with Automation Studio

The module is only supported by SG4 target systems via X2X and POWERLINK!

X2X Link supports the following synchronous cyclic data per module:

- 31 bytes input data consisting of 30 input bytes and X2X status byte
- 30 bytes output data

To optimize use and prevent needless data transfer, data points can be adjusted as needed in Automation Studio. Unnecessary data points can be disabled, and the bit width of the data points can be defined.

9.16.8.11.3.2 Timestamp function

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

Conversely, the CPU can predefine output events, apply a timestamp and transfer them to the module. The module then executes the predefined action at the precise moment defined by the CPU.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

The resolution of the timestamp is up to 1/8 μ s in both directions.

Synchronization jitter

Because the CPU – which specifies the X2X NetTime – and the module have different clocks, the module's internal X2X NetTime must be synchronized with the CPU's NetTime. Due to this synchronization, the module's internal X2X NetTime is corrected by a maximum of 1/8 μ s per system cycle if necessary. This synchronization jitter becomes noticeable when using the NetTime with 1/8 μ s resolution (max. \pm 1/8 μ s).

If a 100% exact 1/8 μ s resolution without jitter is required, then the "localtime 1/8 μ s" must be used (see register "[CfO_EdgeDetectUnitMode](#)" on page 2081).

9.16.8.11.4 General registers

9.16.8.11.4.1 Defining the moment for generating synchronous input data

Name:

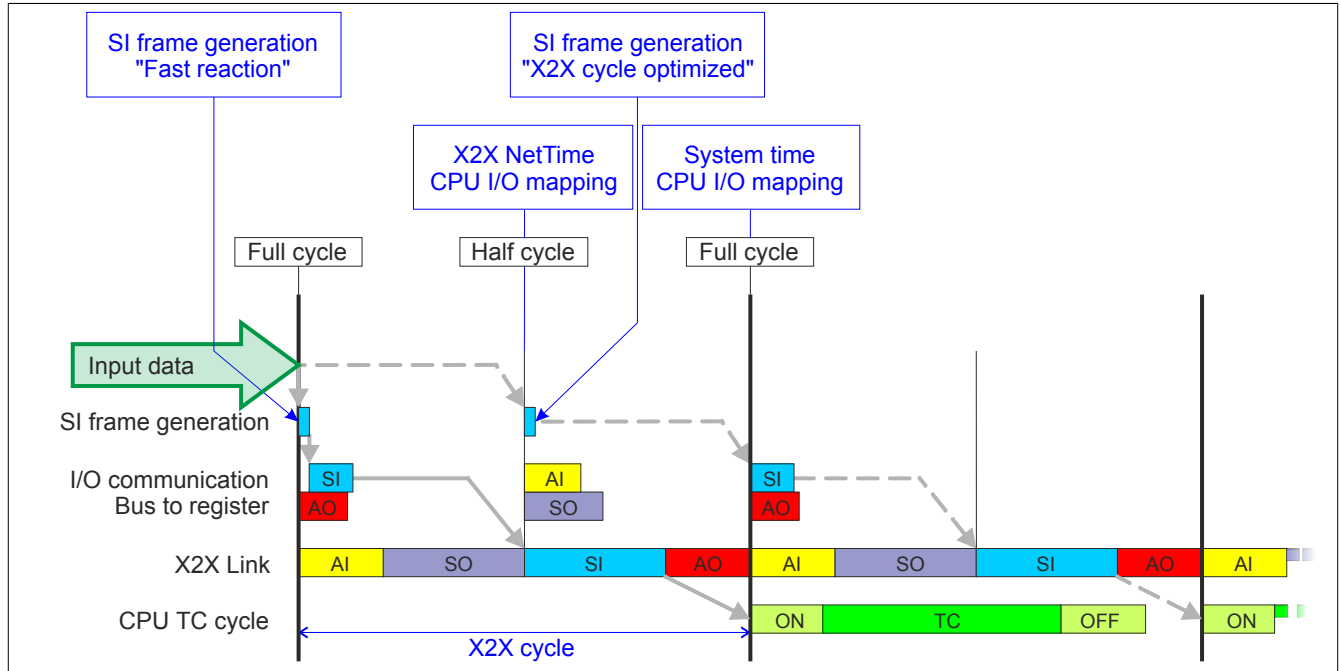

CfO_SlframeGenID

"SI frame generation" in the Automation Studio I/O configuration.

When the synchronous input data is generated for transfer is defined in this register. This has a decisive effect on the timing of the input data.

Setting "Fast reaction" causes the input data to be available one X2X cycle sooner in the CPU. However, this setting also has a negative effect on the minimum X2X cycle time.

| Data type | Values | Information |
|-----------|--------|---------------------|
| USINT | 9 | X2X cycle optimized |
| | 14 | Fast reaction |

9.16.8.11.4.2 Number of X2X protocol errors

Name:

ProtocolError

This register contains an error counter that specifies the number of X2X protocol errors. In the I/O configuration, parameter "Network information" can be used to help configure a data point for this register with a bit width of 8 or 16 bits in the I/O mapping.

| Data type | Values | Information |
|-----------|------------|------------------------|
| USINT | 0 to 255 | Error counter (8-bit) |
| UINT | 0 to 65535 | Error counter (16-bit) |

9.16.8.11.4.3 Number of X2X sequence violations

Name:

ProtocolSequenceViolation

This register contains an error counter that specifies the number of X2X sequence violations. In the I/O configuration, parameter "Network information" can be used to help configure a data point with a bit width of 8 or 16 bits in the I/O mapping.

| Data type | Values | Information |
|-----------|------------|------------------------|
| USINT | 0 to 255 | Error counter (8-bit) |
| UINT | 0 to 65535 | Error counter (16-bit) |

9.16.8.11.4 System clock counter for checking the validity of the data frame

Name:

SDCLifeCount

Counter that is incremented with each system timer cycle. "SDC information" in the Automation Studio I/O configuration can be used to enable this register in the I/O mapping as data point "SDCLifeCount".

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

9.16.8.11.5 Error handling

If one of the functions detects an error, then an error bit is set in one of the error state registers. The application is now able to react to this and acknowledge the errors by setting a respective bit in the "Acknowledge error message" registers. This causes the bit to be reset in the error state register. If the error source persists, then the error bit is set again as soon as the error is detected again (i.e. resetting is not possible).

Error acknowledgment has no effect on the functionality of the module. The module resumes processing, automatically if possible, as soon as the error source is eliminated.

If an error occurs (not a warning), this is indicated by the red "e" LED on the module (double flash). This signal is automatically acknowledged as soon as the error source has been eliminated.

9.16.8.11.5.1 Error state - Output data and edge detection

Name:

OutputControlError

OutputCopyError

EdgeDetectError

Data output errors and cycle time setting errors are indicated in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------|-------|---|
| 0 - 3 | Reserved | - | |
| 4 | OutputControlError | 0 | No error |
| | | 1 | The module did not receive new data in time when "Output control mode = Single", meaning that a bit that has already been output would have been output again by the output control buffer. |
| 5 | OutputCopyError | 0 | No error |
| | | 1 | Oversampling output data could not be copied to the output control buffer (attempted to write to an address outside the oversample output window , for example). |
| 6 | EdgeDetectError | 0 | No error |
| | | 1 | Edge detection cycle time violation: "EdgeDetectPollCycle" must be $\leq 255 \mu\text{s}$. This error is occurs if the cycle set in register "CfO_EdgeDetectPollCycleID" on page 2080 is $> 255 \mu\text{s}$. |
| 7 | Reserved | - | |

9.16.8.11.5.2 Error messages - Edge generator

Name:

EdgeGen01Error to EdgeGen04Error

EdgeGen01Warning to EdgeGen04Warning

This register indicates edge detection errors.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|------------------|-------|------------------------------|
| 0 | EdgeGen01Error | 0 | No error |
| | | 1 | Unit 1 error ¹⁾ |
| 1 | EdgeGen01Warning | 0 | No error |
| | | 1 | Unit 1 warning ²⁾ |
| 2 | EdgeGen02Error | 0 | No error |
| | | 1 | Unit 2 error ¹⁾ |
| 3 | EdgeGen02Warning | 0 | No error |
| | | 1 | Unit 2 warning ²⁾ |
| 4 | EdgeGen03Error | 0 | No error |
| | | 1 | Unit 3 error ¹⁾ |
| 5 | EdgeGen03Warning | 0 | No error |
| | | 1 | Unit 3 warning ²⁾ |
| 6 | EdgeGen04Error | 0 | No error |
| | | 1 | Unit 4 error ¹⁾ |
| 7 | EdgeGen04Warning | 0 | No error |
| | | 1 | Unit 4 warning ²⁾ |

1) Possible errors

- Due to "EdgeGenPollCycle", one or more timestamps from the edge generator of a unit were not able to be processed in time, and it was not possible to catch back up (see register "CfO_EdgeGenUnitPickupDiff" on page 2087).
- A branched ring-shaped chain of edges in a unit is attempting to set the timestamp for an edge even though the FIFO buffer of the configured physical channel is already full (see register "CfO_EdgeGenUnitConfigEdge" on page 2088 → - Ring-shaped chain of edges).

- 2) Due to "EdgeGenPollCycle", one or more timestamps from the edge generator of a unit were not able to be processed in time, and it was possible to catch back up (see register "CfO_EdgeGenUnitPickupDiff" on page 2087).

9.16.8.11.5.3 Acknowledging error messages - Output data and edge detection

Name:

QuitOutputControlError

QuitOutputCopyError

QuitEdgeDetectError

Error messages from register "Error state - Output data and edge detection" on page 2066 can be acknowledged by setting the corresponding bits in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|-------|-------------------|
| 0 - 3 | Reserved | - | |
| 4 | QuitOutputControlError | 0 | No change |
| | | 1 | Acknowledge error |
| 5 | QuitOutputCopyError | 0 | No change |
| | | 1 | Acknowledge error |
| 6 | QuitEdgeDetectError | 0 | No change |
| | | 1 | Acknowledge error |
| 7 | Reserved | - | |

9.16.8.11.5.4 Acknowledge error messages - Edge generator

Name:

QuitEdgeGen01Error to QuitEdgeGen04Error

QuitEdgeGen01Warning to QuitEdgeGen04Warning

The error message from register "[Error messages - Edge generator](#)" on page 2067 can be acknowledged in this register by setting the respective bit.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|----------------------|-------|---------------------|
| 0 | QuitEdgeGen01Error | 0 | No change |
| | | 1 | Acknowledge error |
| 1 | QuitEdgeGen01Warning | 0 | No change |
| | | 1 | Acknowledge warning |
| 2 | QuitEdgeGen02Error | 0 | No change |
| | | 1 | Acknowledge error |
| 3 | QuitEdgeGen02Warning | 0 | No change |
| | | 1 | Acknowledge warning |
| 4 | QuitEdgeGen03Error | 0 | No change |
| | | 1 | Acknowledge error |
| 5 | QuitEdgeGen03Warning | 0 | No change |
| | | 1 | Acknowledge warning |
| 6 | QuitEdgeGen04Error | 0 | No change |
| | | 1 | Acknowledge error |
| 7 | QuitEdgeGen04Warning | 0 | No change |
| | | 1 | Acknowledge warning |

9.16.8.11.6 System timer

The module's individual functions all depend on a system timer. This internal "system cycle time" can be set from 25 to 255 μ s. The functions can also be run using a configurable "prescaled system timer" to minimize the load on the module, thereby making it possible to use the shortest possible X2X cycle time.

The cycle of the "prescaled system timer" (and system timer) is referenced with the X2X Link as soon as the module has been started up and the X2X Link has been initialized. Since the system timer and the module's internal [NetTime](#) use the same clock, the two run synchronously from that point on. An X2X cycle time that is not a multiple of the system cycle time results in an offset, which can be calculated, however.

The following values apply to the following example:

| | |
|------------------------|-------------|
| X2X cycle | 1 ms |
| System timer | 150 μ s |
| Prescaled system timer | 4 |

9.16.8.11.6.1 Setting the cycle time of the system timer

Name:

CfO_SystemCycleTime

"Cycle time" in the Automation Studio I/O configuration.

The cycle time of the system timer can be set in steps of $1/8 \mu$ s in this register. The value entered in the Automation Studio I/O configuration is automatically multiplied by 8.

Information:

A setting $<50 \mu$ s has a negative effect on the minimum X2X cycle time!

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 200 to 2047 | System timer cycle time in steps of $1/8 \mu$ s (25 to 255.875 μ s) |

9.16.8.11.6.2 Offsetting the synchronization moment of the system cycle

Name:

CfO_SystemCycleOffset

"Cycle offset" in the Automation Studio I/O configuration.

The synchronization moment for the system cycle can be offset in steps of $1/8 \mu\text{s}$ in this register. The value entered in the Automation Studio I/O configuration is automatically multiplied by 8.

| Data type | Values | Information |
|-----------|-----------------|---|
| INT | -32768 to 32767 | Cycle offset in steps of $1/8 \mu\text{s}$ (-4096 to 4095.875 μs) |

9.16.8.11.6.3 Configuration of the cycle prescaler

Name:

CfO_SystemCyclePrescaler

"Cycle prescaler" in the Automation Studio I/O configuration.

The prescaler for setting the [prescaled system timer](#) can be configured in this register. The cycle time of the specified system timer is a product of the system timer multiple set in this register.

The "prescaled system timer" can be used as an alternative time source for the individual functions. This is useful if a function requires a very short system cycle. To reduce the load on the module in such a situation, other functions can be processed in a slow cycle.

| Data type | Values | Information |
|-----------|----------|------------------------------|
| UINT | 2 to 128 | Multiple of the system timer |

9.16.8.11.7 Physical I/O configuration

9.16.8.11.7.1 "CfO_PhyIOConfigCh" registers

Name:

CfO_PhyIOConfigCh01 to CfO_PhyIOConfigCh08

The physical I/O channels can each be configured individually in these registers.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------------------------|---------|--------------|
| 0 | Push driver ¹⁾ | 0 | Disabled |
| | | 1 | Enabled |
| 1 | Pull driver ¹⁾ | 0 | Disabled |

| 3 | Output inverted ¹⁾ | 0 | Not inverted |
| | | 1 | Inverse |
| 4 - 7 | Output function ¹⁾ | 0 | Direct I/O |
| | | 1 to 15 | Reserved |

1) Only available for the I/O channels 3, 4, 7 and 8.

9.16.8.11.8 Direct I/O

Direct I/O makes it possible to use the physical I/Os like normal I/Os. Additionally, the application can only set or reset I/Os (e.g. an output channel is set by the edge generator and manually reset by the application).

9.16.8.11.8.1 Direct operation of the output channel - Reset

Name:

CfO_DirectIOClearMask0_7

"Direct operation of output channel 03" to "Direct operation of output channel 08" in the Automation Studio I/O configuration.

If the bit for the respective channel is set in this register, then the output is reset as soon as its direct I/O output channel (register "[DigitalOutput](#)" on page 2071 or "DigitalOutput0x" in the Automation Studio I/O mapping) is reset.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------|-------|---------------|
| 0 - 1 | Reserved | - | |
| 2 | Output channel 3 | 0 | No change |
| | | 1 | Reset channel |
| 3 | Output channel 4 | 0 | No change |
| | | 1 | Reset channel |
| 4 - 5 | Reserved | - | |
| 6 | Output channel 7 | 0 | No change |
| | | 1 | Reset channel |
| 7 | Output channel 8 | 0 | No change |
| | | 1 | Reset channel |

9.16.8.11.8.2 Direct operation of the output channel - Set

Name:

CfO_DirectIOSetMask0_7

"Direct operation of output channel 03" to "Direct operation of output channel 08" in the Automation Studio I/O configuration.

If the bit for the respective channel is set in this register, then the output is set as soon as its direct I/O output channel (register "[DigitalOutput](#)" on page 2071 or "DigitalOutput0x" in the Automation Studio I/O mapping) is set.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------|-------|-------------|
| 0 - 1 | Reserved | - | |
| 2 | Output channel 3 | 0 | No change |
| | | 1 | Set channel |
| 3 | Output channel 4 | 0 | No change |
| | | 1 | Set channel |
| 4 - 5 | Reserved | - | |
| 6 | Output channel 7 | 0 | No change |
| | | 1 | Set channel |
| 7 | Output channel 8 | 0 | No change |
| | | 1 | Set channel |

9.16.8.11.8.3 Direct operation of the output channel - Moment of data output

Name:

CfO_OutputUpdateCycle

The moment when data is output is set with this register.

| Data type | Values | Information |
|-----------|--------|-----------------------------------|
| USINT | 10 | X2X cycle optimized (jitter-free) |
| | 15 | Fast reaction (with jitter) |

9.16.8.11.8.4 "DigitalOutput" register

Name:

DigitalOutput03 and DigitalOutput04, DigitalOutput07 and DigitalOutput08

This register contains the bits for controlling the direct I/O output channels. Depending on how the "[CfO_DirectIO-ClearMask0_7](#)" on page 2070 and "[CfO_DirectIOSetMask0_7](#)" on page 2070 registers are configured, the digital outputs are set to the status of the respective bits in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|--------|----------------------------|
| 0 - 1 | Reserved | - | |
| 2 | DigitalOutput03 | 0 or 1 | Output status of channel 3 |
| 3 | DigitalOutput04 | 0 or 1 | Output status of channel 4 |
| 4 - 5 | Reserved | - | |
| 6 | DigitalOutput07 | 0 or 1 | Output status of channel 7 |
| 7 | DigitalOutput08 | 0 or 1 | Output status of channel 8 |

9.16.8.11.8.5 Input state

Name:

DigitalInput01 to DigitalInput08

The state of the digital input channels is contained in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|----------------|--------|--------------------------|
| 0 | DigitalInput01 | 0 or 1 | Input state of channel 1 |
| ... | ... | ... | |
| 7 | DigitalInput08 | 0 or 1 | Input state of channel 8 |

9.16.8.11.9 Oversampled I/O

"Oversampled I/O" is based on input status buffers and output control buffers. The input data acquisition and output control occur in one sample cycle (one sample cycle corresponds to one bit in the buffer). The precise moment of an input buffer entry is indicated by its position in the buffer and the **NetTime** assigned to the buffer.

When "Output control mode = Single", every output buffer entry is marked as invalid once it has been executed. This ensures that the outputs are not supplied with invalid data. In this mode, the application needs to ensure that the module is always supplied with valid data.

When using "Output control mode = Continuous" the contents of the buffer are output again if the module is not supplied with new oversample output data.

9.16.8.11.9.1 Addressing the output control buffer

The module has one cyclic 256-bit output control buffer for each oversample channel. One bit is output from these buffers to the configured physical output channels in each "sample cycle". When new data is transferred to one of these buffers, the application must define where in the respective buffer the data should be written to. There are 2 possibilities available for this (absolute or relative "Output mode" in the Automation Studio I/O configuration).

9.16.8.11.9.2 Absolute addressing of the output control buffer

With absolute addressing, in each cycle where "OversampleOutputValidate = True", in addition to the oversample output sample data (in the "OversampleOutput0NSample" on page 2078 registers) an address must also be transferred in register "OversampleOutputCycle" on page 2078. This address defines where in the output control buffer the new data should be copied. In order to calculate this address, the contents of register "OversampleInputCycle" on page 2079, which contains the address of the most recently output data, and the transfer time to the module must be taken into account. To help avoid incorrect addressing of the output control buffer, the buffer section that is capable of being written to can be limited using register "OversampleOutputWindow" on page 2076. This window will always be shifted relative to the current sample address. An "OutputCopyError" will be triggered if an attempt is made to write to an address that is outside of this window.

Example

Timing characteristics from the oversample input cycle to the oversample output cycle in absolute output mode ("SI frame generation = Fast reaction", "Output copy cycle = Fast reaction", 8 samples per X2X cycle):

9.16.8.11.9.3 Relative addressing of the output control buffer

When "OversampleOutputValidate = True", then the oversample output sample data is automatically copied to an address relative to the last referenced address at the set **output copy cycle** moment. Register "OversampleSampleOffset" on page 2078 serves as the offset. The new data cannot start being output immediately at the **output copy cycle** moment because it takes time to copy the data from the registers to the buffer. This means that an offset of 0 is not allowed. The relative output control buffer address + offset must point to an address within the "oversample output window". The **oversample output window** is always offset relative to the current sample address. An **OutputCopyError** is triggered if an attempt is made to write to an address that is outside of this window.

9.16.8.11.9.4 Configuration of the output control buffer

Name:

CfO_OversampleMode

"Output mode" in the Automation Studio I/O configuration

"Output control mode" in the Automation Studio I/O configuration

The output control buffer can be configured globally for all channels in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---|-------|---|
| 0 | Addressing the output control buffer "Output mode" | 0 | Absolute addressing of the output control buffer |
| | | 1 | Relative addressing of the output control buffer |
| 1 | Cyclic output control "Output control mode" | 0 | Single - Output control buffer entry is marked invalid after execution. |
| | | 1 | Continuous - Output control buffer entry is not changed. |
| 2 - 7 | Reserved | - | |

Cyclic output control

If cyclic output control is enabled, then all data in the output control buffer is marked invalid as soon as it is output ("Output control mode = Single"). An [OutputControlError](#) is generated if the module does not receive data in time, thereby causing a situation in which a bit that has already been output would be output in the buffer again. In this type of error situation, the output takes on the "Output default state" configured in register "[CfO_OversampleConfigOutput](#)" on page 2077.

If cyclic output control is disabled, then the data is output again if the output control buffer overflows ("Output control mode = Continuous").

Information:

All 256 bits of the output control buffer are always output.

9.16.8.11.9.5 Configuration of the source for the sample cycle

Name:

CfO_OversampleSampleCycleID

"Sample cycle" in the Automation Studio I/O configuration.

The source for the sample cycle is configured in this register. During each sample cycle, one bit from the output control buffers of the oversampled I/O channels is output to the configured physical output, and the status of the configured inputs is read into one bit of the respective input status buffer.

| Data type | Values | Information |
|-----------|--------|---|
| USINT | 2 | System timer The value set in register " CfO_SystemCycleTime " on page 2068 is used as the sample cycle. |
| | 3 | Prescaled system timer The "prescaled system timer" is used as sample cycle. |
| | 10 | AOAI The sample cycle is clocked with the AOAI interrupt of the X2X cycle. |
| | 14 | SOSI The sample cycle is clocked with the SOSI interrupt of the X2X cycle. |

9.16.8.11.9.6 Configuration of the source for the user interface reference cycle

Name:

CfO_OversampleRelativeCycleID

"Reference cycle" in the Automation Studio I/O configuration.

The source for the user interface reference cycle is configured in this register.

- The input data is referenced at the moment of the reference cycle. The referenced data is then copied to the "oversample input sample register" on page 2079 at the moment of SI frame generation, taking into account the oversample input window.
- With relative addressing of the output control buffer, the new sample data is copied to an address relative to the output control buffer address current to the "reference cycle".
- The reference cycle is also used to reference the sample cycle and thus the output data production and input data acquisition (e.g. to the X2X cycle).

| Data type | Values | Information |
|-----------|--------|--|
| USINT | 2 | System timer The value set in register "CfO_SystemCycleTime" on page 2068 is used as the reference cycle. |
| | 3 | Prescaled system timer The prescaled system timer is used as sample cycle. |
| | 10 | AOAI The sample cycle is referenced with the AOAI interrupt of the X2X cycle. |
| | 14 | SOSI The sample cycle is referenced with the SOSI interrupt of the X2X cycle. |

9.16.8.11.9.7 Defining the moment for copying the data to the output control buffer

Name:

CfO_OversampleConsumeCycleID

"Output copy cycle" in the Automation Studio I/O configuration.

At the time of the output copy cycle, data is copied from the "OversampleOutput0NSample" on page 2078 registers into the output control buffer.

When "Output copy cycle = Fast reaction", it is not possible to determine when the data is copied to the output control buffer in either of the two addressing modes. The copy cycles will experience a certain degree of jitter depending on the module load. However, this only affects the moment of the internal copy procedures and therefore the moment of the earliest possible output sample. This will not affect the quality of the output signal. However, "Output copy cycle = Fast reaction" also has a negative effect on the minimum X2X cycle time.

When using the setting "Output copy cycle = X2X cycle optimized", be aware that the sample data cannot start being output immediately at the "Output copy cycle" time due to the internal copy cycle to the output control buffers.

| Data type | Values | Information |
|-----------|--------|---|
| USINT | 10 | X2X cycle optimized The output data is copied to the output control buffer with the AOAI interrupt of the X2X cycle. |
| | 15 | Fast reaction The output data is copied to the output control buffer immediately after being received. |

9.16.8.11.9.8 Number of output bits to be transferred

Name:

CfO_OversampleOutputBits

"User interface size" in the Automation Studio I/O configuration.

Specifies how many bits are transferred from the "OversampleOutput0NSample" on page 2078 registers to the output control buffers at the output copy cycle moment.

| Data type | Values | Information |
|-----------|---------|-------------|
| USINT | 1 to 64 | Output bits |

9.16.8.11.9.9 Number of input bits to be transferred

Name:

CfO_OversampleInputBits

"User interface size" in the Automation Studio I/O configuration.

Specifies how many bits are transferred from the input status buffer to the "OversampleInput0NSample" on page 2079 registers during SI frame generation.

| Data type | Values | Information |
|-----------|---------|-------------|
| USINT | 1 to 64 | Input bits |

9.16.8.11.9.10 Write area in the output control buffer

Name:

CfO_OversampleOutputWindow

"Output control mode" in the Automation Studio I/O configuration.

Defines the area in the output control buffer to which data is permitted to be written. The window is always offset relative to the current sample position. (a value of 128, for example, means that the 128 bits following the current sample cycle can be written to). An [OutputCopyError](#) is triggered if an attempt is made to write output sample data to a location outside of this window.

In Automation Studio, the value for this register is set to 128 bits with "Output control mode = Single" and to 255 bits with "Output control mode = Continuous".

| Data type | Values | Information |
|-----------|----------|---------------|
| USINT | 0 to 255 | Output window |

9.16.8.11.9.11 Defining the moment for referencing input data

Name:

CfO_OversampleInputWindow

"Input mode" in the Automation Studio I/O configuration.

The "oversample input window" defines when the input data is referenced. It is located chronologically before [SI frame generation](#). If the reference moment ("reference cycle" on page 2075) is within this window, then the referenced data from the input status buffer is copied to register "OversampleInput0NSample" on page 2079. If the moment at which the reference occurs is outside the "oversample input window" then the data that is most recent at the moment of "SI frame generation" is copied from the input status buffer to register "OversampleInput0NSample" on page 2079.

This register is limited internally to the value from register "CfO_OversampleInputBits" on page 2075.

Information:

As a result, the [oversample input time](#) and [oversample input cycle](#) are set either at the reference time or at the moment of "SI frame generation".

In Automation Studio, the value for this register is set to 63 with "Input mode = Referenced values" and to 0 with "Input mode = Most recent values".

| Data type | Values | Information |
|-----------|---------|--------------|
| USINT | 0 to 63 | Input window |

9.16.8.11.9.12 Assigning between the physical input channel and oversample I/O input

Name:

CfO_OversampleConfigInput

"Oversample I/O 01 → Input" to "Oversample I/O 04 input" in the Automation Studio I/O configuration.

Which physical input channel an oversample I/O input should be linked to is defined in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------------------|-------|-----------------|
| 0 - 3 | Number of the physical input channel | 0 | Input channel 1 |
| | | .. | |
| | | 7 | Input channel 8 |
| 4 - 7 | Reserved | - | |

9.16.8.11.9.13 Configuring the outputs of the oversampling channels

Name:

CfO_OversampleConfigOutput

"Oversample I/O 01 → Output" to "Oversample I/O 04 → Output" in the Automation Studio I/O configuration

"Oversample I/O 01 → Output control" to "Oversample I/O 04 → Output control" in the Automation Studio I/O configuration

"Oversample I/O 01 → Output default value" to "Oversample I/O 04 → Output default value" in the Automation Studio I/O configuration

This register helps configure the outputs of the individual oversample channels.

The "Output default state" bits define which level the respective output takes on before oversampling is started. In addition, the output is set to the defined "Output default state" in the event of an error.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---|-------|---|
| 0 - 3 | Number of the physical output channel "Oversample I/O 0x → Output" | 2 | Output channel 3 |
| | | 3 | Output channel 4 |
| | | 6 | Output channel 7 |
| | | 7 | Output channel 8 |
| 4 | Output: Clear "Oversample I/O 0x → Output control" | 0 | Output cannot be reset by the oversample channel. |
| | | 1 | Output can be reset by the oversample channel. |
| 5 | Output: Set "Oversample I/O 0x → Output control" | 0 | Output cannot be set by the oversample channel. |
| | | 1 | Output can be set by the oversample channel. |
| 6 | Default output state: Clear "Oversample I/O 0x → Output default value" | 0 | Output not cleared by default |
| | | 1 | Output cleared by default |
| 7 | Default output state: Set "Oversample I/O 0x → Output default value" | 0 | Output not set by default |
| | | 1 | Output set by default |

9.16.8.11.9.14 Oversampling configuration

Name:

OversampleEnable

OversampleOutputValidate

The oversampling and copy process for the output buffer can be configured in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------|-------|--|
| 0 | OversampleEnable | 0 | Disables oversampling (with the next reference cycle) |
| | | 1 | Enables oversampling (with the next reference cycle) |
| 1 | OversampleOutputValidate | 0 | Disable the copy procedure to the output control buffer. |
| | | 1 | Enables the copy procedure to the output control buffer. <ul style="list-style-type: none"> Used to synchronize the oversampling procedure at startup. This makes it possible to prevent new data from being transferred to the "OversampleOutput0NSample" on page 2078 registers in each X2X cycle. |
| 2 - 7 | Reserved | - | |

9.16.8.11.9.15 Address of the new output sampling data in the output control buffer

Name:

OversampleOutputCycle

When absolute addressing of the output control buffer is being used, this register specifies the address from which the new output sample data should be copied to the output control buffer.

| Data type | Values | Information |
|-----------|----------|--------------------------------------|
| USINT | 0 to 255 | Address of the output control buffer |

9.16.8.11.9.16 Offset of new output sample data

Name:

OversampleSampleOffset

When relative addressing of the output control buffer is being used, this register serves as the offset for the new output sample data. (Sample address at the time of the [reference cycle](#) + Offset = Address to which the new output sample data is copied in the output control buffer).

| Data type | Values | Information |
|-----------|----------|------------------------------|
| USINT | 0 to 255 | Offset of output sample data |

9.16.8.11.9.17 Oversample output sample data

Name:

OversampleOutput01Sample1_8 to OversampleOutput04Sample1_8
 OversampleOutput01Sample9_16 to OversampleOutput04Sample9_16
 OversampleOutput01Sample17_24 to OversampleOutput04Sample17_24
 OversampleOutput01Sample25_32 to OversampleOutput04Sample25_32
 OversampleOutput01Sample33_40 to OversampleOutput04Sample33_40
 OversampleOutput01Sample41_48 to OversampleOutput04Sample41_48
 OversampleOutput01Sample49_56 to OversampleOutput04Sample49_56
 OversampleOutput01Sample57_64 to OversampleOutput04Sample57_64

Contains the oversample output sample data. Up to 64 samples (8 bytes) for each oversample I/O channel can be synchronously transferred with a X2X cycle. This data is copied to the specified address (absolute or relative) in the output control buffer at the set [output copy cycle](#). 1 bit of this data is then output during each "sample cycle" to the physical output that is assigned to the oversample I/O channel.

Bit 0 of "OversampleOutputSample8_1" is copied to the output control buffer first, meaning that it is the first bit that is output. "OversampleOutputSample64_57" bit 7 is the last bit to be output.

| Data type | Values | Information |
|-----------|----------|--------------------|
| USINT | 0 to 255 | Output sample data |

Example

Assignment of "OversampleOutputSample" register data to output signal

**9.16.8.11.9.18 X2X NetTime of the input data**

Name:

OversampleInputTime

This register contains the 2 low-order bytes of the X2X NetTime from the moment at which the oversample input data was referenced. This provides an easy way to accurately calculate the moment of each individual input sample.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Values | Information |
|-----------|-----------------|---|
| INT | -32768 to 32767 | X2X NetTime of the input data in microseconds |

9.16.8.11.9.19 Input status buffer address of the input sample data

Name:

OversampleInputCycle

This register contains the input status buffer address of the input sample data.

In addition, the value in this register can be used to reference an absolute addressing of the output control buffer.

| Data type | Values | Information |
|-----------|----------|-----------------------------|
| USINT | 0 to 255 | Input status buffer address |

9.16.8.11.9.20 Input sample data

Name:

OversampleInput01Sample8_1 to OversampleInput04Sample8_1

OversampleInput01Sample16_9 to OversampleInput04Sample16_9

OversampleInput01Sample24_17 to OversampleInput04Sample24_17

OversampleInput01Sample32_25 to OversampleInput04Sample32_25

OversampleInput01Sample40_33 to OversampleInput04Sample40_33

OversampleInput01Sample48_41 to OversampleInput04Sample48_41

OversampleInput01Sample56_49 to OversampleInput04Sample56_49

OversampleInput01Sample64_57 to OversampleInput04Sample64_57

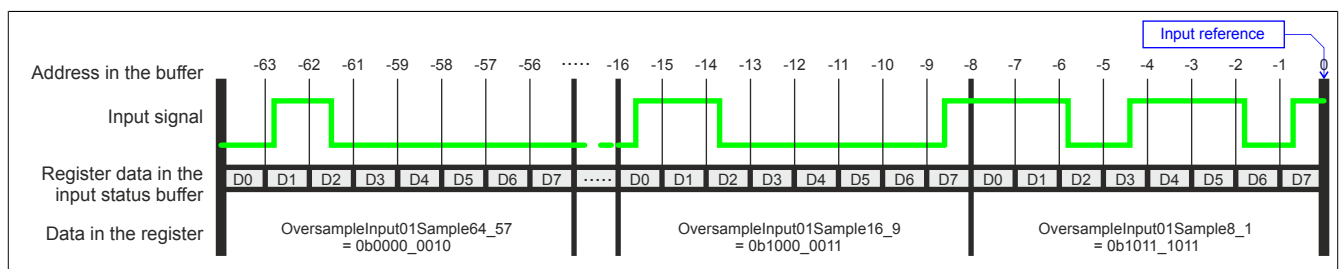

The data of the 4 oversample input status buffers are copied to this register at the moment of **SI frame generation**. A maximum of 64 samples (8 bytes) per oversample I/O channel can be synchronously retrieved from the oversample input status buffer with each X2X cycle.

The most recent input sample bit is stored in "OversampleInputSample8_1" bit 7. The oldest input sample is stored in "OversampleInputSample64_57" bit 0.

| Data type | Values | Information |
|-----------|----------|-------------------|
| USINT | 0 to 255 | Input sample data |

Example

Input signal and resulting data in "OversampleInputSample"

9.16.8.11.10 Edge detection

The module's edge detection function allows edges to be measured with microsecond precision. The concept is based on a maximum of 4 units. One master and one slave edge can be configured for each unit.

At the moment of each master edge, the **NetTime** of the master edge and the **NetTime** of a previous slave edge (if present) are logged. A "master counter" and a "slave counter" can always be used to determine how many edges have been detected since the last X2X cycle.

The module has a history for the timestamp and counters, which can store up to 4 elements per unit. This makes it possible to measure multiple edges precisely within a single X2X cycle.

9.16.8.11.10.1 Configuring the source for the polling cycle

Name:

CfO_EdgeDetectPollCycleID

"Polling cycle" in the Automation Studio I/O configuration.

The source for the polling cycle can be configured in this register.

Information:**The polling cycle must be $\leq 255 \mu\text{s}$. If the configured cycle $> 255 \mu\text{s}$, **EdgeDetectError** occurs.**

| Data type | Values | Information |
|-----------|--------|---|
| USINT | 2 | System timer The time set in register "CfO_SystemCycleTime" on page 2068 is used for the polling cycle. |
| | 3 | Prescaled system timer The time set in register "CfO_SystemCyclePrescaler" on page 2069 is used for the polling cycle. |

9.16.8.11.10.2 Edge detection mode

Name:

CfO_EdgeDetectEventEnable

"Edge detection mode" in the Automation Studio I/O configuration.

The bits in this register define on which edges of the individual input channels an interrupt should be triggered for edge detection.

In mode "Event-triggered", the **NetTime** of each edge is recorded immediately as interrupt. However, an extremely large amount of interrupts within a short amount of time can prevent the module from being able to process any other operations in time!In mode "Polling", only the **NetTime** of the first edge that occurs within a polling cycle is recorded. This ensures that the module is not overloaded by too many edges.

In the Automation Studio I/O configuration, this register is initialized with 0x00000000 when "Edge detection mode = Polling" and with 0xFFFFFFFF when "Edge detection mode = Event-triggered".

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|------------------|-------|--|
| 0 | Physical input 1 | 0 | No interrupt triggered on falling edge |
| | | 1 | Interrupt triggered on falling edge |
| ... | | ... | |
| 7 | Physical input 8 | 0 | No interrupt triggered on falling edge |
| | | 1 | Interrupt triggered on falling edge |
| 8 - 15 | Reserved | - | |
| 16 | Physical input 1 | 0 | No interrupt triggered on rising edge |
| | | 1 | Interrupt triggered on rising edge |
| ... | | ... | |
| 23 | Physical input 8 | 0 | No interrupt triggered on rising edge |
| | | 1 | Interrupt triggered on rising edge |
| 24 - 31 | Reserved | - | |

9.16.8.11.10.3 Setting the time base, slave edge and master edge

Name:

CfO_EdgeDetectUnit01Mode to CfO_EdgeDetectUnit04Mode

"Time base" in the Automation Studio I/O configuration

"Slave edge" in the Automation Studio I/O configuration

"Master edge" in the Automation Studio I/O configuration

When using a time base with 1/8 μ s resolution, keep in mind that the timestamps produced also have a resolution of exactly 1/8 μ s. The respective conversions must be made for calculating in combination with the CPU system time or X2X NetTime.

In addition, synchronization jitter also plays a role when using "Time base = Nettime resolution 1/8 usec" (see "Synchronization jitter" on page 2064). This means that exactly identical input edges can cause slight differences in the results. If 100% exact 1/8 μ s resolution is required, then "Local resolution 1/8 usec" must be used.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------|-------|---|
| 0 - 1 | "Time base" | 0 | Local time 1/8 μ s (Automation Studio: Local resolution 1/8 usec) |
| | | 1 | Local time 1 μ s (Automation Studio: Local resolution 1 usec) |
| | | 2 | NetTime 1/8 μ s (Automation Studio: Nettime resolution 1/8 usec) |
| | | 3 | NetTime 1 μ s (Automation Studio: Nettime resolution 1 usec) |
| 2 - 5 | Reserved | - | |
| 6 | "Slave edge" | 0 | Disabled |
| | | 1 | Enabled |
| 7 | "Master edge" | 0 | Disabled |
| | | 1 | Enabled |

9.16.8.11.10.4 "CfO_EdgeDetectUnitLeading" register

Name:

CfO_EdgeDetectUnit01Leading to CfO_EdgeDetectUnit04Leading

"Slave leading" in the Automation Studio I/O configuration.

When a slave edge occurs, the current NetTime is always saved within the module. A FIFO buffer is provided inside the module that always stores the last 16 slave stamps (even when a master edge occurs).

This value determines from which position the slave time should be retrieved from the FIFO when a master edge occurs. This can be used to measure average periodic signals over multiple cycles.

| Data type | Value | Information |
|-----------|---------|---------------------------------|
| USINT | 0 to 15 | Position in the slave edge FIFO |

9.16.8.11.10.5 Source of the master edge per edge detection unit

Name:

CfO_EdgeDetectUnit01Master to CfO_EdgeDetectUnit04Master

"Master edge" in the Automation Studio I/O configuration.

The source of the master edge for the respective "edge detection unit" is defined in this register.

| Data type | Values | Information |
|-----------|--------|----------------------------------|
| USINT | 0 | Rising edge on physical input 1 |
| | ... | ... |
| | 7 | Rising edge on physical input 8 |
| | 16 | Falling edge on physical input 1 |
| | ... | ... |
| | 23 | Falling edge on physical input 8 |

9.16.8.11.10.6 Source of the slave edge per edge detection unit

Name:

CfO_EdgeDetectUnit01Slave to CfO_EdgeDetectUnit04Slave

"Slave edge" in the Automation Studio I/O configuration.

The source of the slave edge for the respective "edge detection unit" is defined in this register.

| Data type | Values | Information |
|-----------|--------|----------------------------------|
| USINT | 0 | Rising edge on physical input 1 |
| | ... | ... |
| | 7 | Rising edge on physical input 8 |
| | 16 | Falling edge on physical input 1 |
| | ... | ... |
| | 23 | Falling edge on physical input 8 |

9.16.8.11.10.7 "EdgeDetectSlavecount" register

Name:

EdgeDetect01Slavecount to EdgeDetect04Slavecount

The reference pulses of the detected slave edges are counted continuously in this register. The contents of this register are only updated when a master edge occurs. Up to 4 history elements can be enabled for these counters in the Automation Studio I/O configuration. These counters can detect if multiple slave edges occur before a master edge.

| Data type | Value | Information |
|-----------|-------------------|---|
| SINT | -128 to 127 | Number of detected slave edges (8-bit) |
| INT | -32,768 to 32,767 | Number of detected slave edges (16-bit) |

9.16.8.11.10.8 "EdgeDetectDifference" register

Name:

EdgeDetect01Difference to EdgeDetect04Difference

Contains the time difference between a master edge and the last slave edge addressed via "Slave leading".

| Data type | Value | Information |
|-----------|---------------------------------|--|
| INT | -32,768 to 32,767 | Time difference between master/slave edge (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | Time difference between master/slave edge (32-bit) |

9.16.8.11.10.9 Number of detected master edges

Name:

EdgeDetect01Mastercount to EdgeDetect04Mastercount

Detected master edges are counted in this register.

| Data type | Values | Information |
|-----------|-----------------|--|
| SINT | -128 to 127 | Number of detected master edges (8-bit) |
| INT | -32768 to 32767 | Number of detected master edges (16-bit) |

9.16.8.11.10.10 NetTime when a master edge occurs

Name:

EdgeDetect01Mastertime to EdgeDetect04Mastertime

The exact NetTime is copied to this register when a master edge occurs.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values | Information |
|-----------|---------------------------------|--|
| INT | -32768 to 32767 | NetTime master edge in microseconds (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime master edge in microseconds (32-bit) |

9.16.8.11.10.11 "EdgeDetectSlavetime" register

Name:

EdgeDetect01Slavetime to EdgeDetect04Slavetime

In dieses Register wird beim Auftreten einer Masterflanke die exakte NetTime einer eventuell vorher aufgetretenen und durch "Slavevorlauf" adressierten, Slaveflanke kopiert. Pro Masterflanke kann nur eine Slavetime aus dem "Slavevorlauf FIFO" geholt werden. Das Auftreten mehrerer Flanken vor einer Masterflanke kann also nur durch den "EdgeDetectSlavecount" festgestellt werden.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values | Information |
|-----------|------------------------------------|--|
| INT | -32768 to 32767 | NetTime slave edge in μs (16-bit) |
| DINT | -2,147,483,648 to 2,147,483,647 | NetTime slave edge in μs (32-bit) |

History:

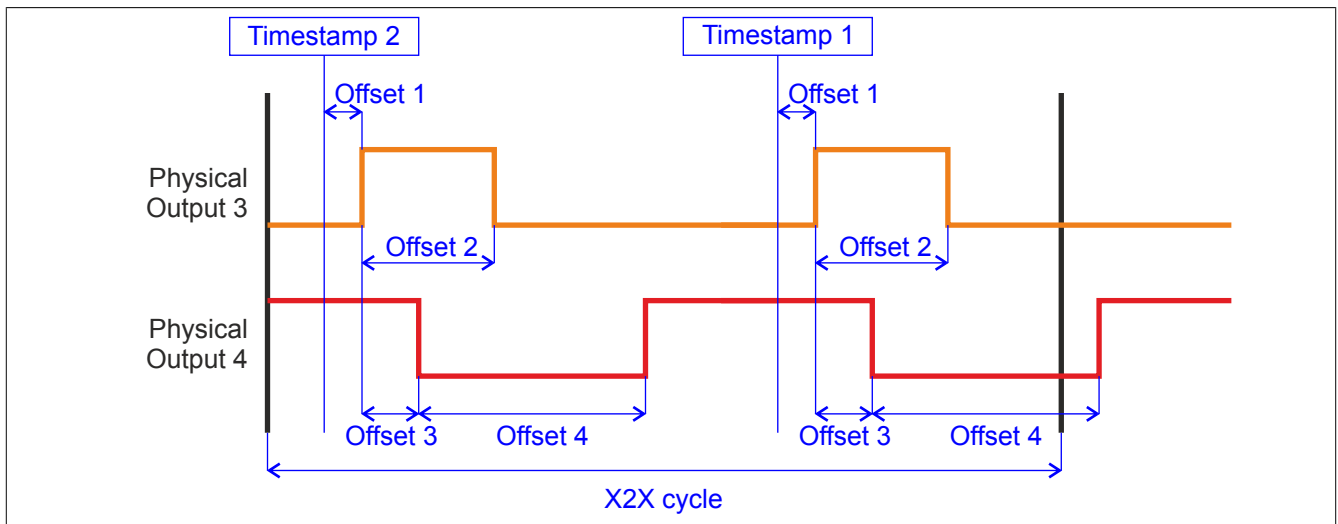

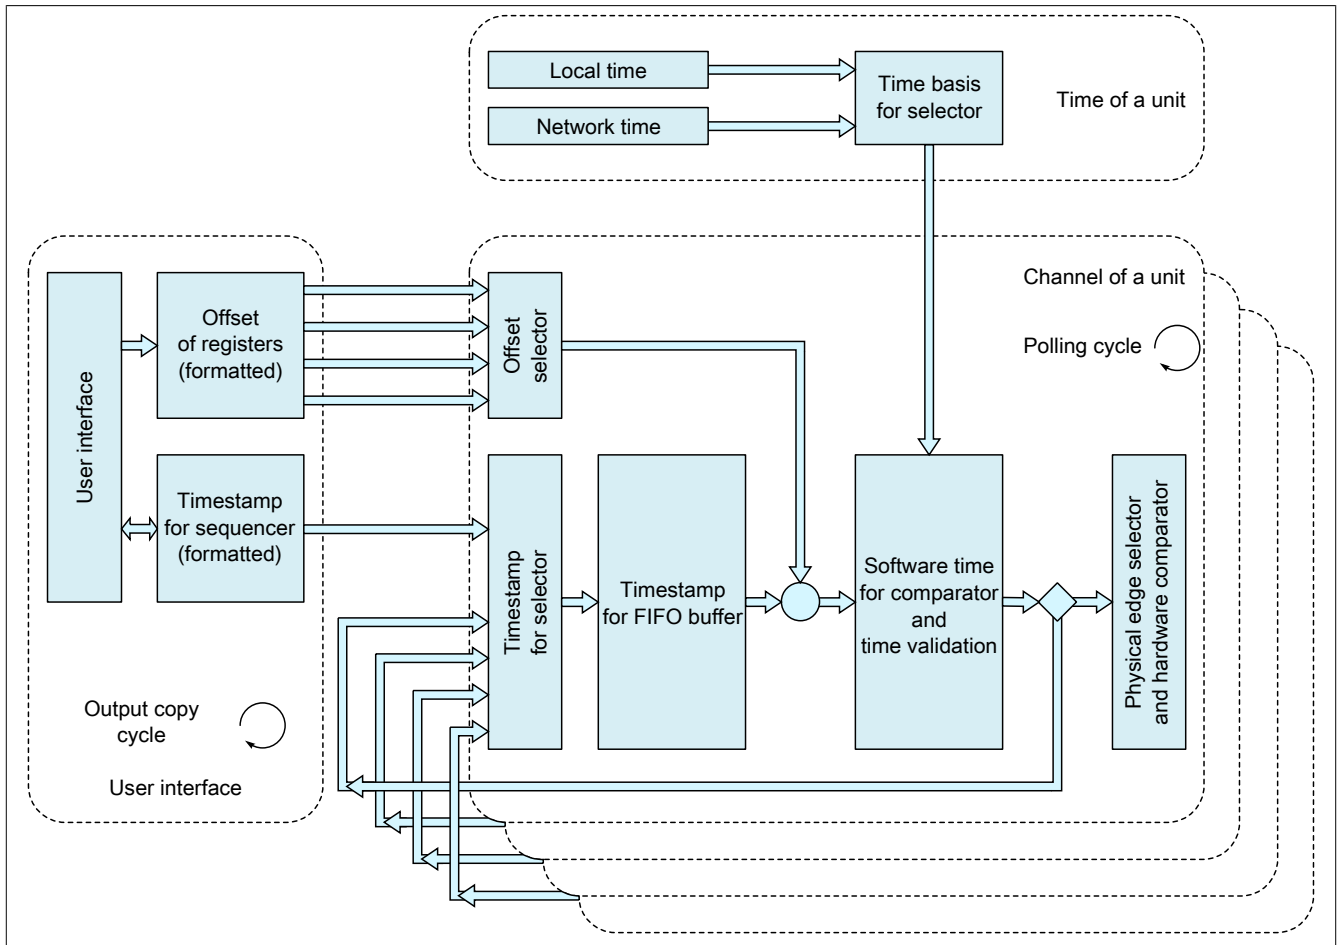

In Automation Studio, a history of up to 4 elements can be enabled in the I/O configuration for the following registers: "[EdgeDetectSlavecount](#)" on page 2082, "[EdgeDetectDifference](#)" on page 2082, "[EdgeDetectMastertime](#)" on page 2082 and "[EdgeDetectSlavetime](#)" on page 2083. Configured history elements are all transferred synchronously with each X2X cycle. This makes it possible to measure multiple edges precisely within a single X2X cycle.

Information:

When the history is enabled, the maximum number of data bytes (28 bytes) that can be transferred synchronously via the X2X Link is reached quickly (especially if 32-bit data points are used).

9.16.8.11.11 Edge generator

The edge generator is based on 4 units. The units are able to generate edges independently of the X2X cycle. For each unit, up to 4 timestamps can be set per X2X cycle. The individual edges can then be referenced to this timestamp or to other edges using an offset.

9.16.8.11.11.1 Mode "DigitalCamSwitch"

"Unit 0x" in Automation Studio I/O configuration.

Starting with upgrade 1.1.0.2, "DigitalCamSwitch" mode can also be selected for each unit when configuring the edge generator in Automation Studio.

In this mode, the entire configuration and operation take place exclusively with the function blocks from the "ASM-cDcs" motion library. For more information, see the corresponding ASM-cDcs function block descriptions.

9.16.8.11.11.2 Preparing data for edge generation by hardware comparators

Name:

CfO_EdgeGenPollCycleEventID

"Generation cycle" in the Automation Studio I/O configuration.

To ensure edge output with μs precision, edge generation is based on internal hardware components. One such comparator is available for one rising and one falling edge respectively for each physical output channel. The data for the comparators is prepared in "EdgeGenPollCycle". Therefore, a maximum of one rising and one falling edge can be generated for each physical output channel per "EdgeGenPollCycle". If **timestamps** are set that cannot be processed in time due to this limitation, then an **EdgeGenWarning** is generated. Processing of such timestamps is made up for as quickly as possible, as long as they are within **EdgeGenUnitPickupDiff**.

A shorter "Generation cycle" means that an enabled edge generator function has a less negative effect on the minimum X2X cycle time.

| Data type | Value | Information |
|-----------|-------|------------------------|
| USINT | 2 | System timer |
| | 3 | Prescaled system timer |

9.16.8.11.11.3 Moment when output data is applied for edge generation

Name:

CfO_EdgeGenConsumeCycleEventID

This register determines when the output data for edge generation is applied within the X2X cycle.

| Data type | Value | Information |
|-----------|-------|--|
| USINT | 10 | "X2X cycle optimized" The data is force-applied between the periods ASYNC IN (AI) and ASYNC OUT (AO). |
| | 15 | "Fast reaction (with jitter)" The data is applied immediately after SYNC OUT (SO) processing. |

Setting "Fast reaction" results in jitter because the copy cycle of the SYNC OUT data can take different amounts of time. However, this only affects the moment at which the internal copy cycle takes place and therefore possibly also the earliest possible timestamp. **Timestamps** that are set outside of this jitter range are not affected by this.

9.16.8.11.11.4 Configuration of units

Name:

CfO_EdgeGenUnit01Mode to CfO_EdgeGenUnit04Mode

"Time base" in the Automation Studio I/O configuration

"Timestamp format" in the Automation Studio I/O configuration

"Offset format" in the Automation Studio I/O configuration

"Unit 01" to "Unit 04" in the Automation Studio I/O configuration

These registers contain the configuration bits for the respective units.

If "Timestamp resolution = 1/8 μ s" is used, it is important to ensure that the timestamp data also has a resolution of 1/8 μ s. Because the CPU system time and the X2X NetTime only have μ s resolution, the system time or the NetTime must be offset by 3 bits to the left or multiplied by 8 in the application. This value can then be used as reference for timestamps with a resolution of 1/8 μ s. It is also possible to use 1/8 μ s timestamps from input edges as a reference.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

When using the NetTime with 1/8 μ s resolution, the synchronization jitter affects the output results (see ["Synchronization jitter" on page 2064](#)).

Because the local time is not synchronized with the CPU system time or the X2X NetTime, this can only be used effectively together with a time source from the module (e.g. input edge timestamp on "local time").

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|-------------|
| 0 | Resolution of the timestamp | 0 | 1 μ s |
| | "Time base" in the Automation Studio I/O configuration. | 1 | 1/8 μ s |
| 1 | Number of bits in the timestamp register | 0 | 16-bit |
| | "Timestamp format" in the Automation Studio I/O configuration. | 1 | 32-bit |
| 2 | Offset resolution | 0 | 1 μ s |
| | "Time base" in the Automation Studio I/O configuration. | 1 | 1/8 μ s |
| 3 | Number of bits in the offset register | 0 | 16-bit |
| | "Offset format" in the Automation Studio I/O configuration. | 1 | 32-bit |
| 4 | Time base | 0 | NetTime |
| | "Time base" in the Automation Studio I/O configuration. | 1 | Local time |
| 5 - 6 | Reserved | - | |
| 7 | Enable/disable units | 0 | Disabled |
| | "Unit 0x" in the Automation Studio I/O configuration. | 1 | Enabled |

9.16.8.11.11.5 Number of timestamps for FIFO

Name:

CfO_EdgeGenUnit01TimestampFifoLim to CfO_EdgeGenUnit04TimestampFifoLim

These registers define how many timestamps can be transferred to the FIFO buffer of a unit. The FIFO buffer serves as a memory buffer for timestamps in the future. Timestamps must be entered in the FIFO buffer in the same order in which they should be output. This means it is not possible to set a timestamp in the future followed by an earlier timestamp. The ["EdgeGenSequenceReadback" on page 2089](#) register can be used to indicate if the defined limit has been reached.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Value | Information |
|-----------|---------|-------------|
| USINT | 1 to 12 | FIFO limit |

9.16.8.11.11.6 Number of timestamps per X2X cycle

Name:

CfO_EdgeGenUnit01TimestampRegCount to CfO_EdgeGenUnit04TimestampRegCount
"Timestamp elements" in the Automation Studio I/O configuration.

This register determines how many timestamps can be transferred per X2X cycle.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Value | Information |
|-----------|--------|------------------------------------|
| USINT | 1 to 4 | Number of timestamps per X2X cycle |

9.16.8.11.11.7 Pickup difference to be regained for timestamps

Name:

CfO_EdgeGenUnit01PickupDiff to CfO_EdgeGenUnit04PickupDiff

These registers determine how far in the past timestamps can be so that they can still be picked up. Timestamps in the past are processed as quickly as possible as long as they fall within the pickup difference specified in this register. [EdgeGenWarning](#) is triggered if a timestamp was not able to be processed in time and its difference had to be regained. If a timestamp could not be picked up because it was outside the pickup difference window, then both "EdgeGenWarning" and "EdgeGenError" are reported.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

In Automation Studio, if "Timestamp format = 16-bit" this register is initialized with 65535 (0xFFFF), and if "Timestamp format = 32-bit" it is initialized with 134,217,728 (0x8000000).

| Data type | Value | Information |
|-----------|------------------|--|
| UDINT | 0 to 65535 | Difference to be regained in μ s when "Offset format = 16-bit" |
| | 0 to 134,217,728 | Difference to be regained in μ s when "Offset format = 32-bit" |

9.16.8.11.11.8 "CfO_EdgeGenUnitConfigEdge" register

Name:

CfO_EdgeGenUnit01ConfigEdge to CfO_EdgeGenUnit04ConfigEdge

"Unit 01→ Edge" to "Unit 04→ Edge" in the Automation Studio I/O configuration.

"Unit 01→ Mode" to "Unit 04→ Mode" in the Automation Studio I/O configuration.

"Unit 01→ Offset" to "Unit 04→ Offset" in the Automation Studio I/O configuration.

"Unit 01→ Unit 01" to "Unit 04→ Unit 04" in the Automation Studio I/O configuration.

The properties of each of the 4 edges of a unit can be configured in this register.

Ring-shaped chain of edges:

If the individual edges are linked together in a ring shape (e.g. edge 2 is relative to edge 1 and edge 1 is relative to edge 2) then a header must be determined for the ring using bit 11 "ring head enable" bit so that this type of cycle can start without timestamp. In Automation Studio, the "ring head enable" bit (bit 11) is set for edge 1 in all units by default. If this type of ring is branched (e.g. a third edge is relative to an edge within the ring) then you must make sure that the internal FIFO, which is available to every physical I/O edge, does not overflow. This happens if more than 12 edges are created by the ring, but should not be output until much later. If this situation occurs, whereby a ring creates edges even though the FIFO is full, then an [EdgeGenError](#) error is generated.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|---|--------|--------------------------|
| 0 - 4 | Physical edge "Unit 0x →Edge" in the Automation Studio I/O configuration. | 2 | Channel 3 rising edge |
| | | 3 | Channel 4 rising edge |
| | | 6 | Channel 7 rising edge |
| | | 7 | Channel 8 rising edge |
| | | 18 | Channel 3 falling edge |
| | | 19 | Channel 4 falling edge |
| | | 22 | Channel 7 falling edge |
| | | 23 | Channel 8 falling edge |
| 5 - 7 | Reserved | - | |
| 8 - 10 | Timestamp of FIFO source "Unit 0x →Mode" in the Automation Studio I/O configuration. | 0 | User interface, absolute |
| | | 1 to 3 | Reserved |
| | | 4 | Edge 1, relative |
| | | 5 | Edge 2, relative |
| | | 6 | Edge 3, relative |
| | | 7 | Edge 4, relative |
| 11 | Ring-shaped chain Default in Automation Studio for "Edge 01 = 1", "Edge 02 = 0", "Edge 03 = 0", "Edge 04 = 0" | 0 | Disabled |
| | | 1 | Enabled |
| 12 - 13 | Offset register numbers "Unit 0x →Offset" in the Automation Studio I/O configuration. | 0 | Offset register 0 |
| | | | |
| | | 1 | Offset register 1 |
| | | 2 | Offset register 2 |
| 14 | Reserved | - | |
| | | | |
| 15 | Switch edge on/off. "Unit 0x →Unit 0x" in the Automation Studio I/O configuration. | 0 | Disabled |
| | | 1 | Enabled |

9.16.8.11.11.9 Enabling units

Name:

EdgeGen01Enable to EdgeGen04Enable

EdgeGen01EnableReadback to EdgeGen04EnableReadback

"Unit 01" to "Unit 04" in the Automation Studio I/O configuration

The different units of the edge generator can be enabled/disabled using this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------------------|-------|-------------|
| 0 | EdgeGen01Enable | 0 | Disabled |
| | EdgeGen01EnableReadback | 1 | Enabled |
| 1 - 7 | Reserved | - | |

9.16.8.11.11.10 Sequence number for generating switching edges

Name:

EdgeGen01Sequence to EdgeGen04Sequence

If new timestamp data is to be applied to the module, then the sequence number must be increased by the number of timestamp elements that must be applied. If multiple elements are transferred within one X2X cycle, then you must make sure that the individual **timestamps** are placed in the FIFO buffer in the same order in which they occur chronologically. Data from **EdgeGenTimestamp** arrives in the FIFO buffer first; data from "EdgeGenTimestamp1" arrives last.

| Data type | Value | Information |
|-----------|-------------|--|
| SINT | -128 to 127 | Sequence number for generating switching edges |

9.16.8.11.11.11 Last sequence number applied by the module for edge generation.

Name:

EdgeGen01SequenceReadback to EdgeGen04SequenceReadback

The sequence number is read back in this register. Like register "**EdgeGenSequence**" on page 2089, this register is incremented if the specified **timestamps** can also be recorded by the module. If the module is not able to record any new timestamps (e.g. because **EdgeGenUnitTimestampFifoLim** has been reached), then this register indicates the number of the last sequence recorded by the module.

| Data type | Value | Information |
|-----------|-------------|--|
| SINT | -128 to 127 | Last sequence number accepted by the module for edge generation. |

9.16.8.11.11.12 Offset formats

Automation Studio provides 3 different parameters for setting offsets.

- **Offset format:** This parameter allows you to select the file type (16- or 32-bit) for cyclic transfer and only affects "**EdgeGenOffset**" on page 2089 registers.
Acyclic transfer of offset values with register "**CfO_EdgeGenOffset_32bit**" on page 2090 is not affected by this parameter and always remains 32 bits wide.
- **Offset 01 to Offset 04:** This parameter has 2 possible settings:
 - Initial configuration: The offset value is only written once during configuration.
 - Cyclic data: A data point is created in the Automation Studio I/O mapping and the offset value is written cyclically.
- **Offset 01 value to Offset 04 value:** The actual offset value.

"EdgeGenOffset" register

Name:

EdgeGen01Offset1 to EdgeGen04Offset1

...

EdgeGen01Offset4 to EdgeGen04Offset4

"Offset 01 value" to "Offset 04 value" in the Automation Studio I/O configuration

The 4 offsets of an edge generator unit are written in this register. Depending on the configuration in register "**Edge generator unit mode**" on page 2086, the offset values are handled in μs or $1/8 \mu\text{s}$ steps.

For information regarding how to use the register and set the offset formats in Automation Studio, see "**Offset formats**" on page 2089.

| Data type | Value | Information |
|-----------|--------------------|--|
| UINT | 0 to 65535 | 16-bit offset |
| UDINT | 0 to 134217728 | Offset when "Offset format = 32-bit" and "Time base" = 1 μs |
| | 0 to 1,073,741,824 | Offset when "Offset format = 32-bit" and "Time base" = $1/8 \mu\text{s}$ |

"CfO_EdgeGenOffset_32bit" register

Name:

CfO_EdgeGen01Offset_32bit1 to CfO_EdgeGen04Offset_32bit1

...

CfO_EdgeGen01Offset_32bit4 to CfO_EdgeGen04Offset_32bit4

The 4 offsets of an edge generator unit can be written acyclically using these registers. Depending on the configuration in register ["Edge generator unit mode"](#) on page 2086, the offset values are handled in μs or $1/8 \mu\text{s}$ steps.

For information regarding how to use the register and set the offset formats in Automation Studio, see ["Offset formats"](#) on page 2089.

| Data type | Value | Information |
|-----------|--------------------|--|
| UDINT | 0 to 134217728 | Offset when "Offset format = 32-bit" and "Time base" = $1 \mu\text{s}$ |
| | 0 to 1,073,741,824 | Offset when "Offset format = 32-bit" and "Time base" = $1/8 \mu\text{s}$ |

9.16.8.11.11.13 Timestamp registers

Name:

EdgeGen01Timestamp1 to EdgeGen04Timestamp1

...

EdgeGen01Timestamp4 to EdgeGen04Timestamp4

Registers for the timestamps to which edges pending generation are referenced. Up to 4 timestamp elements can be transferred per X2X cycle. Between 1 and 4 of these timestamp elements are placed in the FIFO, depending on how much the sequence number is increased by. If an attempt is made to set timestamps to a time that has already passed, then [EdgeGenWarning](#) is generated (see register ["CfO_EdgeGenUnitPickupDiff"](#) on page 2087).

For more information about NetTime and timestamps, see ["NetTime Technology"](#) on page 3035.

| Data type | Value |
|-----------|---------------------------------|
| INT | -32768 to 32767 |
| DINT | -2,147,483,648 to 2,147,483,647 |

9.16.8.11.12 NetTime Technology

For a description of NetTime Technology, see ["NetTime Technology"](#) on page 3035.

9.16.8.11.13 Minimum X2X cycle time

The minimum X2X cycle time is strongly dependent on the configured functions and the resulting load on the module. Setting "Fast reaction" and a very short system cycle ($<50 \mu\text{s}$) generally have a negative effect on the minimum X2X cycle time. This can result in error behavior with short X2X cycle times.

9.17 Dummy modules

The dummy module is used as a placeholder to prevent configuration errors caused by empty slots.

9.17.1 Summary

| Model number | Short description | Page |
|--------------|---|------|
| X20IF0000 | X20 dummy interface module (non-functional) | 2092 |
| X20ZF0000 | Dummy X20 module (non-functional) | 2094 |
| X20ZF0002 | X20 dummy module (no function), 240 VAC coded | 2096 |
| X20ZF000F | Dummy X20 module (non-functional) | 2098 |

9.17.2 X20IF0000

Data sheet version: 1.03

9.17.2.1 General information

Covers for unused interface module slots are included with X20 CPUs. If an X20 system is used in a maritime environment, then the system will be subjected to increased vibration fatigue. In order to achieve the stability necessary for operation, the X20IF0000 dummy interface module from the X20 series is used instead of the covers.

- Cover for unused interface module slots
- IF dummy modules required if the X20 system is subjected to increased vibration fatigue
- Module with no electrical function

9.18 X20 electronics module communication

The CS modules allow complex devices to be remotely connected to the X20 system via a serial interface.

9.18.1 Summary

| Model number | Short description | Page |
|--------------|---|------|
| X20CS1011 | X20 interface module, 1 Moeller SmartWire interface | 2101 |
| X20CS1012 | X20 interface module, 1 M-Bus master interface, integrated slave supply | 2116 |
| X20CS1013 | X20 interface module, 1 DALI master interface | 2136 |
| X20CS1020 | X20 interface module, 1 RS232 interface, max. 115.2 kbit/s | 2147 |
| X20CS1030 | X20 interface module, 1 RS422/485 interface, max. 115.2 kbit/s | 2162 |
| X20CS1070 | X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, object buffers in both send and receive directions | 2177 |
| X20CS2770 | X20 interface module, 2 CAN bus interfaces, max. 1 Mbit/s, object buffers in both send and receive directions | 2194 |
| X20cCS1020 | X20 interface module, coated, 1 RS232 interface, max. 115.2 kbit/s | 2147 |
| X20cCS1030 | X20 interface module, coated, 1 RS422/485 interface, max. 115.2 kbit/s | 2162 |

9.18.2 X20CS1011

Data sheet version: 3.04

9.18.2.1 General information

SmartWire from the company Moeller makes it possible to very easily integrate switching devices such as contactors or motor protection switches in the X20 system without extensive wiring. It replaces the control circuit wiring between the controller and switching devices with pluggable, pre-assembled connection cables.

Although SmartWire is an intelligent connection, this changes almost nothing for the machine programmer. Integration in the X20 system via the interface module cuts down on overall communication. The individual switching devices can simply be viewed as digital inputs and outputs.

Practical applications

SmartWire allows up to 16 switching devices to be connected using pre-assembled cables and attached to the X20 SmartWire interface module. The system can configure itself completely at the push of a button without additional intervention or effort. This replaces the wiring test that was previously necessary.

At the same time, the device configuration is known to the system. If a device is no longer available due to an error or intervention, it will be detected immediately. Once corrected, the system continues to run.

The interface module is designed as a normal electronic module, which means it can be placed anywhere on the remote backplane.

- X2X SmartWire master for controlling up to 16 SmartWire slaves
- Simple connection using pre-assembled connection cables
- Moeller SmartWire modules for Moeller standard switching devices
- Replaces control circuit wiring
- Contactor activation
- Contactor switching status
- Motor circuit breaker status
- 24 VDC control voltage via SmartWire connection cable

- 1) Using an external feed makes it possible to shut down via E-stop or switching relay

9.18.2.4 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|--|-------|-----------------------------|---------------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | | | Single flash | Warning/Error on an I/O channel |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | S + R | Green | | The "S" and "R" LEDs indicate the status of the SmartWire interface. |
| A | Green | Off | U-Aux supply missing or too low | |
| | | On | U-Aux supply OK | |

- 1) Depending on the configuration, a firmware update can take up to several minutes.

"S" and "R" LEDs

The status of the SmartWire interface is indicated by the "S" and "R" LEDs.

| S | R | Firmware status | Description |
|------------------|------------------|-----------------------|---|
| Off | Off | CHECK_INT_FRAM | Initialization |
| | | CHECK_LIN_SUPPLY | Wait until 17 VDC bus is OK |
| | | INT_ERROR_STATE | Internal error has occurred (remains) |
| Off | On | SET_TRANSCIEVER_MODE | Initialization of transceiver |
| | | RESET_UART | Initialization of UART + 10 ms delay |
| | | READ_REVISION_CNT | Initialization (revision counter from FLASH) |
| Blinking slowly | Blinking slowly | INIT_LIN_SCAN | Initialization for bus scan |
| | | RUN_LIN_SCAN | Perform bus scan |
| | | INIT_LIN_SETUP | Initialization for RUN_LIN_SETUP |
| | | RUN_LIN_SETUP | Perform bus setup |
| | | STORE_REVISION_CNT | Revision counter in FLASH |
| | | WAIT_FOR_PUSHBUTTON | Wait for configuration button after bus scan and difference with existing configuration |
| Blinking slowly | Blinking quickly | TIME_DELAY | 4 s optical confirmation signal after pressing the configuration button |
| On | Blinking slowly | DP_CFG_CHECK | Check of the configuration by the higher-level CPU (not currently used) |
| | | SET_SLAVES_TO_OP | Switch SmartWire stack to Operational |
| | | SET_SLAVES_TO_PREOP | Switch SmartWire stack to Preoperational |
| | | INIT_LIN_SCHED | Initialization for RUN_LIN_SCHED |
| On | On | RUN_LIN_SCHED (PREOP) | RUN SmartWire scheduler (in PREOP) |
| | | RUN_LIN_SCHED (OP) | RUN SmartWire scheduler (in OP) |
| Blinking slowly | On | IDLE_STATE | RUN SmartWire without scheduler (no slaves connected) |
| Blinking quickly | On | LIN_ERROR_STATE | ERROR LIN-BUS has occurred (remains) |

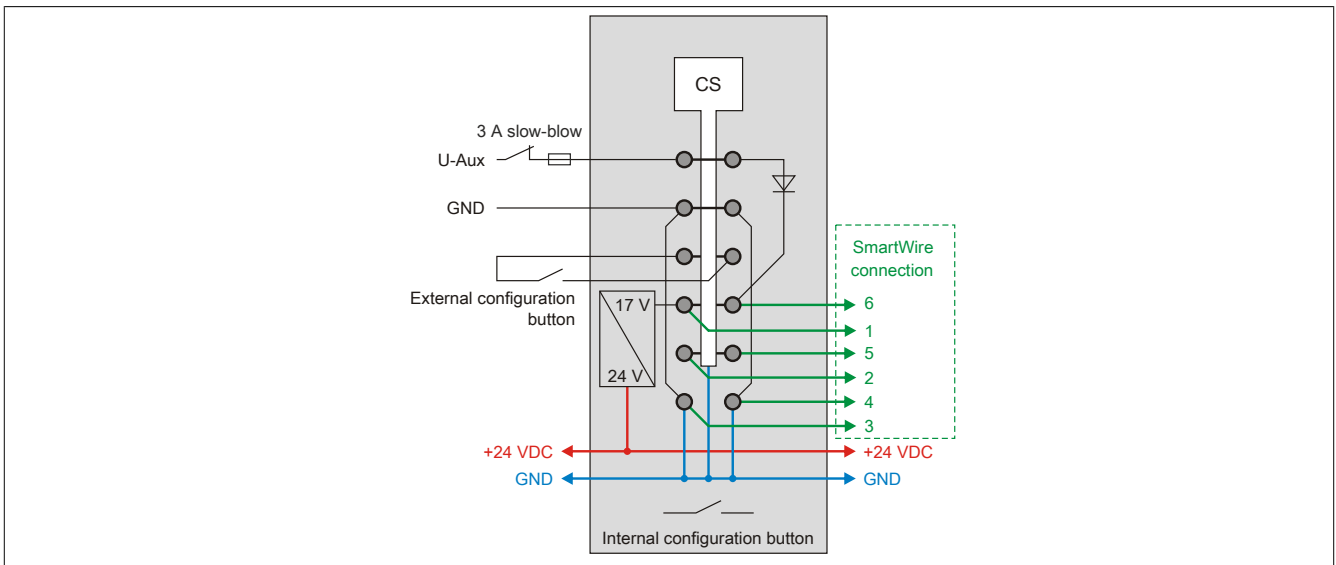

9.18.2.5 Pinout

Information:

X20CA4S00.00xx SmartWire cables are delivered with the X20TB12 terminal block fully installed.

9.18.2.6 Connection example

9.18.2.7 Configuration button

A configuration button is integrated on the underside of the interface module housing. It can be used to completely reconfigure the entire system.

After adding or removing SmartWire sensors/actuators, pressing the configuration button rescans the SmartWire bus and saves the new configuration in the X20 SmartWire interface module.

In addition to the internal configuration button, it is also possible to connect an external configuration button to the terminal block.

9.18.2.8 Register description

9.18.2.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.18.2.8.2 Function model 0 - Standard

| Register | Name | Data type | Read | | Write | |
|----------------------|---|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |

| 513 + (N-1) * 2 | - | SlaveStatusN (Index N = 01 to 16) | USINT | | • | | |
| 8193 + (N-1) * 32 | - | VendorN (Index N = 1 to 16) | USINT | | • | | |
| 8195 + (N-1) * 32 | - | DeviceN (Index N = 1 to 16) | USINT | | • | | |

1) The offset specifies the position of the register within the CAN object.

9.18.2.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "[Using I/O modules on the bus controller](#)" on page 3789.

9.18.2.8.3.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.18.2.8.4 Communication module Basic Master for SmartWire

SmartWire is essentially a master-slave system.

- All data traffic is initiated by the master, but the system can only contain one master.
- The SmartWire master can control up to 16 SmartWire slaves.
- The total scheduling time is 160 ms (i.e. after 160 ms, all 16 slaves have been queried one time).
- The maximum allowed bus extension is 2.6 m.
- Due to the automatic bus configuration, the numbering of the individual slaves is determined by the line structure of the bus.

This results in the following order:

Node address = Physical position in the bus line

9.18.2.8.5 Functions

9.18.2.8.5.1 Scan SmartWire

Automatically started and run after the system is turned on (default settings).

This procedure terminates if

- the set and actual configuration of the bus are identical: system changes to normal operation (i.e cyclic data exchange)
- or if there is a deviation between the set and actual configuration: error present, cyclic data transfer is not started

9.18.2.8.5.2 Setup SmartWire

Can be activated by pressing the configuration button or using a software command:

- if no configuration is saved
- if a SmartWire scan was just terminated due to error

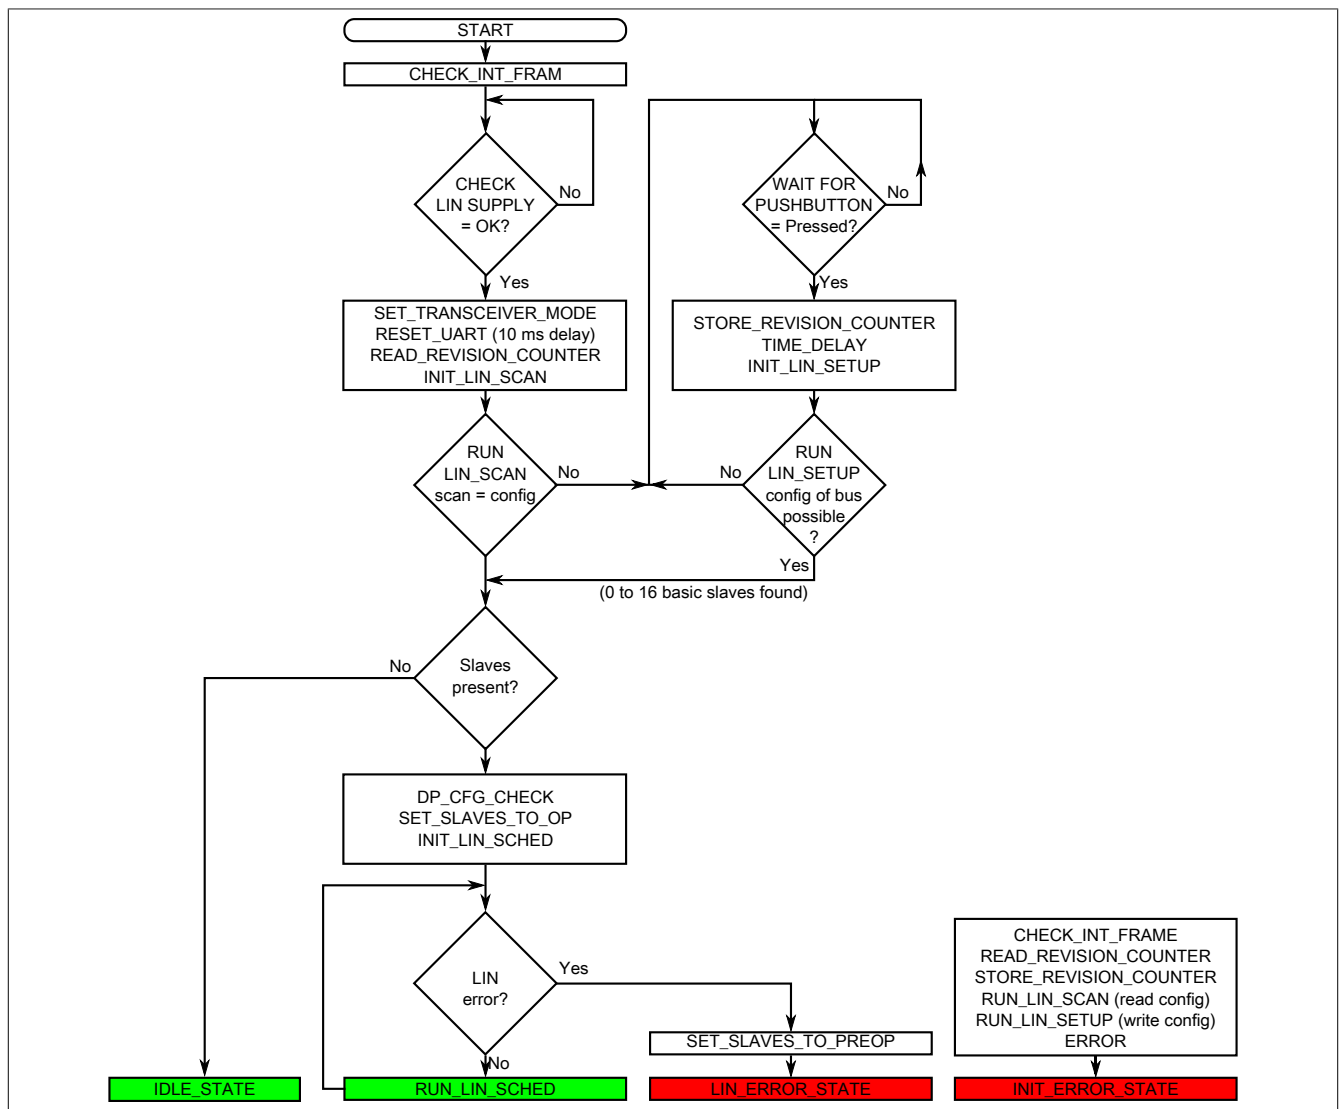

During setup, all connected stations are saved remanently in the master as new set configuration. Valid stations are uniquely identified by the two parameters "[Device ID](#)" on page 2113 and "[Vendor ID](#)" on page 2113.

9.18.2.8.6 Show operating state of the master

The current state of the master state machine is indicated in this register.

| Data type | Value | Code | Description |
|-----------|-------|----------------------|---|
| USINT | 1 | CHECK_INT_FRAM | Init State |
| | 2 | CHECK_LIN_SUPPLY | Waiting for 17 V voltage OK |
| | 3 | SET_TRANSCEIVER_MODE | Turn on transceiver |
| | 4 | RESET_UART UART | Reset |
| | 6 | INIT_LIN_SCAN | Init before bus scan |
| | 7 | RUN_LIN_SCAN | Bus scan is running |
| | 8 | WAIT_FOR_PUSHBUTTON | Scan != Configuration, waiting for Config button |
| | 9 | TIME_DELAY | Delay before bus setup |
| | 10 | INIT_LIN_SETUP | Init before bus setup |
| | 11 | RUN_LIN_SETUP | Bus setup is running (new configuration) |
| | 12 | DP_CFG_CHECK | PLC has set "Wait for configuration" |
| | 15 | SET_SLAVES_TO_OP | Sets slaves to OP mode (after successful scan or setup) |
| | 16 | SET_SLAVES_TO_PREOP | Sets slaves to PREOP mode (after errors have occurred, before LIN_ERROR or INT_ERROR) |
| | 19 | INIT_LIN_SCHED | Init bus scheduling |
| | 20 | RUN_LIN_SCHED | Bus scheduler is running |
| | 21 | LIN_ERROR_STATE | A fatal bus error has occurred (permanent) |
| | 22 | INT_ERROR_STATE | A fatal internal error has occurred (permanent) |
| | 23 | IDLE_STATE | Idle because there is no slave connected (permanent) |

9.18.2.8.6.1 Flow chart of SmartWire master operating status

The register receives the following value after successfully starting:

| Value | Code | Description |
|-------|---------------|--------------------------|
| 20 | RUN_LIN_SCHED | Bus scheduler is running |

9.18.2.8.7 Status of the master

Name:

MasterStatus

The current status information for the master is shown in this register.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|------------------------|-------|---|
| 0 | LIN_BUS_SETUP_COMPLETE | 0 | Saved configuration does not match the actual hardware on the bus |
| | | 1 | Setup finished: SCAN or SETUP after config button is valid |
| 1 | LIN_FATAL_ERROR | 0 | No error on the bus |
| | | 1 | SmartWire bus is defective: e.g. short circuit, no echo → more than 10 consecutive communication errors have occurred. |
| 2 | LIN_MASTER_PREOP | 0 | SmartWire stack not in PREOP mode |
| | | 1 | SmartWire stack in PREOP mode |
| 3 | LIN_MASTER_OP | 0 | SmartWire stack not in OP mode |
| | | 1 | SmartWire stack in OP mode |
| 4 | LIN_GLOBAL_CONTROL | 0 | No command sent |
| | | 1 | Set SmartWire stack to OP mode: Bit is written to the enable bit and can be read back |
| 5 | Reserved | 0 | |
| 6 | LIN_POWER_SUPPLY_STATE | 0 | Bus voltage supply is not OK |
| | | 1 | Bus voltage supply is OK |
| 7 | Reserved | 0 | |
| 8 | DP_CHECK_COMPLETED | 0 | Not a valid configuration |
| | | 1 | Configuration check completed (Not Used) (could optionally be written by the PLC, if the SCAN (configuration) is OK and was able to be read back from here) |
| 9 | Reserved | 0 | |
| 10 | DP_RECONFIGURATION | 0 | X2X Reconfiguration → X2X configuration button not pressed |
| | | 1 | X2X Reconfiguration → X2X configuration button can be read back |
| 11 - 15 | Reserved | 0 | |

The register receives the following value after successfully starting:

Equal to the decimal value: 345

| Bit | Description | Value | Information |
|-----|------------------------|-------|--|
| 0 | LIN_BUS_SETUP_COMPLETE | 1 | SmartWire setup complete: SCAN or SETUP after config button is valid |
| 3 | LIN_MASTER_OP | 1 | SmartWire stack in OP mode |
| 4 | LIN_GLOBAL_CONTROL | 1 | Set SmartWire stack to OP mode - Command set |
| 6 | LIN_POWER_SUPPLY_STATE | 1 | Bus voltage supply is OK |
| 7 | DP_CHECK_COMPLETED | 1 | Configuration is Ok |

9.18.2.8.8 Status of all slaves

Name:
SlaveStatus

The current state of the slave is indicated collectively in this register.

In the event of an error, the failed slaves are indicated in the respective bits, and in the status registers individually set up for the slaves (see "[SlaveStatus1 to SlaveStatus16](#)" on page 2113).

Data is exchanged cyclically as long as none of these bits are set. If an error does error, then I/O transfer is stopped. The bus can be started again after the error has been corrected or a setup has been performed again (see "[Basic application registers "SmartWireEnable" and "SmartWireMode"](#)" on page 2111).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-------------|-------|-------------|
| 0 | Slave 1 | 0 | Ok |
| | | 1 | Errors |
| ... | | ... | |
| 15 | Slave 16 | 0 | Ok |
| | | 1 | Errors |

9.18.2.8.9 Transfer control bits to slaves

Name:
FastOutput01_02 to FastOutput15_16

In these registers, the control bits are transferred to 2 consecutive slaves. Each slave receives 4 control bits, that must be selected from the 8 data bytes depending on the node address (1 to 16). These 4 control bits are assigned fixed values and utilization of the bits by the slave is optional.

All of the slaves evaluate this telegram. It must be sent cyclically by the master so that the slaves can ensure that the master is still functioning without any problems within the monitoring time (lifeguarding time = 400 ms).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-------------|-------|------------------------|
| 0 | Slave N | 0 | Digital output 1 reset |
| | | 1 | Digital output 1 set |
| ... | | .. | |
| 3 | Slave N | 0 | Digital output 4 reset |
| | | 1 | Digital output 4 set |
| 4 | Slave N + 1 | 0 | Digital output 1 reset |
| | | 1 | Digital output 1 set |
| ... | | .. | |
| 7 | Slave N + 1 | 0 | Digital output 4 reset |
| | | 1 | Digital output 4 set |

9.18.2.8.10 Read input data from slave

Name:

Input01 to Input16

Each slave sends its input data and/or its status to the master.

The data volume consumes 1 byte per slave. Each slave has one diagnostics bit, which it sends to the master with the cyclic data. This bit is a message bit if an application error occurs (on the module). It is always located in the highest value bit.

The master can constantly evaluate this bit. The diagnostic bit is set on the slave if the status of the slave is "Error". Slaves that do not have any input data will still send a byte that is used to make their status data available. This is required because the master also monitors the slaves for proper functionality through the receipt of this byte.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------------------------|--------|-----------------------|
| 0 | Input state - Digital input 1 | 0 or 1 | |
| ... | | ... | |
| 3 | Input state - Digital input 4 | 0 or 1 | |
| 4 - 6 | Reserved | 0 | |
| 7 | Error status | 0 | No error on the slave |
| | | 1 | Error on the slave |

9.18.2.8.11 Configure the function breakpoints on the master

Name:

SmartWireEnable

This register can be used to configure function breakpoints that may be implemented in master state machine.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 3 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------------------|-------|---|
| 0 | Enable SmartWire stack | 0 | Disabled |
| | | 1 | Enabled (bus controller default setting) |
| 1 | Set SmartWire stack mode | 0 | Sets PREOP mode (scheduler is already running, output data will still be output with 0) |
| | | 1 | Sets to OP mode (bus controller default setting) |
| 2 | Reserved | 0 | |
| 3 | Software "Config button" | 0 | Not actuated (bus controller default setting) |
| | | 1 | Pressed (necessary so that slaves can also be reconfigured) |
| 4 - 7 | Reserved | 0 | |

9.18.2.8.12 Configure the operating mode of the master

Name:

SmartWireMode

This register can be used to configure the master operating mode.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 1 |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------|-------|--|
| 0 - 1 | Operating mode | 00 | CONFIG from RAM (controller) |
| | | 01 | Read CONFIG from flash memory (bus controller default setting) |
| | | 10 | Write CONFIG to flash |
| | | 11 | Reserved |
| 2 - 7 | Reserved | 0 | |

9.18.2.8.13 Basic application registers "SmartWireEnable" and "SmartWireMode"

By default, the SmartWire bus is started automatically and must at least be configured using an external method (e.g. external button or push-button).

If sensors / actuators are added to or removed from the SmartWire bus, then the configuration procedure must be restarted so that the SmartWire bus will be rescanned and the new configuration saved remanently in the master.

These registers can and must be used for special conditions and for acknowledging errors.

The commands with the library are sent asynchronously on the X2X link network. The following is therefore essential for error-free operation of the module.

- Command register "SmartWireMode" on page 2110 is written to first. Writing to register "SmartWireEnable" on page 2110 is permitted after the function block reports that it is finished.
- The function block status response is checked in the application.
- The specified response from the master status information must arrive in order for the master state machine to function properly

9.18.2.8.13.1 Starting the bus when Manual Start has been configured

Status information after startup:

| Value (decimal) | Register | Information |
|-----------------|----------------------|-------------|
| 1 | MasterOperatingState | Init State |
| 0 | MasterStatus | |
| 0 | SlaveStatus | |

If Manual start is selected for the bus in the configuration, then the AsIOAccWrite() function from the AsIOAcc library must be used to write to the two registers in the specified order.

| Value (decimal) | Register | Information |
|-----------------|-----------------|------------------------------------|
| 1 | SmartWireMode | Configuration from rem. memory |
| 3 | SmartWireEnable | Command for STACK ON / OPERATIONAL |

Status information after error-free startup of the bus:

| Value (decimal) | Register | Information |
|-----------------|----------------------|--|
| 20 | MasterOperatingState | "RUN without error if SlaveStatus = 0" |
| 345 | MasterStatus | "RUN without error if SlaveStatus = 0" |
| 0 | SlaveStatus | No slave errors |

9.18.2.8.13.2 Starting the bus after slave error

Status information after slave error

In this case, a change to MasterOperatingState and MasterStatus cannot be detected at first, although the respective error bits are set in the SlaveStatus. The slaves have failed, and data is no longer being exchanged.

| Value (decimal) | Register | Information |
|-----------------|----------------------|--|
| 20 | MasterOperatingState | |
| 345 | MasterStatus | |
| x | SlaveStatus | Bits for the faulty slaves have been set |

To set the master to a defined state, the bus must first be stopped with the following write commands.

| Value (decimal) | Register | Information |
|-----------------|-----------------|-------------|
| 0 | SmartWireMode | All off |
| 0 | SmartWireEnable | All off |

Wait until the commands have been completed successfully, which is indicated in the MasterStatus. Bit 4 is cleared: Response indicating that the bus is no longer operational.

| Value (decimal) | Register | Information |
|-----------------|----------------------|-------------|
| 20 | MasterOperatingState | |
| 329 | MasterStatus | |
| 0 | SlaveStatus | |

The bus can be restarted using the write commands after the errors have been corrected:

| Value (decimal) | Register | Information |
|-----------------|-----------------|------------------------------------|
| 1 | SmartWireMode | Configuration from rem. memory |
| 3 | SmartWireEnable | Command for STACK ON / OPERATIONAL |

Status information after error-free startup of the bus:

| Value (decimal) | Register | Information |
|-----------------|----------------------|--|
| 20 | MasterOperatingState | "RUN without error if SlaveStatus = 0" |
| 345 | MasterStatus | "RUN without error if SlaveStatus = 0" |
| 0 | SlaveStatus | No slave errors |

Different status information can result depending on the present error situation (see "[MasterOperatingState](#)" on [page 2107](#)).

Typical situation when there are hardware configuration differences:

| Value (decimal) | Register | Information |
|-----------------|----------------------|-------------|
| 0 | MasterOperatingState | |
| 80 | MasterStatus | |
| 0 | SlaveStatus | |

Information:

A stop command must be sent before a new start command can be applied!

9.18.2.8.14 Advanced applications

The following registers are used for advanced diagnostics, for reading back the current configuration and for creating a configuration from the application. The registers that have already been written and their respective contents are, of course, valid.

9.18.2.8.14.1 Status of the individual slaves

Name:

SlaveStatus1 to SlaveStatus16

These registers display the respective slave status.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|-----------------------------|
| 0 | | 0 | Slave integrated on the bus |
| | | 1 | Slave failure on the bus |
| 1 - 7 | Reserved | 0 | |

9.18.2.8.14.2 Read slave vendor ID

Name:

Vendor1 to Vendor16

These registers display the respective slave Vendor ID.

| Data type | Value | Information |
|-----------|-------|-----------------|
| USINT | x | Slave vendor ID |

9.18.2.8.14.3 Read slave device ID

Name:

Device1 to Device16

These registers display the respective slave device ID.

| Data type | Value | Information |
|-----------|-------|-----------------|
| USINT | x | Slave device ID |

9.18.2.8.14.4 Write slave vendor ID

Name:

Vendor1Cfg to Vendor16Cfg

The desired vendor ID for the slave can be written in these registers.

| Data type | Value | Information |
|-----------|-------|--|
| USINT | x | Vendor ID of the slave. Bus controller default setting: 1 |

9.18.2.8.14.5 Write slave device ID

Name:

Device1Cfg to Device16Cfg

The desired device ID for the slave can be written in these registers.

| Data type | Value | Information |
|-----------|-------|---|
| USINT | x | Device ID of the slave. Bus controller default setting: 33 |

Import the configuration without starting the bus

For safety reasons, it is possible to import the configuration for the connected bus without starting cyclic data transfer. This actual configuration can be compared with the set configuration stored in the application. Cyclic data transfer can be started if the configurations are the same. An error is reported if they are not the same.

Manual start is configured, status information after startup:

| Value (decimal) | Register | Information |
|-----------------|----------------------|-------------|
| 1 | MasterOperatingState | Init State |
| 0 | MasterStatus | |
| 0 | SlaveStatus | |

The function AsIOAccWrite() from the library AsIOAcc must be used to write the two registers in the specified order.

| Value (decimal) | Register | Information |
|-----------------|-----------------|---|
| 0 | SmartWireMode | RAM memory configuration |
| 9 | SmartWireEnable | Command for STACK ON / PREOPERATIONAL and CONFIG-BUTTON |

Status information after error-free import of the bus configuration:

| Value (decimal) | Register | Information |
|-----------------|----------------------|--|
| 20 | MasterOperatingState | "RUN without error if SlaveStatus = 0" |
| 1349 | MasterStatus | "PREOP and no errors" |
| 0 | SlaveStatus | No slave errors |

Once these commands have been completed, the connected slave modules are imported and stored in the remanent memory for subsequent startups.

The function AsIOAccRead() from the library AsIOAcc must now be used to read all corresponding registers "Vendor1 to Vendor16" on page 2113 and "Device1 to Device 16" on page 2113 . If the configuration matches, then the bus can now be started using the standard command:

| Value (decimal) | Register | Information |
|-----------------|-----------------|------------------------------------|
| 1 | SmartWireMode | Configuration from rem. memory |
| 3 | SmartWireEnable | Command for STACK ON / OPERATIONAL |

Status information after error-free startup of the bus:

| Value (decimal) | Register | Information |
|-----------------|----------------------|--|
| 20 | MasterOperatingState | "RUN without error if SlaveStatus = 0" |
| 345 | MasterStatus | "RUN without error if SlaveStatus = 0" |
| 0 | SlaveStatus | No slave errors |

Bus configuration settings

Manual start is configured, status information after startup:

| Value (decimal) | Register | Information |
|-----------------|--------------------------------------|-------------|
| 1 | MasterOperatingState | Init State |
| 0 | MasterStatus | |
| 0 | SlaveStatus | |

A running bus can, of course, also be stopped with the standard command and re-configured!

The function `AsIOAccWrite()` from the library `AsIOAcc` must now be used to write the respective data to all registers "[Vendor1Cfg to Vendor16Cfg](#)" on page 2113 and "[Device1Cfg to Device16Cfg](#)" on page 2113. All vendor and device registers that are not being used must be set to zero. This does not cause a change in the status registers.

To save the data in remanent memory, the function `AsIOAccWrite()` from the library `AsIOAcc` must be used to write to the two registers in the specified order.

| Value (decimal) | Register | Information |
|-----------------|---------------------------------|------------------------------------|
| 2 | SmartWireMode | WRITE rem. memory configuration |
| 1 | SmartWireEnable | Command for STACK ON / OPERATIONAL |

Status information after error-free configuration:

| Value (decimal) | Register | Information |
|-----------------|--------------------------------------|--|
| 20 | MasterOperatingState | "RUN without error if SlaveStatus = 0" |
| 325 | MasterStatus | "PREOP without errors" |
| 0 | SlaveStatus | No slave errors |

The bus can now be started using the standard command for the bus:

| Value (decimal) | Register | Information |
|-----------------|---------------------------------|------------------------------------|
| 1 | SmartWireMode | Configuration from rem. memory |
| 3 | SmartWireEnable | Command for STACK ON / OPERATIONAL |

Status information after error-free startup of the bus:

| Value (decimal) | Register | Information |
|-----------------|--------------------------------------|--|
| 20 | MasterOperatingState | "RUN without error if SlaveStatus = 0" |
| 345 | MasterStatus | "RUN without error if SlaveStatus = 0" |
| 0 | SlaveStatus | No slave errors |

9.18.2.8.15 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.18.3 X20CS1012

Data sheet version: 1.19

9.18.3.1 General information

The M-Bus master is designed as a single-width module and can be connected anywhere within the X20 I/O system. It can therefore be used decentrally for distributed topologies. The M-Bus master supports transfer rates of 300, 2400 and 9600 bit/s; up to 64 slaves supplied via M-Bus can be connected.

M-Bus (Meter-Bus) is a relatively simple fieldbus for recording consumption data, such as from electricity or heat meters. It is based on a reverse polarity protected two-wire line and works according to the master-slave principle.

- Power supply for up to 64 slaves on the M-Bus
- Decentralized use of the communication interface

9.18.3.2 Order data

| Model number | Short description | Figure |
|--------------|---|--|
| | X20 electronics module communication |  |
| X20CS1012 | X20 interface module, 1 M-Bus master interface, integrated slave supply | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |
| | | |
| | | |

Table 383: X20CS1012 - Technical data

1) Dependent on the changes to the load on the M-Bus (e.g. switching slaves on and off)

9.18.3.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

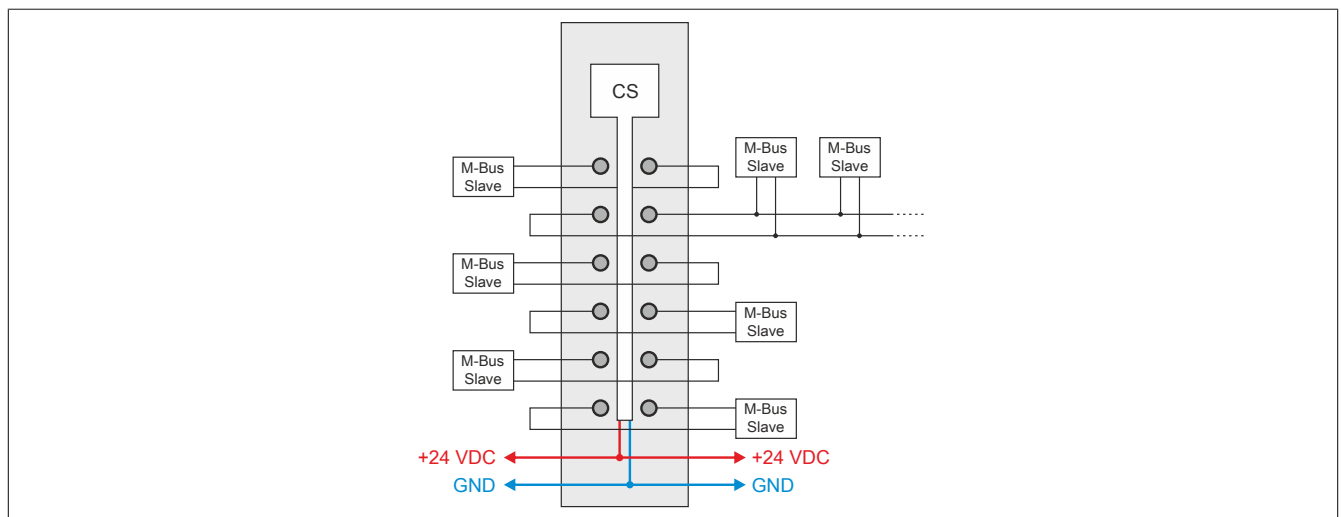

| Figure | LED | Color | Status | Description |
|---|-------|-----------------------------|--------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | UNLINK mode |
| | | | Double flash | Mode BOOT (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | e + r | Red on / Green single flash | | Invalid firmware |
| | S | Yellow | Off | No slaves sending data |
| | | | On | At least one slave is sending data via the M-Bus |
| | P | Red | Off | M-Bus supply ok |
| | | | On | Short-circuit or overload on M-Bus |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.18.3.5 Pinout

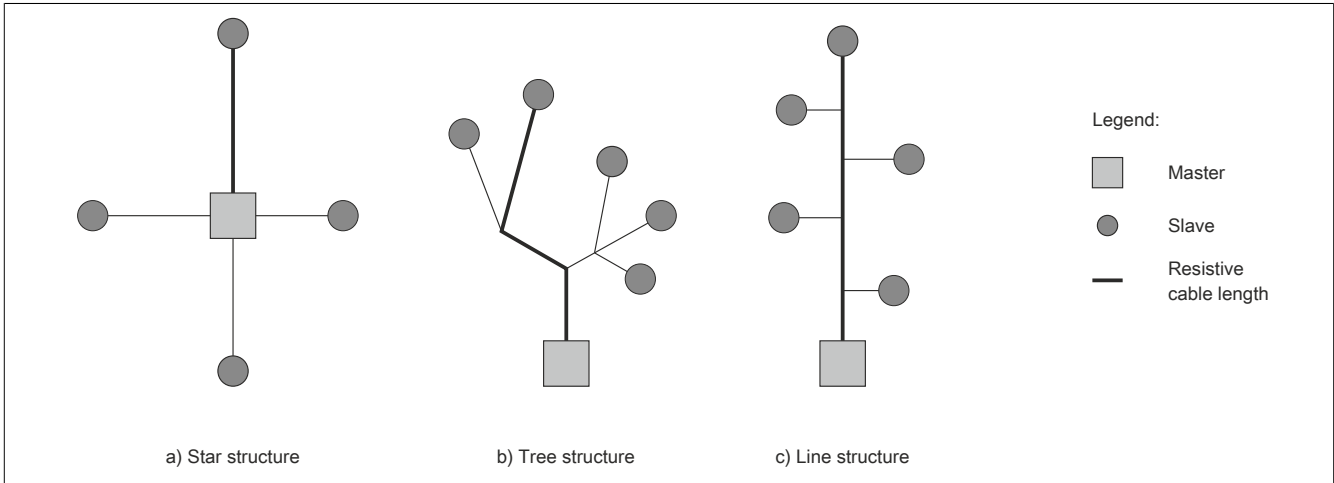

9.18.3.6 Connection example

9.18.3.7 M-Bus

9.18.3.7.1 Bus topology

The bus topology has a significant influence on the maximum load of an M-Bus network. In general a star structure is preferred over a tree structure and in turn a tree structure is preferred over a line structure. Furthermore, connecting the slaves to the bus the same way provides better values than connecting them all at the end of the branches after all other parameters have been determined.

9.18.3.7.2 Cable cross section

The cable being used has a specific capacity and resistance, which in turn has an effect on the operation of the bus. The resistive influence of the cable means a loss of voltage on the line, which is subsequently not available for supplying the bus. In order to guarantee sufficient power, the voltage on the slaves must never be less than 12 V neither when sending from the master to the slave, nor in the opposite direction. The deciding factor in this case is the longest branch of the network whose length is referred to as the resistive cable length.

The cable's capacity causes signal distortion during data transfer because the slew rates of the rising and falling edges are slowed down. For example, replacing a 3 km branch in a network with two 1.5 km branches will improve the signal. The total distance of the network is referred to as the capacitive cable length (the sum of all segment lengths).

Information:

The maximum permissible line resistance (for the longest loop) is 250 Ω .

The maximum permissible line capacitance for the entire bus is 500 nF.

9.18.3.7.3 Transmission current and bit threshold

The bit threshold on the master is typically 7.5 mA. Therefore, a slave transmission current of 15 mA results in the least amount of signal distortion while the highest amount occurs at 11 or 20 mA.

9.18.3.7.4 Transfer rate

A lower transfer rate decreases the influence of the signal distortion caused by cable capacity and bit threshold.

Information:

Starting with a total bus length >1 km, the slaves must be operated at a baud rate <9600 bit/s.

9.18.3.7.5 Calculating the resistive bus length

The resistive cable length must be calculated in order to ensure a sufficient power supply of 12 V on the M-Bus. What matters most here is the longest segment between the master and slave.

The resistive bus length is calculated using the following formula without taking an increased bus current caused by a defective receiver into account:

$$L_{\text{res}} = \frac{V_{\text{I/O}} - (n * 0.0015 + 0.02) * 6 - 12.6}{(n * 0.0015 + 0.02) * R_L} * 1000$$

- L_{res} ... Resistive bus length [m]
 n ... Number of slaves (all at end of line)
 R_L ... Line resistance (loop resistance [Ω /km])
 $V_{\text{I/O}}$... I/O supply voltage [V]

Examples for calculating the maximum resistive bus length:

| No. | Example | Maximum resistive bus length |
|-----|--|------------------------------|
| 1 | <ul style="list-style-type: none"> 64 slaves (all at end of line) 19.2 V I/O supply voltage 0.5 mm² wire cross-section | 675 m |
| 2 | <ul style="list-style-type: none"> 64 slaves (all at end of line) 28.8 V I/O supply voltage 1.5 mm² wire cross-section | 5340 m |

9.18.3.7.6 Accounting for the capacitive bus length

The total distance of the network is referred to as the capacitive bus length (the sum of all segment lengths). The capacitive bus length depends on two factors:

- Distributed capacitance of cable
- Transfer rate

Distributed capacitance of cable

A lower distributed capacitance on a cable means a higher capacitive bus length.

Transfer rate

A lower transfer rate on an M-Bus system means a higher capacitive bus length.

Example of a cable with a distributed capacitance of 50 nF/km:

| Transfer rate | Capacitive bus length |
|---------------|-----------------------|
| 9600 bit/s | 1 km |
| 2400 bit/s | 4 km |
| 300 bit/s | 10 km |

9.18.3.7.7 Bus installation

Cables with twisted pair wires and a cross-section of 0.5 mm² to 1.5 mm² are normally used for bus installation (according to standard: J-Y(ST)Y nx2x0.8). The shield on shielded cables only has to be grounded to the module on one side. On the slaves, the shielding must be high resistance for DC and low frequency signals.

9.18.3.7.8 Repeater

Repeaters can be used to further expand the M-Bus network.

9.18.3.8 Register description

9.18.3.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.18.3.8.2 Function model 0 - Standard

| Register | Name | Data type | Read | | Write | |

1) The offset specifies the position of the register within the CAN object.

9.18.3.8.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "[Using I/O modules on the bus controller](#)" on page 3789.

9.18.3.8.3.2 CAN I/O bus controller

The module occupies 3 analog logical slots with CAN I/O.

9.18.3.8.4 General information

The M-Bus standard is a serial bus system that handles half-duplex or asynchronous communication. The high level of variability provided by this protocol enables a wide range of information to be handled via the same interface. In basic M-Bus networks, the master communicates with up to 250 slaves via the "primary address". In later stages of development, the secondary address (4 bytes) was then also specified. This made it possible to significantly increase the number of slaves in a network.

Important information about the module

- Generally: Primary address used (1 to 250)
- Secondary address only supported via FlatStream
- Bus can supply 64 slaves with power

9.18.3.8.5 Module configuration

The flexible design of the M-Bus protocol can quickly add up to a lot of configuration work. That's why B&R offers two different user interfaces for the module: "Standard" and "FlatStream". The user-friendly B&R Standard interface allows users to view up to eight values requested cyclically from the M-Bus network. In FlatStream mode, the module acts as a bridge between the PLC and the M-Bus slave, which makes all M-Bus functions available.

Information:

The B&R Standard interface is statically configured and based on cyclic registers. Because X2X Link can only transfer a certain number of values cyclically, the user must make his selection accordingly.

9.18.3.8.5.1 Settings for operation

Name:

CfO_FunctionModel

This register can be used to enable either the Standard or FlatStream interface, which makes the module much more efficient.

Bits 8 to 15 are only evaluated if bit 0 (B&R default interface) is enabled.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 1825 |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|-------|---|
| 0 | B&R standard interface | 0 | Disabled |
| | | 1 | Enabled (bus controller default setting) |
| 1 | Flatstream | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 3 - 7 | Reserved | 0 | |
| 8 | Data1 | 0 | Disabled |
| | | 1 | Enabled (bus controller default setting) |
| ... | | ... | |
| 10 | Data 3 | 0 | Disabled |
| | | 1 | Enabled (bus controller default setting) |
| 11 | Data 4 | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| ... | | ... | |
| 15 | Data8 | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |

9.18.3.8.6 M-Bus - Configuration

Separate configuration registers are provided for each value to read. These must be configured correctly in order to call up a counter value from the M-Bus network. The user must know the following values from the slave:

- Transfer rate configured on the slave
- Primary address configured on the slave (value: 1 to 250, otherwise only point-to-point connection is possible)
- Data type / data length of value
- How the slave's memory is structured

Information:

The following section "M-Bus - Configuration" is based solely on the B&R standard interface.

9.18.3.8.6.1 Data length

Name:

CfO_LengthData1 to CfO_LengthData8

The Standard interface is able to request data from the M-Bus slave with different lengths. When using Automation Studio the value of the "Length" register is a result of the data type defined for the X2X Link. All common data types with up to 4 bytes in length are supported.

| Data type | Value | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 8 |

Bit structure:

| Bit | Name | Value | Information |
|-------|------------------|---------|--|
| 0 - 5 | Data length code | 00 0000 | USINT |
| | | 00 0001 | SINT |
| | | 00 0010 | UINT |
| | | 00 0100 | INT |
| | | 00 1000 | UDINT (bus controller default setting) |
| | | 01 0000 | DINT |
| | | 10 0000 | REAL |
| 6 - 7 | Reserved | 0 | |

9.18.3.8.6.2 Transfer rate

Name:

CfO_BaudData1 to CfO_BaudData8

This register can be used to define the transfer rate for retrieving the desired values.

| Data type | Value | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 4 |

Bit structure:

| Bit | Name | Value | Information |
|-------|------------------|-------|--|
| 0 - 3 | Baud rate (Code) | 0000 | Reserved! |
| | | 0001 | 300 bit/s |
| | | 0010 | 600 bit/s |
| | | 0011 | 1200 bit/s |
| | | 0100 | 2400 bits/s (bus controller default setting) |
| | | 0101 | 4800 bit/s |
| | | 0110 | 9600 bit/s |
| | | 0111 | 19200 bit/s |
| | | 1000 | 38400 bit/s |
| 4 - 7 | Reserved | 0 | |

9.18.3.8.6.3 Address

Name:

CfO_PAdrData1 to CfO_PAdrData8

This register can be used to define the address where the desired values will be requested from.

| Data type | Value | Information |
|-----------|----------|-------------------------------------|
| USINT | 1 to 250 | Bus controller default setting: 254 |

Special addresses:

| Value | Information |
|------------|--|
| 251 to 253 | Reserved (in accordance with M-Bus specification) |
| 254 | Broadcast address (response from all connected slaves - risk of collision) |

9.18.3.8.6.4 Index

Name:

CfO_IndexData1 to CfO_IndexData8

This register is used to specify the ordinal number of the value (independent of the medium). This value results from the order of values in the slave. The value is then transferred to the data register.

| Data type | Value | Information |
|-----------|----------|-----------------------------------|
| USINT | 1 to 255 | Bus controller default setting: 1 |

9.18.3.8.6.5 Specifies the refresh time

Name:

CfO_ReqTimeData1 to CfO_ReqTimeData8

The slave information can be queried manually or time-based. A time-controlled query must include the value for the refresh time. The associated unit is defined in register "M-Bus mode" on page 2125.

| Data type | Value | Information |
|-----------|----------|---|
| USINT | 1 to 255 | In [s, min]. Bus controller default setting: 0 |

9.18.3.8.6.6 M-Bus mode

Name:

CfO_MBusModeData1 to CfO_MBusModeData8

To speed up the module's boot procedure, various configuration details that define the module's behavior have been combined in this register.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 2 |

Bit structure:

| Bit | Description | Value | Information |
|---------|-----------------------------|-------|---|
| 0 - 2 | Byte offset | 0 - 7 | Data types. Bus controller default setting: 2 |
| 3 - 4 | Reserved | 0 | |
| 5 | InitFrame | 0 | No additional frame (bus controller default setting) |
| | | 1 | Transmit additional frame |
| 6 | ApplicationResetFrame | 0 | No additional frame (bus controller default setting) |
| | | 1 | Transmit additional frame |
| 7 | Replacement value strategy | 0 | Hold last valid value (bus controller default setting) |
| | | 1 | Replace with static value |
| 8 | Time-based reading | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 9 | Manually triggered reading | 0 | Disabled (bus controller default setting) |
| | | 1 | Reading via register " MBusCommand " on page 2127 |
| 10 | Unit of periodic reading | 0 | [s] - Seconds (bus controller default setting) |
| | | 1 | [min] - Minutes |
| 11 - 15 | Reserved | 0 | |

Byte offset

The M-Bus specification allows for many individual data types. In order to also read these counter values with up to 64 bits, a slave value may have to be read using 2 data registers. The byte offset can be defined to select a desired section of the information.

9.18.3.8.6.7 Timeout offset

Name:

CfO_ToutOffData1 to CfO_ToutOffData8

The timeout for the M-Bus communication generally depends on the currently defined transfer rate. The user can also define an offset value in addition to the calculated standard timeout.

Timeout = standard timeout + (timeout offset * 10 ms)

| Data type | Value | Information |
|-----------|----------|--|
| USINT | 0 to 255 | Resolution 10 ms. Bus controller default setting: 0 |

9.18.3.8.6.8 Static replacement value

Name:

CfO_ReplData1 to CfO_ReplData8

This register defines the static replacement value if replacement value strategy "Replace with static value" was enabled in register "[CfO_MBusModeData](#)" on [page 2125](#). The data register takes on this value if an invalid input value is detected.

| Data type | Value | Information |
|--------------------------------------|------------------------|-----------------------------------|
| (U)SINT (U)INT (U)DINT REAL | According to data type | Bus controller default setting: 0 |

9.18.3.8.7 M-Bus - Communication

Three important control and status bytes are provided in the B&R interface for communication with the M-Bus slaves. Register "MBusCommand" on page 2127 switches UART on/off, for example, in order to increase the system's energy efficiency.

Up to 8 cyclic input registers are registered depending on the configuration. Manually configured data must be requested via register "MBusCommand" on page 2127. Registers "ValidDataByte" on page 2128 and "InvalidDataByte" on page 2128 can be used to determine the quality of the value currently read.

Information:

The following section "M-Bus - Communication" is based solely on the B&R standard interface.

9.18.3.8.7.1 M-Bus commands

Name:

MBusCommand

This register can be used to apply different commands to the module. The module only responds to positive edges.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|--------------------------------------|-------|-----------------|
| 0 | Activate UART | 0 → 1 | Execute command |
| 1 | Read manually triggered values | 0 → 1 | Execute command |
| 2 | Acknowledge the "MBusState" register | 0 → 1 | Execute command |
| 3 - 6 | Reserved | 0 | |
| 7 | Deactivate UART | 0 → 1 | Execute command |

Bit 0 and 7

The level converter is switched on by default when the module boots. This bit can be used to switch it on or off from the application to save electricity, for example.

9.18.3.8.7.2 M-Bus operation

Name:

MBusOperation

This register shows the user which task the module is currently processing. The LSB is always set when the UART is active. Manual commands are indicated by an increase of one in this byte while being processed.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|--|-------|---------------------------------------|
| 0 | UART | 0 | Inactive |
| | | 1 | Active |
| 1 | Read values | 0 | - |
| | | 1 | Command being processed |
| 2 | Refresh/reset the "MBusState" register | 0 | - |
| | | 1 | Command being processed ¹⁾ |
| 3 - 6 | Reserved | 0 | |
| 7 | UART | 0 | Inactive |
| | | 1 | Active |

1) Bit 2 is only set for one X2X cycle. Requesting this bit is not recommended when operating the module behind a bus controller.

9.18.3.8.7.3 M-Bus state

Name:
MBusState

This register contains the current M-Bus network error state. All bits are managed in nonvolatile memory. This means they must be reset via register "MBusCommand" on page 2127.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|--|-------|---|
| 0 | Collision detection | 0 | Error-free addressing |
| | | 1 | Multiple addresses on the bus |
| 1 | Read error (at least once) | 0 | Configured information OK |
| | | 1 | Could not read information |
| 2 | Checksum | 0 | Received checksum OK |
| | | 1 | Error in input direction |
| 3 | M-Bus load | 0 | Power supply OK |
| | | 1 | Load too high on M-Bus network |
| 4 | Communication aborted due to overflow | 0 | Everything OK |
| | | 1 | The master is overloaded and cannot take on any additional requests. Corrective measure: Repeat the request. ¹⁾ |
| 5 | Communication aborted due to level converter | 0 | Everything OK |
| | | 1 | Level converter is OFF (aborted at runtime or not started). |
| 6 | Data exchange since startup | 0 | Valid data not yet received |
| | | 1 | Valid data at least once |
| 7 | UART off MBUS ENABLE | 0 | M-Bus driver, level converter inactive |
| | | 1 | Module ready for communication |

1) Communication is reestablished automatically as soon as the pending communication jobs have been processed.

9.18.3.8.7.4 Valid data

Name:
ValidDataByte

ValidData1 to ValidData8

This register indicates (by bit) which of the max. 8 read values are valid.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|------------|-------|-----------------|
| 0 | ValidData1 | 0 | Value 1 invalid |
| | | 1 | Value 1 valid |
| ... | ... | ... | ... |
| 7 | ValidData8 | 0 | Value 8 invalid |
| | | 1 | Value 8 valid |

9.18.3.8.7.5 Invalid data

Name:
InvalidDataByte

InvalidData1 to InvalidData8

The validity of the read values can be checked redundantly. This register indicates (by bit) which of the max. 8 read values are invalid.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|--------------|-------|-----------------|
| 0 | InvalidData1 | 0 | Value 1 valid |
| | | 1 | Value 1 invalid |
| ... | ... | ... | ... |
| 7 | InvalidData8 | 0 | Value 8 valid |
| | | 1 | Value 8 invalid |

9.18.3.8.7.6 Data

Name:

Data1 to Data8

Each cyclic data register contains the respective pre-configured value from the M-Bus network. The data type of the data register was designed to be variable and must be specified by the user during configuration.

Information:

Because X2X Link can only transfer a certain number of bytes cyclically, the user must make his selection accordingly.

| Data type | Value |
|--------------------------------------|------------------------|
| (U)SINT (U)INT (U)DINT REAL | According to data type |

9.18.3.8.7.7 Change the serial number of an M-bus slave

Name:

ChangedSNByte

This register indicates (by bit) whether one of the M-Bus slave serial numbers on the bus has changed. Only the serial numbers of the slaves accessed via the B&R interface are checked. The respective bit is toggled if a change is detected.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-----|--------------|--------|-------------------------------|
| 0 | SN (Slave 1) | 0 -> 1 | Slave1: Serial number changed |
| | | 1 -> 0 | |
| ... | ... | ... | ... |
| 7 | SN (Slave 8) | 0 -> 1 | Slave8: Serial number changed |
| | | 1 -> 0 | |

9.18.3.8.7.8 M-Bus slave serial numbers

Name:

SNDData1 to SNDData8

These registers contain the serial numbers of the M-Bus slaves that are queried via the B&R interface. They are implemented acyclically and can be read using library AsIOAcc.

| Data type | Values |
|-----------|--------------------|
| UDINT | 0 to 4,294,967,295 |

9.18.3.8.8 Flatstream communication

For a description of Flatstream communication, see ["Flatstream communication" on page 3802](#)

9.18.3.8.9 M-Bus with FlatStream

When using FlatStream communication, the module acts as a bridge between the X2X master and an intelligent field device connected to the module. FlatStream mode can be used for either point-to-point connections as well as for bus systems. Specific algorithms such as timeout and checksum monitoring are usually managed automatically. During normal operation, the user does not have direct access to these details.

Operation

The M-Bus specification recognizes four different frame types. From the application standpoint, only "long frames" are generated and transferred when using the M-Bus via FlatStreams. Due to the flexible design of the M-Bus protocol, the user must include the corresponding slave configuration with each request.

| FlatStream structure | | |
|-----------------------------------|-----------------------------|---|
| In-/OutputSequence (unchanged) | Control byte (unchanged) | Rx-/TxBytes M-Bus data (FlatStream) |

9.18.3.8.9.1 FlatStream in output direction

FlatStream query

This standard protocol specifies that a data query via FlatStream consists of a main part and two index records. An index record is made up of an introduction containing various information and followed by a parameter block.

Introduction

The primary role of the main part is to assign a synchronization number and register the protocol type.

Note 1

When registering an undefined protocol type, the module works with the standard protocol.

Note 2

Because there is currently only one protocol type defined, the corresponding configuration bytes should be set to 1. This will allow the protocol to be expanded later without becoming incompatible with existing projects.

| Bytes | Name | Value | Description |
|-------|--|---------|---|
| 1 | Frame number: For synchronization in the application | 0 - 255 | The frame number is repeated in the module's response. This allows the later response from the module to be distinctly attributed to the request. |
| 2 | Index Record Count "i" | 2! | Number of subsequent index records |
| 3 | Protocol type | 0 | Native M-Bus (level converter mode) - see "Native M-Bus" |
| | | 1 | Data query (raw data / parameters) |
| 4 | Reserved | 1! | |
| ... | Index record (configuration) | | |
| ... | Index record (data query) | | |

Native M-Bus

The "Native M-Bus" protocol type provides universal communication within the M-Bus network. It can be used to assemble and send M-Bus frames in the application.

A conventional data query is possible using a raw data or parameter query.

Index record 0

Configuration block

The interface parameters for defining the module's behavior in the M-Bus network must be chosen configuration part.

Information:

With the standard protocol, the index record must be resent with each request for configuration.

Introduction

| Bytes | Name | Value | Description |
|-------|----------------------------------|-------|---------------------------------------|
| 1 | Index record type | 0! | Module interface configuration |
| 2 | Counter (config parameter) | 5! | Number of subsequent M-Bus parameters |
| 3 | Length of parameter block - Low | 19! | Length of index record description |
| 4 | Length of parameter block - High | 0! | Length of index record description |

Parameter block

Configuration parameter 0 - Addressing type

| Bytes | Name | Value | Description |
|-------|------------------|-------|----------------------------------|
| 1 | Parameter number | 0! | |
| 2 | Length | 1! | |
| 3 | Addressing type | 1 | Addressing via primary address |
| | | 2 | Addressing via secondary address |

Configuration parameter 1 - Address

| Bytes | Name | Value | Description |
|-------|--------------------|---------|---------------------------|
| 4 | Parameter number | 1! | |
| 5 | Length | 4! | |
| 6 | Address - LowLow | 1 - 255 | Primary address |
| 7 | Address - LowHigh | 0 - 255 | 0!, if primary addressing |
| 8 | Address - HighLow | 0 - 255 | 0!, if primary addressing |
| 9 | Address - HighHigh | 0 - 255 | 0!, if primary addressing |

Configuration parameter 2 - Transfer rate

| Bytes | Name | Value | Description |
|-------|--------------------|---------|-----------------------------------|
| 10 | Parameter number | 2! | |
| 11 | Length | 2! | |
| 12 | Transfer rate Low | 0 - 255 | Verified transfer rates |
| 13 | Transfer rate High | 0 - 255 | 300 bit/s, 2400 bit/s, 9600 bit/s |

Configuration parameter 3 - Timeout offset

| Bytes | Name | Value | Description |
|-------|------------------|---------|---|
| 14 | Parameter number | 3! | |
| 15 | Length | 1! | |
| 16 | TimeoutOffset | 0 - 255 | Additional time for timeout monitoring on the M-Bus (Resolution: 10 ms) |

Configuration parameter 4 - Extra frames

| Bytes | Name | Value | Description |
|-------|------------------|-------------|-----------------------------------|
| 17 | Parameter number | 4! | |
| 18 | Length | 1! | |
| 19 | M-Bus options | Bit 0 ... 1 | Send Init frame |
| | | Bit 1 ... 1 | Send application reset |
| | | Bit 6 ... 1 | Set frame count bit ¹⁾ |
| | | Bit 7 ... 1 | Request media and version |

1) Some M-Bus slaves use this bit to switch to a another data set.

Index record 1

Data query block

The M-Bus parameters to be retrieved from the memory of the M-Bus slaves are requested in the request part. The user can request certain parameters from the slave or the entire slave memory.

Introduction

| Bytes | Name | Value | Description |
|-------|---|---------|---|
| 1 | Index record type | 1! | Data request for M-Bus slave |
| 2 | Counter (data parameter) = (d + 1) | 0 | <ul style="list-style-type: none"> Communication via native M-Bus Read out M-Bus raw data |
| | | 1 - 20 | Number of parameters to read out |
| 3 | Length of subsequent block - Low | 0 - 255 | <ul style="list-style-type: none"> Length of M-Bus frame to be sent Length of parameter block 0! with raw data query |
| 4 | Length of subsequent block - High | 0 - 255 | <ul style="list-style-type: none"> Length of M-Bus frame to be sent Length of parameter block 0! with raw data query |
| ... | Depending on request: <ul style="list-style-type: none"> Native M-Bus frame Parameter block | | <i>Not needed if raw data query = 0</i> |

M-Bus frame

M-Bus frame to be sent

| Bytes | Name | Value | Description |
|-------|----------|---------|----------------------------|
| 1 | TxByte 1 | 0 - 255 | Byte 1 in output direction |
| 2 | TxByte 2 | 0 - 255 | Byte 2 in output direction |
| n | TxByte n | 0 - 255 | Byte n in output direction |

Parameter block

Data parameter 0

| Bytes | Name | Value | Description |
|-------|------------------|--------|-------------------------------|
| 1 | Parameter number | 0! | |
| 2 | Data index | 1 - 48 | Data index in the M-Bus frame |

Data parameter 1

| Bytes | Name | Value | Description |
|-------|------------------|--------|-------------------------------|
| 2 | Parameter number | 1! | |
| 3 | Data index | 1 - 48 | Data index in the M-Bus frame |

Data parameter d

| Bytes | Name | Value | Description |
|-------|------------------|--------|-------------------------------|
| ... | Parameter number | d! | |
| ... | Data index | 1 - 48 | Data index in the M-Bus frame |

9.18.3.8.9.2 FlatStream in input direction

FlatStream response

The standard protocol has three different responses according to the request.

Error response

The error response occurs when the module receives an invalid or incomplete request.

| Byte | Name | Value | Description |
|------|--|---------|---|
| 1 | Frame number: For synchronization in the application | 0 - 255 | This frame number is repeated in the module's response. In this way, the response of the module can be clearly assigned to the request. |
| 2 | Error code - LowLow | 0 - 255 | See the error code table. |
| 3 | Error code - LowHigh | 0 - 255 | See the error code table. |
| 4 | Error code - HighLow | 0 - 255 | See the error code table. |
| 5 | Error code - HighHigh | 0 - 255 | See the error code table. |
| 6 | Additional information - LowLow | 0 - 255 | Optional |
| 7 | Additional information - LowHigh | 0 - 255 | Optional |
| 8 | Additional information - HighLow | 0 - 255 | Optional |
| 9 | Additional information - HighHigh | 0 - 255 | Optional |

Error codes

| Error code and name | Error description |
|---------------------|--|
| 0x11111111 | An M-Bus counter is not responding to a data request. This can have different causes: <ul style="list-style-type: none"> The counter is not connected. The counter is defective. A counter with the selected addressing parameters does not exist on the bus. |
| 0x22222222 | This error code is transmitted if addressing via the secondary address and the selected counter does not respond. |
| 0x33333333 | If an invalid transfer rate is sent along with the stream, it is not evaluated. No M-Bus frame is sent; the Flatstream interface responds directly with this error code. |
| 0x44444444 | If a collision occurs on the bus while querying the data, the data request is ended and this error code is returned. |
| 0x55555555 | Communication aborted due to overflow (see bit 4 in section "M-Bus state" on page 2128) |
| 0x66666666 | Before the data is evaluated by the M-Bus counter, the checksum of the M-Bus frame is checked. If this is not correct, the received data is not processed further; instead, the error code is transmitted to the CPU. |
| 0x77777777 | The stream (CPU → IOM) is not correct. It is possible that a parameter number is not correct. The stream is checked very carefully, so an incorrect stream is never used. |
| 0x88888888 | Overload during M-Bus communication |
| 0x99999999 | Communication aborted due to level converter (see bit 5 in section "M-Bus state" on page 2128) |
| 0xA8AAAAAA | Interpretation of slave data not possible. The M-Bus slave being used is not compatible with the parameter query. The M-Bus slave must be implemented using the native M-Bus protocol or a raw data query. |

Additional information

| Additional information | Error description |
|------------------------|---|
| 0x00000001 | Number of index records less than 2 |
| 0x00000002 | Invalid stream length |
| 0x00000004 | Invalid index numbers |
| 0x00000008 | Incorrect number of parameters per index record |
| 0x00000010 | Index length too small |
| 0x00000020 | Incorrect parameter number for index record 0 |
| 0x00000040 | Incorrect parameter length for index record 0 |
| 0x00000080 | Invalid addressing type |
| 0x00000100 | Invalid address |
| 0x00000200 | Invalid transfer rate |
| 0x00000400 | Invalid timeout offset |
| 0x00000800 | Invalid additional frame configuration |

Response - native M-Bus

This response corresponds with a successfully transferred M-Bus frame created within the application.

| Bytes | Name | Value | Description |
|-------|--|---------|---|
| 1 | Frame number: For synchronization in the application | 0 - 255 | The frame number is repeated in the module's response. This allows the response from the module to be distinctly attributed to the request. |
| 2 | Reserved | 0 | |
| ... | Response | | |

Response

| Bytes | Name | Value | Description |
|-------|----------|---------|---------------------------|
| 1 | RxByte 1 | 0 - 255 | Byte 1 in input direction |
| 2 | RxByte 2 | 0 - 255 | Byte 2 in input direction |
| n | RxByte n | 0 - 255 | Byte n in input direction |

Response - Raw data

The raw data response is sent if the M-Bus slave's entire memory is requested.

| Bytes | Name | Value | Description |
|-------|--|---------|---|
| 1 | Frame number: For synchronization in the application | 0 - 255 | The frame number is repeated in the module's response. This allows the response from the module to be distinctly attributed to the request. |
| 2 | M-Bus status | 0 - 255 | Status info from M-Bus header |
| 3 | Raw data frame | 0 - 255 | Includes all bytes sent by the M-Bus slave. |
| ... | | 0 - 255 | |

Response - Parameters

The parameter response is sent if one or more parameters from an M-Bus slave have been requested.

| Bytes | Name | Value | Description |
|-------|--|---------|---|
| 1 | Frame number: For synchronization in the application | 0 - 255 | The frame number is repeated in the module's response. This allows the response from the module to be distinctly attributed to the request. |
| 2 | M-Bus status | 0 - 255 | Status info from M-Bus header |
| 3 | Parameter count "p" | 0 - 255 | Number of parameters received |
| 4 | M-Bus address | 0 - 255 | Primary address |
| 5 | Serial number - LowLow | 0 - 255 | Secondary address |
| 6 | Serial number - LowHigh | 0 - 255 | Secondary address |
| 7 | Serial number - HighLow | 0 - 255 | Secondary address |
| 8 | Serial number - HighHigh | 0 - 255 | Secondary address |
| 9 | VendorID – Low \ Version | 0 - 255 | See "M-Bus option (IndexRecord 0)" on page 2131 |
| 10 | VendorID – High \ Medium | 0 - 255 | See "M-Bus option (IndexRecord 0)" on page 2131 |
| 11 | Data structure (M-Bus) | 1 | Fixed data structure |
| | | 2 | Variable data structure |
| ... | Received parameter 1 through p | | <i>Not needed if parameter count = 0</i> |

Received parameter

| Bytes | Name | Value | Description |
|-------|---------------|---------|------------------------------------|
| 1 | Medium | 0 - 255 | Medium of subsequent counter value |
| 2 | Index | 0 - 255 | Index of subsequent counter value |
| 3 | Data length | 1 - 8 | Length of the counter value |
| | | 255 | If the parameter number is invalid |
| 4 | DIF | 0 - 255 | 0!, if fixed data structure |
| 5 | VIF | 0 - 255 | 0!, if fixed data structure |
| 6 | Counter value | 0 - 255 | LowLowLowLowLowLowLowLow |
| ... | | ... | ... |
| 13 | | 0 - 255 | HighHighHighHighHighHighHighHigh |

9.18.3.8.10 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.18.3.8.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

| Minimum I/O update time |
|-------------------------|
| 1 s |

9.18.4 X20CS1013

Data sheet version: 1.25

9.18.4.1 General information

The module is a DALI control device with an integrated power supply. Up to 64 operating devices can be connected. DALI stands for Digital Addressable Lighting Interface and enables easy and safe control of light fixtures using a standardized digital operating device interface. The DALI bus conforms with EN 62386 series of standards and is now supported by many electronic ballast manufacturers.

- Integrated power supply
- Up to 64 operating devices (individual addresses)
- Up to 16 groups (group addresses)
- Up to 16 scenes (scene lighting values)

9.18.4.2 Order data

| Model number | Short description | Figure |
|--------------|---|--|
| | X20 electronics module communication |  |
| X20CS1013 | X20 interface module, 1 DALI master interface | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |

Table 385: X20CS1013 - Technical data

9.18.4.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-----|--------|---|--|
|  | r | Green | Off | No power to module |
| | | | On | RUN mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error status |
| | Tx | Yellow | | Control device (master) transmitting |
| | Rx | Yellow | | Operating device (slave) responding |
| O | Red | | Error status: Overload or short circuit | |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.18.4.5 Pinout

9.18.4.6 Using an external power supply

Since the internal DALI power supply provides sufficient power for a configuration with up to 64 slaves, the module is not designed for an external power supply.

Warning!

Using an additional DALI power supply may result in damage to the module.

9.18.4.7 Register description

9.18.4.7.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.18.4.7.2 Function model 0 - default

| Register | Name | Data type | Read | | Write | |
|----------|-------------------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 258 | Dali_State | UINT | • | | | |
| 263 | Dali_RequestCounter | USINT | • | | | |
| 261 | Dali_AnswerCounter | USINT | • | | | |
| 265 | Dali_Answer | USINT | • | | | |
| 257 | Dali_Enable | USINT | | | • | |
| 262 | Dali_Control | UINT | | | • | |
| 265 | Dali_Address | USINT | | | • | |
| 267 | Dali_Command | USINT | | | • | |

9.18.4.7.3 Function model 254 - Bus controller

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------|----------------------|-------------------------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| 258 | 0 | Dali_State | UINT | • | | | |
| 263 | 3 | Dali_RequestCounter | USINT | • | | | |
| 261 | 2 | Dali_AnswerCounter | USINT | • | | | |
| 265 | 4 | Dali_Answer | USINT | • | | | |
| 257 | 0 | Dali_Enable | USINT | | | • | |
| 262 | 2 | Dali_Control | UINT | | | • | |
| 265 | 4 | Dali_Address | USINT | | | • | |
| 267 | 5 | Dali_Command | USINT | | | • | |

1) The offset specifies the position of the register within the CAN object.

9.18.4.7.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "[Using I/O modules on the bus controller](#)" on page 3789.

9.18.4.7.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.18.4.7.4 General information

DALI stands for Digital Addressable Lighting Interface and is mainly used to control lighting systems. The communication standard is intended for building automation systems and described in the EN 62386 series of standards.

9.18.4.7.4.1 The DALI protocol

The DALI standard specifies bidirectional communication based on the "request and answer" principle. A DALI network may contain multiple masters. The serial asynchronous interface transmits voltage signals at a transfer rate of 1200 bits/s.

According to the DALI standard, up to 64 individual addresses can be assigned on the network. In addition, all of the slaves in the network can be addressed via broadcast and group addresses. 16 different group addresses can be assigned independently of the individual slave addresses. This makes it possible to send a command to multiple slaves at the same time.

9.18.4.7.5 DALI - Communication

The module provides the user with a channel for communicating with and controlling DALI slaves in a DALI network. The multi-master mode described in the DALI standard is accepted by the module but not actively supported.

9.18.4.7.5.1 Communication in the DALI network

The module supports all commands defined in the DALI standard.

Communication in the DALI network takes place using the 2 bytes of the following registers:

- "Address of the DALI slave" on page 2140
- "Direct or indirect command for receiver" on page 2140

Some commands are described in the DALI specification with the structure "YAAA AAAS XXXX XXXX". In order to translate this representation to the B&R interface, the two registers "DALI_Address" and "DALI_Command" must be viewed with "Byte" as the unit.

| Dali_Address | | | | | | | Dali_Command | | | | | | | | |
|--------------|---|---|---|---|---|---|--------------|---|---|---|---|---|---|---|---|
| MSB | 6 | 5 | 4 | 3 | 2 | 1 | LSB | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ |
| Y | A | A | A | A | A | A | S | X | X | X | X | X | X | X | X |

Key

| | |
|---|--------------|
| Y | Address type |
| A | Address |
| S | Command type |
| X | Command |

Address of the DALI slave

Name:

Dali_Address

This register provides the module with the address of the DALI slave being addressed. It also defines the address type (single or group address) and command type (direct or indirect command).

| Data type | Value | Information |
|-----------|----------|--|
| USINT | 0 to 159 | Single or group address for direct or indirect command |
| | 254 | Broadcast address for direct DALI command |
| | 255 | Broadcast address for indirect DALI command |

Bit structure:

| Bit | Name | Value | Information |
|-------|--------------------------------|---------|-----------------------------------|
| 0 | Type of the subsequent command | 0 | Direct DALI command |
| | | 1 | Indirect DALI command |
| 1 - 6 | Address | 0 to 63 | Address of an individual slave |
| | | 0 to 15 | Address of a group of slaves |
| 7 | Type of the subsequent address | 0 | Addressing of an individual slave |
| | | 1 | Addressing of a group of slaves |

Direct or indirect command for receiver

Name:

Dali_Command

This register provides the module with the direct or indirect command for the receiver in the DALI network.

| Data type | Value | Information |
|-----------|----------|--------------------------------|
| USINT | 0 to 255 | DALI or slave-specific command |

9.18.4.7.5.2 Status in the DALI network

Name:

Dali_State

This register is used to indicate the current status of the DALI network.

| Data type | Value |
|-----------|--------------------|
| UINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|---------|--------------------------------------|-------|------------------------------------|
| 0 | Enables/Disables the level converter | 0 | Communication off |
| | | 1 | Communication on |
| 1 | Status of the last request | 0 | Valid request not yet sent |
| | | 1 | Transmit procedure successful |
| 2 | Status of the last response | 0 | No response since the last request |
| | | 1 | Receive procedure successful |
| 3 | Collision (multi-master) | 0 | No collision |
| | | 1 | Collision in the DALI network |
| 4 - 7 | Reserved | - | |
| 8 | Transmit error | 0 | No error |
| | | 1 | Transmit procedure failed |
| 9 | Receive error | 0 | No error |
| | | 1 | Invalid response received |
| 10 | TX busy | 0 | No transmission activity |
| | | 1 | Transmission taking place |
| 11 | RX busy | 0 | No receiving activity |
| | | 1 | Receiving taking place |
| 12 - 15 | Reserved | - | |

9.18.4.7.5.3 Transmission counter

Name:

Dali_RequestCounter

This register provides the user with information about how many DALI messages have already been sent by the module.

| Data type | Value |
|-----------|----------|
| USINT | 0 to 255 |

9.18.4.7.5.4 Response counter

Name:

Dali_AnswerCounter

This register provides the user with information about how many DALI messages have already been received by the module.

| Data type | Value |
|-----------|----------|
| USINT | 0 to 255 |

9.18.4.7.5.5 Response from DALI network

Name:

Dali_Answer

This register provides the user with access to the last valid response from the downstream DALI network.

| Data type | Value |
|-----------|----------|
| USINT | 0 to 255 |

9.18.4.7.5.6 Enabling the communication channel

Name:

Dali_Enable

This register is used to enable or disable the communication channel.

| Data type | Value |
|-----------|--------------------|
| USINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|--|-------|---|
| 0 | Turn communication on/off (via software) | 0 | Turn communication channel off |
| | | 1 | Turn communication channel on |
| 1 | Turn power saving mode on/off | 0 | Supply DALI network |
| | | 1 | Turn internal power supply for the module off |
| 2 - 7 | Reserved | - | |

Information:

for communication in the DALI network, the internal power supply in the module must be turned on.

9.18.4.7.5.7 Controlling the DALI module

Name:

Dali_Control

This register is used to control the module. The respective command is transported via X2X Link and then executed by the module. The register is edge-triggered (i.e. this type of command is only triggered if the state of the respective bit changes).

| Data type | Value |
|-----------|--------------------|
| UINT | See bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|--------|---|-------|---------------------------------------|
| 0 | Requests command (pos. edge) | 0 | No action |
| | | 1 | Transmits request in the DALI network |
| 1 | Reserved | - | |
| 2 | Acknowledges the status byte (pos. edge) | 0 | No action |
| | | 1 | Resets the status byte |
| 3 | Acknowledges the transmission counter (pos. edge) | 0 | No action |
| | | 1 | Resets the transmission counter |
| 4 | Acknowledges the response counter (pos. edge) | 0 | No action |
| | | 1 | Resets the response counter |
| 5 - 15 | Reserved | - | |

9.18.4.7.6 Excerpt from the DALI specification

9.18.4.7.6.1 General

The DALI standard involves 2 different command types. Direct commands control the brightness of the lights on the DALI slave being addressed. This type of communication runs only from the master to the slave.

Setting the LSB in the address register will use the included command for independent digital communication. The commands are also transferred from the master to the slave. Some requests require a response from the slave. In this case, communication from the slave to the master must also be possible.

9.18.4.7.6.2 Direct DALI commands (ARC)

These commands can be used to directly set the brightness of each DALI slave. The statements 1 to 254 correspond to a brightness of the connected DALI slave based on the following formula:

$$P = 10^{\frac{\text{Value} - 1}{253/3}} * \frac{P_{\max}}{1000}$$

Command 0 can also be transmitted to switch off a DALI slave. In this case, the brightness decreases slowly at first and then shuts off when a critical power level is crossed.

Command 255 serves as an internal mask value. It is not applied by the DALI slave, which means it has no effect on its behavior.

9.18.4.7.6.3 Indirect DALI commands for lamp wattage

Indirect commands make digital communication possible on the DALI network. In addition to the commands defined in the DALI standard, some manufacturers of DALI slaves also define their own commands.

Selected standardized DALI commands

Source: EN 62386-102:2009

| Code (dec.) | Function |
|---------------------------|--|
| Indirect control commands | |
| 0 | Switches off the light immediately <ul style="list-style-type: none"> – No smooth transition |
| 1 | 200 ms dimming up <ul style="list-style-type: none"> – Possible to configure the dimming speed separately – No further change once maximum is reached – Command ignored when light is off |
| 2 | 200 ms dimming down <ul style="list-style-type: none"> – Possible to configure the dimming speed separately – No further change once minimum is reached – Command does not turn light off |
| 3 | Increases the brightness by one step <ul style="list-style-type: none"> – No smooth transition – No further change once maximum is reached – Command ignored when light is off |
| 4 | Decreases the brightness by one step <ul style="list-style-type: none"> – No smooth transition – No further change once minimum is reached – Command does not turn light off |
| 5 | Maximum brightness <ul style="list-style-type: none"> – No smooth transition – Turns the light on |
| 6 | Minimum brightness <ul style="list-style-type: none"> – No smooth transition – Turns the light on |
| 7 | Decrease brightness by one step (including switching off) <ul style="list-style-type: none"> – No smooth transition – Command can turn light off |
| 8 | Increase brightness by one step (including switching on) <ul style="list-style-type: none"> – No smooth transition – Turns the light on |
| 9 | Commence DACP sequence <ul style="list-style-type: none"> – Starts direct power control – Dimming speed adjusted dynamically by the control device – DACP sequence required at the end |
| 10 - 15 | Reserved |
| 16 - 31 | Enables scene 0 to 15 <ul style="list-style-type: none"> – Power regulated to the level stored in the scene |

9.18.4.7.6.4 Indirect DALI commands for configuration

Indirect commands make digital communication possible on the DALI network. In addition to the commands defined in the DALI standard, some manufacturers of DALI slaves also define their own commands.

Information:

Some indirect DALI commands must be repeated within 100 ms. The module does not evaluate specified addresses and commands, which means this repetition must be ensured by the application.

Selected standardized DALI commands

Source: EN 62386-102:2009

| Code (dec.) | Function | Response | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|--|---|---|-----|-------|----------|---|---|----------------------|---|--------------------------|---|---|-----------------|---|---------------------|---|---|-----------|---|----------|---|---|--|---|--|---|---|---------------------------------|---|------------------------------------|---|---|-------------------------------|---|---------------------------|---|---|------------------------------|---|---------------------------------|---|---|---|---|---|
| Configuration commands ¹⁾ | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 32 | Resets nonvolatile memory – DALI slave requires up to 300 ms for execution | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 33 | Reads out the current power level – Stores the current power value in the DTR – Command code 152 required | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 34 - 41 | Reserved | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Save DTR value ¹⁾ | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 42 | Save as maximum power value | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 43 | Save as minimum power value | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 44 | Save power value as value for event of error | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 45 | Save power value as switch-on value | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 46 | Save value as dimming time | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 47 | Save value as dimming speed | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 48 - 63 | Reserved | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Used for setting system parameters ¹⁾ | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 64 - 79 | Save DTR value as selected scene 0 to 15 – Scene number = Command number - 64 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 80 - 95 | Removes DALI slave from scene 0 to 15 – Scene number = Command number - 80 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 96 - 111 | Adds DALI slave to group 0 to 15 – Group number = Command number - 96 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 112 - 127 | Removes DALI slave from group 0 to 15 – Group number = Command number - 112 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 128 | Save DTR value as short address | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 129 - 143 | Reserved | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Request commands | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 144 | Checks the general status | <table border="1"> <thead> <tr> <th>Bit</th> <th>Value</th> <th>Function</th> </tr> </thead> <tbody> <tr> <td rowspan="2">0</td> <td>0</td> <td>DALI slave status OK</td> </tr> <tr> <td>1</td> <td>DALI slave status not OK</td> </tr> <tr> <td rowspan="2">1</td> <td>0</td> <td>Light status OK</td> </tr> <tr> <td>1</td> <td>Light status not OK</td> </tr> <tr> <td rowspan="2">2</td> <td>0</td> <td>Light off</td> </tr> <tr> <td>1</td> <td>Light on</td> </tr> <tr> <td rowspan="2">3</td> <td>0</td> <td>Last requested power level permissible</td> </tr> <tr> <td>1</td> <td>Last requested power level not permissible</td> </tr> <tr> <td rowspan="2">4</td> <td>0</td> <td>Last dimming procedure complete</td> </tr> <tr> <td>1</td> <td>Dimming procedure not yet complete</td> </tr> <tr> <td rowspan="2">5</td> <td>0</td> <td>DALI slave not in reset state</td> </tr> <tr> <td>1</td> <td>DALI slave in reset state</td> </tr> <tr> <td rowspan="2">6</td> <td>0</td> <td>DALI slave has short address</td> </tr> <tr> <td>1</td> <td>DALI slave has no short address</td> </tr> <tr> <td rowspan="2">7</td> <td>0</td> <td>Reset or control command not yet received by DALI slave</td> </tr> <tr> <td>1</td> <td>Reset or control command received by DALI slave</td> </tr> </tbody> </table> | Bit | Value | Function | 0 | 0 | DALI slave status OK | 1 | DALI slave status not OK | 1 | 0 | Light status OK | 1 | Light status not OK | 2 | 0 | Light off | 1 | Light on | 3 | 0 | Last requested power level permissible | 1 | Last requested power level not permissible | 4 | 0 | Last dimming procedure complete | 1 | Dimming procedure not yet complete | 5 | 0 | DALI slave not in reset state | 1 | DALI slave in reset state | 6 | 0 | DALI slave has short address | 1 | DALI slave has no short address | 7 | 0 | Reset or control command not yet received by DALI slave | 1 | Reset or control command received by DALI slave |
| Bit | Value | Function | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0 | 0 | DALI slave status OK | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| 1 | 0 | Light status OK | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | 1 | Light status not OK | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 2 | 0 | Light off | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | 1 | Light on | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 3 | 0 | Last requested power level permissible | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | 1 | Last requested power level not permissible | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 4 | 0 | Last dimming procedure complete | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | 1 | Dimming procedure not yet complete | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 5 | 0 | DALI slave not in reset state | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | 1 | DALI slave in reset state | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 6 | 0 | DALI slave has short address | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | 1 | DALI slave has no short address | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 7 | 0 | Reset or control command not yet received by DALI slave | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | 1 | Reset or control command received by DALI slave | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 145 | Checks communication readiness | Yes/No | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 146 | Checks for light failure | Yes/No | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 147 | Checks whether light is currently on | Yes/No | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 148 | Checks whether the last requested power value was applied | Yes/No | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 149 | Checks whether the DALI slave is in reset state | Yes/No | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 150 | Checks whether the DALI slave has a short address | Yes/No | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 151 | Checks whether the DALI slave has a version number | The response depends on the DALI slave: <ul style="list-style-type: none"> • Yes/No (DALI slave has a version number or not) • Version number | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 152 | Checks the DTR value | DTR value | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 153 | Checks the device type | DALI-specific code for categorizing DALI slaves | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 154 | Checks the physical minimum level (greater than 0) | Value of physical minimum level | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 155 | Checks for power failure | Yes/No | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Code (dec.) | Function | Response | | | | | | | | | | | | | | | | |
|-------------|---|--|-----|----------|----------|---------------|-------|----------------------|---|------------------|-----|--|--|---|---|-----------------------|---|-------------------|
| 156 - 159 | Reserved | | | | | | | | | | | | | | | | | |
| 160 | Checks the current power level | Current power level or 255 if the light is being warmed up | | | | | | | | | | | | | | | | |
| 161 | Checks the maximum value | Maximum value | | | | | | | | | | | | | | | | |
| 162 | Checks the minimum value | Minimum value | | | | | | | | | | | | | | | | |
| 163 | Checks the switch-on power level | Switch-on power level | | | | | | | | | | | | | | | | |
| 164 | Checks the power level in the event of error | Power level in the event of error | | | | | | | | | | | | | | | | |
| 165 | Checks the dimming time and dimming speed | <table border="1"> <thead> <tr> <th>Bit</th> <th>Function</th> </tr> </thead> <tbody> <tr> <td>0 - 3</td> <td>Dimming speed</td> </tr> <tr> <td>4 - 7</td> <td>Dimming time</td> </tr> </tbody> </table> | Bit | Function | 0 - 3 | Dimming speed | 4 - 7 | Dimming time | | | | | | | | | | |
| Bit | Function | | | | | | | | | | | | | | | | | |
| 0 - 3 | Dimming speed | | | | | | | | | | | | | | | | | |
| 4 - 7 | Dimming time | | | | | | | | | | | | | | | | | |
| 166 - 175 | Reserved | | | | | | | | | | | | | | | | | |
| 176 - 191 | Checks the light level for scene 0 to 15 | | | | | | | | | | | | | | | | | |
| 192 | Checks whether the DALI slave member is part of group 0 to 7 | <table border="1"> <thead> <tr> <th>Bit</th> <th>Value</th> <th>Function</th> </tr> </thead> <tbody> <tr> <td rowspan="2">0</td> <td>0</td> <td>Slave not in group 0</td> </tr> <tr> <td>1</td> <td>Slave in group 0</td> </tr> <tr> <td>...</td> <td></td> <td></td> </tr> <tr> <td rowspan="2">7</td> <td>0</td> <td>Slave not in group 7</td> </tr> <tr> <td>1</td> <td>Slave in group 7</td> </tr> </tbody> </table> | Bit | Value | Function | 0 | 0 | Slave not in group 0 | 1 | Slave in group 0 | ... | | | 7 | 0 | Slave not in group 7 | 1 | Slave in group 7 |
| Bit | Value | Function | | | | | | | | | | | | | | | | |
| 0 | 0 | Slave not in group 0 | | | | | | | | | | | | | | | | |
| | 1 | Slave in group 0 | | | | | | | | | | | | | | | | |
| ... | | | | | | | | | | | | | | | | | | |
| 7 | 0 | Slave not in group 7 | | | | | | | | | | | | | | | | |
| | 1 | Slave in group 7 | | | | | | | | | | | | | | | | |
| 193 | Checks whether the DALI slave member is part of group 8 to 15 | <table border="1"> <thead> <tr> <th>Bit</th> <th>Value</th> <th>Function</th> </tr> </thead> <tbody> <tr> <td rowspan="2">0</td> <td>0</td> <td>Slave not in group 8</td> </tr> <tr> <td>1</td> <td>Slave in group 8</td> </tr> <tr> <td>...</td> <td></td> <td></td> </tr> <tr> <td rowspan="2">7</td> <td>0</td> <td>Slave not in group 15</td> </tr> <tr> <td>1</td> <td>Slave in group 15</td> </tr> </tbody> </table> | Bit | Value | Function | 0 | 0 | Slave not in group 8 | 1 | Slave in group 8 | ... | | | 7 | 0 | Slave not in group 15 | 1 | Slave in group 15 |
| Bit | Value | Function | | | | | | | | | | | | | | | | |
| 0 | 0 | Slave not in group 8 | | | | | | | | | | | | | | | | |
| | 1 | Slave in group 8 | | | | | | | | | | | | | | | | |
| ... | | | | | | | | | | | | | | | | | | |
| 7 | 0 | Slave not in group 15 | | | | | | | | | | | | | | | | |
| | 1 | Slave in group 15 | | | | | | | | | | | | | | | | |
| 194 | Checks a 24-bit random address (H) | Random address (higher 8 bits) | | | | | | | | | | | | | | | | |
| 195 | Checks a 24-bit random address (M) | Random address (middle 8 bits) | | | | | | | | | | | | | | | | |
| 196 | Checks a 24-bit random address (L) | Random address (lower 8 bits) | | | | | | | | | | | | | | | | |
| 197 - 223 | Reserved | | | | | | | | | | | | | | | | | |
| 224 - 255 | Checks application-specific defined commands | | | | | | | | | | | | | | | | | |

- 1) Any command in the range 32 to 129 must be repeated within the next 100 ms. No other commands can be transmitted to the DALI slave being addressed during this time.

9.18.4.7.6.5 DALI special commands

In the DALI standard, special commands are described as a bit structure represented by the arrangement YAAAAAAS XXXXXXXX (see also "[Communication in the DALI network](#)" on page 2140). This section contains information about the most important special commands from the DALI specification.

Leave special modes

TERMINATE

YAAAAAAS XXXXXXXX 10100001 00000000
Switches all DALI slaves on the bus in normal mode

Write DTR

DATA TRANSFER REGISTER (DTR)

YAAAAAAS XXXXXXXX 10100011 xxxxxxxx
Writes the bit pattern xxxxxxxx to the Data Transfer Register (DTR)

Special addressing for address assignment

INITIALISE

YAAAAAAS XXXXXXXX 10100101 xxxxxxxx
Allows commands for special addressing within the next 15 minutes.

Information:

- The command must be sent twice within 100 ms.
- "TERMINATE" can be used to exit initialization early. Reinitializing (before the 15 minutes is completed) extends initialization by a further 15 minutes.

RANDOMISE

YAAAAAAS XXXXXXXX 10100111 00000000

Information:

The command must be sent twice within 100 ms.

**SEARCHADDRH
SEARCHADDRM
SEARCHADDRL**

YAAAAAAS XXXXXXXX 10110001 hhhhhhh
 10110011 mmmmmmm
 10110101 lllllll

"hhhhhhh", "mmmmmm" and "llllll" represent the currently "selected" 24-bit address in the DALI network.

COMPARE

YAAAAAAS XXXXXXXX 10101001 0000000

All slaves in the DALI network with a 24-bit address less than or equal to hhhhhhh mmmmmmm lllllll respond with YES. By repeatedly assigning new search addresses and using "COMPARE", it is possible to select the currently initialized slave with the smallest 24-bit address.

PROGRAM SHORT ADDRESS

YAAAAAAS XXXXXXXX 10110111 0aaaaaa1

The selected slave takes on the short address assigned to aaaaaa.

QUERY SHORT ADDRESS

YAAAAAAS XXXXXXXX = 10111011 0000000

The selected slave responds with its current short address. If no short address has been assigned, it responds with 255. This can be used to check the possible success of address assignment.

VERIFY SHORT ADDRESS

YAAAAAAS XXXXXXXX 10111001 0aaaaaa1

The selected slave responds with YES if the value specified on aaaaaa corresponds to its short address. This can be used to check the possible success of address assignment.

WITHDRAW

YAAAAAAS XXXXXXXX 10101011 0000000

The selected slave is excluded from the subsequent search with "COMPARE" statements but remains initialized and can be selected.

PHYSICAL SELECTION

YAAAAAAS XXXXXXXX = 10111011 0000000

The selected slave is excluded from the subsequent search with "COMPARE" statements, no longer initialized and can no longer be selected.

Additional special commands

Additional special commands can be found in the DALI standard.

9.18.4.7.7 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 100 µs |

9.18.4.7.8 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 30 ms |

9.18.5 X20(c)CS1020

Data sheet version: 3.38

9.18.5.1 General information

In addition to the standard I/O, complex devices often need to be connected. The X20CS communication modules are intended precisely for cases like this. As normal X20 electronics modules, they can be placed anywhere on the remote backplane.

- RS232 interface for serial, remote connection of complex devices to the X20 system

9.18.5.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.18.5.3 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | X20 electronics module communication |  |
| X20CS1020 | X20 interface module, 1 RS232 interface, max. 115.2 kbit/s | |
| X20cCS1020 | X20 interface module, coated, 1 RS232 interface, max. 115.2 kbit/s | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |
| X20cBM11 | X20 bus module, coated, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB06 | X20 terminal block, 6-pin, 24 VDC keyed | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |

| Interface IF1 | | |
| Signal | RS232 | |
| Variant | Connection made using 12-pin X20TB12 terminal block | |
| Max. distance | 900 m | |
| Transfer rate | Max. 115.2 kbit/s | |
| FIFO buffer | 1 kB | |
| Handshake lines | RTS, CTS | |
| Controller | UART type 16C550 compatible | |
| Electrical properties | | |
| Electrical isolation | RS232 (IF1) isolated from bus RS232 (IF1) not isolated from I/O power supply | |
| Operating conditions | | |
| Mounting orientation | | |
| Horizontal | Yes | |
| Vertical | Yes | |
| Installation elevation above sea level | | |
| 0 to 2000 m | No limitations | |
| >2000 m | Reduction of ambient temperature by 0.5°C per 100 m | |
| Degree of protection per EN 60529 | IP20 | |
| Ambient conditions | | |
| Temperature | | |
| Operation | | |
| Horizontal mounting orientation | -25 to 60°C | |
| Vertical mounting orientation | -25 to 50°C | |
| Derating | See section "Derating" | |
| Storage | -40 to 85°C | |
| Transport | -40 to 85°C | |
| Relative humidity | | |
| Operation | 5 to 95%, non-condensing | Up to 100%, condensing |
| Storage | 5 to 95%, non-condensing | |
| Transport | 5 to 95%, non-condensing | |
| Mechanical properties | | |
| Note | Order 1x X20TB06 or X20T-B12 terminal block separately Order 1x X20BM11 bus module separately | Order 1x X20TB06 or X20T-B12 terminal block separately Order 1x X20cBM11 bus module separately |
| Pitch | 12.5 ^{+0.2} mm | |

Table 387: X20CS1020, X20cCS1020 - Technical data

9.18.5.5 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|--------|-----------------------------|---|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | An I/O error has occurred, see " Error message status bits " on page 2160 |
| | | | On | Error or reset status |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | Tx | Yellow | On | The module transmits data via the RS232 interface. |
| Rx | Yellow | On | The module receives data via the RS232 interface. | |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.18.5.6 Pinout

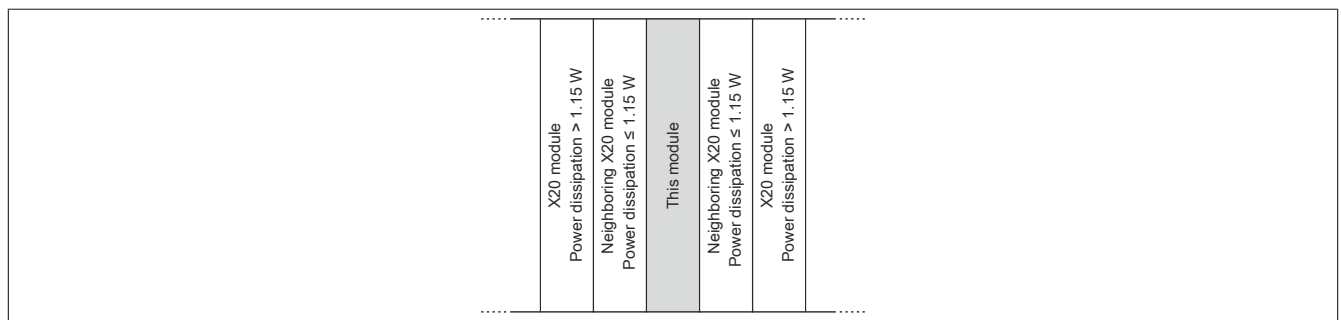

9.18.5.7 Derating

There is no derating when operated below 55°C.

During operation over 55°C, the power dissipation of the modules to the left and right of this module is not permitted to exceed 1.15 W!

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

9.18.5.8 Register description

9.18.5.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.18.5.8.2 Function model 2 - Stream and Function model 254 - Cyclic stream

Function models "Stream" and "Cyclic stream" use a module-specific driver for the operating system. The interface can be controlled using library "DvFrame" and reconfigured at runtime.

Function model - Stream

In function model "Stream", the CPU communicates with the module acyclically. The interface is relatively convenient, but the timing is very imprecise.

Function model - Cyclic stream

Function model "Cyclic stream" was implemented later. From the application's point of view, there is no difference between function models "Stream" and "Cyclic stream". Internally, however, the cyclic I/O registers are used to ensure that communication follows deterministic timing.

Information:

- In order to use function models "Stream" and "Cyclic stream", you must be using B&R controllers of type "SG4".
- These function models can only be used in X2X Link and POWERLINK networks.

| Register | Name | Data type | Read | | Write | |
|--|-----------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module - Configuration | | | | | | |
| - | AsynSize | - | | | | |
| Status messages – Configuration | | | | | | |
| 50 | CfO_RxStateIgnoreMask | UINT | | | | • |
| 6273 | CfO_ErrorID0007 | USINT | | | | • |
| Status messages – Communication | | | | | | |
| 6145 | ErrorByte | USINT | • | | | |
| | StartBitError | Bit 0 | | | | |
| | StopBitError | Bit 1 | | | | |
| | ParityError | Bit 2 | | | | |
| | RXoverrun | Bit 3 | | | | |
| 6209 | ErrorQuitByte | USINT | | | • | |
| | QuitStartBitError | Bit 0 | | | | |
| | QuitStopBitError | Bit 1 | | | | |
| | QuitParityError | Bit 2 | | | | |
| | QuitRXoverrun | Bit 3 | | | | |

9.18.5.8.3 Function model 254 - Flatstream

Flatstream provides independent communication between an X2X Link master and the module. This interface was implemented as a separate function model for the module. Serial information is transferred via cyclic input and output registers. The sequence and control bytes are used to control the data stream (see "Flatstream communication" on page 3802).

When using function model Flatstream, the user can choose whether to use library "AsFltGen" in AS for implementation or to adapt Flatstream handling directly to the individual requirements of the application.

| Register | Name | Data type | Read | | Write | |
|---|-------------------------------|-----------|--------|---------|--------|---------|

| Index + 160 | TxByteN (index N = 1 to 27) | USINT | | | • | |

9.18.5.8.4 Function model 254 - Bus controller

Function model "Bus controller" is a reduced form of function model "Flatstream". Instead of up to 27 Tx / Rx bytes, a maximum of 7 Tx / Rx bytes can be used.

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|---|----------------------|-----------------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Serial interface - Configuration | | | | | | | |

1) The offset specifies the position of the register within the CAN object.

9.18.5.8.4.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.18.5.8.4.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.18.5.8.5 Serial interface - Configuration

The user has to configure 5 registers to operate the serial interface.

9.18.5.8.5.1 Mode_IF

Name:

phyMode

phyMode_CANIO

This register is used to determine the current operating mode of the interface.

Enabling the interface is only permitted after complete configuration of the other registers. If parameters need to be changed, the interface must first be disabled.

| Data type | Value | Description |
|-----------|-------|---|
| USINT | 0 | RS232 interface disabled (bus controller default setting) |
| | 2 | RS232 interface enabled |

9.18.5.8.5.2 Baudrate_IF

Name:

phyBaud

phyBaud_CANIO

This register sets the baud rate of the interface in bit/s.

| Data type | Value | Function |
|-----------|--------|---|
| UDINT | 1200 | 1.2 kbaud |
| | 2400 | 2.4 kbaud |
| | 4800 | 4.8 kbaud |
| | 9600 | 9.6 kbaud |
| | 19200 | 19.2 kbaud |
| | 38400 | 38.4 kbaud |
| | 57600 | 57.6 kbaud (bus controller default setting) |
| | 115200 | 115.2 kbaud |

9.18.5.8.5.3 Databit_IF

Name:

phyData

phyData_CANIO

This register is used to specify the number of bits to be transferred for each character.

| Data type | Value | Description |
|-----------|-------|--|
| USINT | 7 | 7 data bits |
| | 8 | 8 data bits (bus controller default setting) |

9.18.5.8.5.4 Stopbit_IF

Name:

phyStop

phyStop_CANIO

This register is used to define the number of stop bits.

| Data type | Values | Explanation |
|-----------|--------|---|
| USINT | 2 | 1 stop bit (bus controller default setting) |
| | 4 | 2 stop bits |

9.18.5.8.5.5 Parity_IF

Name:

phyParity

phyParity_CANIO

This register is used to define the parity check type. Possible values are ASCII coded.

| Data type | Value | Description |
|-----------|-------|---|
| USINT | 48 | "0" - (low) bit is always 0 |
| | 49 | "1" - (high) bit is always 1 |
| | 69 | "E" - (even) even parity (bus controller default setting) |
| | 78 | "N" - (no) no bit |
| | 79 | "O" - (odd) odd parity |

9.18.5.8.6 Handshake - Configuration

In order to guarantee that serial communication runs smoothly, the size of the receive buffer in the module must be known. In addition, the user can configure a software or hardware handshake algorithm.

9.18.5.8.6.1 Locking the receive buffer

Name:
rxILock
rxILock_CANIO

This register is used to configure the upper threshold of the receive buffer.

The two registers "Lock" and "Unlock" can be used for "flow control" monitoring of the communication. If the amount of data from the module input exceeds the value of register "Lock", flow control switches to state "Passive". To return to state "Active" or "Ready", the amount of data in the receive buffer must fall below the default value of register "Unlock".

Information:

These registers simulate the behavior of a Schmitt trigger, so the value of register "Lock" must be greater than the value of register "Unlock".

| Data type | Value | Description |
|-----------|-----------|--|
| UINT | 0 to 4095 | Upper limit of receive buffer. Bus controller default setting: 1024 |

9.18.5.8.6.2 Unlocking the receive buffer

Name:
rxIUnlock
rxIUnlock_CANIO

This register is used to configure the lower threshold of the receive buffer.

The two registers "Lock" and "Unlock" can be used for "flow control" monitoring of the communication. If the amount of data from the module input exceeds the value of register "Lock", flow control switches to state "Passive". To return to state "Active" or "Ready", the amount of data in the receive buffer must fall below the default value of register "Unlock".

Information:

These registers simulate the behavior of a Schmitt trigger, so the value of register "Lock" must be greater than the value of register "Unlock".

| Data type | Value | Description |
|-----------|-----------|---|
| UINT | 0 to 4095 | Lower limit of receive buffer. Bus controller default setting: 512 |

9.18.5.8.6.3 RTS evaluation

Name:
hshRxF
hshRxF_CANIO

These registers can be used to configure how the hardware handshake line RTS is controlled depending on the fill level of the receive buffer.

The two registers "TxF" and "RxF" can be used to enable flow control for the input or output direction. Communication takes place here via a ring buffer.

Information:

Only one hsh register can be configured for controlling the RTS line.

| Data type | Value | Description |
|-----------|-------|---|
| USINT | 0 | RTS line freely available for other flow control methods (bus controller default setting) |
| | 16 | RTS line is controlled by the fill level of the receive buffer |

9.18.5.8.6.4 CTS evaluation

Name:

hshTxF

hshTxF_CANIO

This register is used to configure how the CTS hardware handshake line is evaluated. Make sure wiring to the peer station is correct when CTS query is enabled.

The two registers "TxF" and "RxF" can be used to enable flow control for the input or output direction. Communication takes place here via a ring buffer.

| Data type | Value | Description |
|-----------|-------|--|
| USINT | 0 | CTS line ignored, transmission can take place at any time (bus controller default setting) |
| | 1 | CTS line active and is being used for flow control, transmit enable from the peer station |

9.18.5.8.6.5 Turn on software handshake

Name:

hssXOn

hssXOn_CANIO

This register can be used to configure the XOn character. The value 17 is the default, but any other value can also be configured.

The two registers "Xon" and "Xoff" can be used to initiate a software handshake for flow control. A valid ASCII character must be configured in both registers for this.

| Data type | Value | Description |
|-----------|----------|--|
| UINT | 0 to 255 | XOn ASCII character |
| | 65535 | No software handshake (bus controller default setting) |

9.18.5.8.6.6 Turn off software handshake

Name:

hssXOff

hssXOff_CANIO

This register can be used to configure the XOff character. The value 19 is the default, but any other value can also be configured.

The two registers "Xon" and "Xoff" can be used to initiate a software handshake for flow control. A valid ASCII character must be configured in both registers for this.

| Data type | Value | Description |
|-----------|----------|--|
| UINT | 0 to 255 | XOff ASCII character |
| | 65535 | No software handshake (bus controller default setting) |

9.18.5.8.6.7 Handshake repetition

Name:

hssPeriod

hssPeriod_CANIO

When using a software handshake, some applications require periodic repetition of the current status. The repeat time can be defined in this register in ms for this purpose.

| Data type | Value | Description |
|-----------|--------------|---|
| UINT | 0 | Automatic status repeat disabled |
| | 500 to 10000 | Retry interval in ms. Bus controller default setting: 5000 |

9.18.5.8.6.8 Enable handshake manually

Name:
hshSet
hshSet_CANIO

The two registers "Set" and "Clr" can be used to manually manage the handshake via the application. These registers can be used to force the output level of the RTS hardware handshake line to remain active.

Information:

Only one hsh register can be configured for controlling the RTS line.

| Data type | Value | Description |
|-----------|-------|---|
| USINT | 0 | RTS line freely available for other flow control methods (bus controller default setting) |
| | 16 | RTS line enabled |

9.18.5.8.6.9 Disable handshake manually

Name:
hshClr
hshClr_CANIO

The two registers "Set" and "Clr" can be used to manually manage the handshake via the application. These registers can be used to force the output level of the RTS hardware handshake line to remain passive.

Information:

Only one hsh register can be configured for controlling the RTS line.

| Data type | Value | Description |
|-----------|-------|---|
| USINT | 0 | RTS line freely available for other flow control methods (bus controller default setting) |
| | 16 | RTS line disabled |

9.18.5.8.6.10 Frame detection

Name:
hshFrm
hshFrm_CANIO

This register generally enables hardware-based frame detection. The RTS line is enabled as long as data is being transmitted. This Tx framing mode can be used to control external interface converters.

Information:

Only one hsh register can be configured for controlling the RTS line.

| Data type | Values | Explanation |
|-----------|--------|---|
| USINT | 0 | RTS line freely available for other flow control methods (bus controller default setting) |
| | 16 | Tx framing enabled for RTS line |
| | 80 | Tx framing enabled for RTS line (without echo) |

9.18.5.8.6.11 Inverting RTS/CTS

Name:
hshInv
hshInv_CANIO

This register can be used to create a logical inverse of the RTS/CTS signals.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|--|
| 0 | CTS signal | 0 | Inversion off (bus controller default setting) |
| | | 1 | Inversion on |
| 1 - 3 | Reserved | 0 | |
| 4 | RTS signal | 0 | Inversion off (bus controller default setting) |
| | | 1 | Inversion on |
| 5 - 7 | Reserved | 0 | |

9.18.5.8.7 Frame - Configuration

Different message termination codes can be specified in order to correctly create transmitted Tx frames and correctly interpret received Rx frames.

9.18.5.8.7.1 Terminating when a receive timeout occurs

Name:
rxCto
rxCto_CANIO

This register is used to set the duration until a receive timeout is triggered.

The message is considered to be terminated when nothing is transferred for the specified duration.

The time is specified here in characters to ensure that it is independent of the transfer rate. The number of characters is then multiplied by the time needed to transfer a character.

| Data type | Value | Description |
|-----------|------------|---|
| UINT | 0 | Function disabled |
| | 1 to 65535 | Receive timeout in characters. Bus controller default setting: 4 |

9.18.5.8.7.2 Terminating when a transmit timeout occurs

Name:
txCto
txCto_CANIO

This register is used to set the duration until a transmit timeout is triggered.

The message is considered to be terminated when nothing is transferred for the specified duration.

The time is specified here in characters to ensure that it is independent of the transfer rate. The number of characters is then multiplied by the time needed to transfer a character.

| Data type | Value | Description |
|-----------|------------|--|
| UINT | 0 | Function disabled |
| | 1 to 65535 | Transmit timeout in characters. Bus controller default setting: 5 |

9.18.5.8.7.3 Maximum number of bytes received

Name:
rxEomSize
rxEomSize_CANIO

These registers configure the maximum number of bytes in the receive frame.

The message is considered to be ended as soon as a frame with the specified size in bytes is transferred. The longest possible frame length is the size of the 4096-byte receive buffer. Larger frames cause the Receive Overrun error.

| Data type | Value | Description |
|-----------|-----------|---|
| UINT | 0 | Function disabled |
| | 1 to 4096 | Configurable receive frame length in characters. Bus controller default setting: 256 |

9.18.5.8.7.4 Maximum number of bytes transmitted

Name:
txEomSize
txEomSize_CANIO

These registers configure the maximum number of bytes in the transmit frame.

The message is considered to be ended as soon as a frame with the specified size in bytes is transferred. The longest possible frame length is the size of the 4096-byte transmit buffer. The configured transmit timeout is maintained after the frame has been sent.

| Data type | Value | Description |
|-----------|-----------|---|
| UINT | 0 | Function disabled |
| | 1 to 4096 | Configurable transmit frame length in characters. Bus controller default setting: 4096 |

9.18.5.8.7.5 Define receive terminator

Name:

rxEomChar0 to rxEomChar3

rxEomChar0_CANIO to rxEomChar3_CANIO

It is possible to configure a receive terminator for all registers.

The message is considered to be terminated as soon as one of the defined characters is transferred.

| Data type | Value | Description |
|-----------|----------|--|
| UINT | 0 to 255 | Frame terminator (ASCII code) |
| | 65535 | Function disabled (bus controller default setting) |

9.18.5.8.7.6 Define transmit terminator

Name:

txEomChar0 to txEomChar3

txEomChar0_CANIO to txEomChar3_CANIO

It is possible to configure a transmit terminator for all registers.

The message is considered to be terminated as soon as one of the defined characters is transferred.

| Data type | Value | Description |
|-----------|----------|--|
| UINT | 0 to 255 | Frame terminator (ASCII code) |
| | 65535 | Function disabled (bus controller default setting) |

9.18.5.8.8 Status messages - Configuration

The status messages provide the user with information about the current situation in the downstream serial network.

9.18.5.8.8.1 Error detection setting

Name:

CfO_RxStatelgnoreMask

CfO_RxStatelgnoreMask_CANIO

This register has a direct effect on UART operation. Error detection in general can be disabled using the low byte. If error detection is not disabled, the high byte can be used to specify that a detected error should be interpreted as the end of the message.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| UINT | See bit structure. | 0 |

Bit structure:

| Bit | Name | Value | Information |
|--------|--|-------|---|
| 0 - 3 | Reserved | 0 | |
| 4 | StartBitError | 0 | Detect invalid start bit (bus controller default setting) |
| | | 1 | Ignore |
| 5 | StopBitError | 0 | Detect invalid stop bit (bus controller default setting) |
| | | 1 | Ignore |
| 6 | ParityError | 0 | Detect invalid parity bit (bus controller default setting) |
| | | 1 | Ignore |
| 7 | RXoverrun | 0 | Detect overflow in receive direction (bus controller default setting) |
| | | 1 | Ignore |
| 8 - 11 | Reserved | 0 | |
| 12 | StartBitError corresponds to the end of the frame (if bit 4 = 0) | 0 | Indicate error in module only (bus controller default setting) |
| | | 1 | Also signal end of frame |
| 13 | StopBitError corresponds to the end of the frame (if bit 5 = 0) | 0 | Indicate error in module only (bus controller default setting) |
| | | 1 | Also signal end of frame |
| 14 | ParityError corresponds to the end of the frame (if bit 6 = 0) | 0 | Indicate error in module only (bus controller default setting) |
| | | 1 | Also signal end of frame |
| 15 | RXoverrun corresponds to the end of the frame (if bit 7 = 0) | 0 | Indicate error in module only (bus controller default setting) |
| | | 1 | Also signal end of frame |

9.18.5.8.8.2 Forward error to the application

Name:

CfO_ErrorID0007

This register sets which error messages are forwarded to the application.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Name | Value | Information |
|-------|---------------|-------|---|
| 0 | StartBitError | 0 | Ignore (bus controller default setting) |
| | | 1 | Indicating a faulty start bit |
| 1 | StopBitError | 0 | Ignore (bus controller default setting) |
| | | 1 | Indicating a faulty stop bit |
| 2 | ParityError | 0 | Ignore (bus controller default setting) |
| | | 1 | Indicating a faulty parity bit |
| 3 | RXoverrun | 0 | Ignore (bus controller default setting) |
| | | 1 | Indicating an overflow in the receive direction |
| 4 - 7 | Reserved | 0 | |

9.18.5.8.9 Status messages - Communication

After configuration is completed, up to four status messages can be evaluated in the application.

9.18.5.8.9.1 Error message status bits

Name:
StartBitError
StopBitError
ParityError
RXoverrun

This register transfers the individual bits that indicate an error. If a error occurs, the corresponding bit is set and maintained until it is acknowledged.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|---------------|-------|--|
| 0 | StartBitError | 0 | No error |
| | | 1 | Start bit error occurred ¹⁾ |
| 1 | StopBitError | 0 | No error |
| | | 1 | Stop bit error occurred ¹⁾ |
| 2 | ParityError | 0 | No error |
| | | 1 | Parity bit error occurred ¹⁾ |
| 3 | RXoverrun | 0 | No error |
| | | 1 | Receive buffer overflow occurred ²⁾ |
| 4 - 7 | Reserved | 0 | |

- 1) This error can result from things such as mismatched interface configurations or problems with the wiring.
- 2) This data point reports a receive buffer overrun. The buffer capacity on the module is exhausted and all subsequent data arriving at the interface is lost. An overrun always means that the data received on the module is not read fast enough by the higher-level system. The solution here is to optimize the cycle times of all transfer routes and task classes involved and utilize the available handshake options.

9.18.5.8.9.2 Acknowledging the status bits

Name:
QuitStartBitError
QuitStopBitError
QuitParityError
QuitRXoverrun

This register is used to transfer the individual bits that acknowledge an indicated error state. After one of the bits has been set, it can be reset using the corresponding acknowledgment bit.

If the error is still actively pending, the error status bit is not deleted. The acknowledgment bit can only be reset if the error status bit is no longer set.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-------------------|-------|---|
| 0 | QuitStartBitError | 0 | No acknowledgment |
| | | 1 | Acknowledge start bit error |
| 1 | QuitStopBitError | 0 | No acknowledgment |
| | | 1 | Acknowledge stop bit error |
| 2 | QuitParityError | 0 | No acknowledgment |
| | | 1 | Acknowledge parity bit error |
| 3 | QuitRXoverrun | 0 | No acknowledgment |
| | | 1 | Acknowledge receive buffer overflow error |
| 4 - 7 | Reserved | 0 | |

9.18.5.8.10 Flatstream communication

For a description of Flatstream communication, see ["Flatstream communication" on page 3802](#)

9.18.5.8.11 Serial with FlatStream

When using FlatStream communication, the module acts as a bridge between the X2X Link master and an intelligent field device connected to the module. FlatStream mode can be used for either point-to-point connections as well as for multidrop systems. Specific algorithms such as timeout and checksum monitoring are usually managed automatically. During normal operation, the user does not have access to these details.

In a serial network, the module is always the master (DTE). Various adjustments can be made to ensure that signals are transmitted without errors.

The user can, for example, define a handshake algorithm or set the baud rate in order to adapt the transmission quality to the requirements of the application.

Operation

When using FlatStream, the general structure of the FlatStream frame must be maintained.

| Input/Output sequence | Tx/Rx bytes | |
|-----------------------|--------------------------|--|
| (unchanged) | Control byte (unchanged) | Serial frame (without handshake or similar measures) |

9.18.5.8.12 Acyclic frame size

Name:

AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.

Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

| Data type | Value | Information |
|-----------|---------|---|
| - | 8 to 28 | Acyclic frame size in bytes. Default = 24 |

9.18.5.8.13 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.18.5.8.14 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 200 μ s |

9.18.6 X20(c)CS1030

Data sheet version: 3.27

9.18.6.1 General information

In addition to the standard I/O, complex devices often need to be connected. The X20CS communication modules are intended precisely for cases like this. As normal X20 electronics modules, they can be placed anywhere on the remote backplane.

- RS485/RS422 interface for serial, remote connection of complex devices to the X20 system
- Integrated terminating resistor

9.18.6.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.18.6.3 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | X20 electronics module communication |  |
| X20CS1030 | X20 interface module, 1 RS422/485 interface, max. 115.2 kbit/s | |
| X20cCS1030 | X20 interface module, coated, 1 RS422/485 interface, max. 115.2 kbit/s | |

Table 389: X20CS1030, X20cCS1030 - Technical data

9.18.6.5 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|--------|-----------------------------|---|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | e | Red | On | RUN mode |
| | | | Off | No power to module or everything OK |
| | | | Single flash | An I/O error has occurred, see " Error message status bits " on page 2175 |
| | e + r | Red on / Green single flash | Error or reset status | Invalid firmware |
| | Tx | Yellow | On | The module transmits data via the RS485/RS422 interface |
| | Rx | Yellow | On | The module receives data via the RS485/RS422 interface |
| T | Yellow | On | Terminating resistor integrated in the module switched on | |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.18.6.6 Pinout

RS485 mode

RS422 mode

9.18.6.7 Terminating resistor

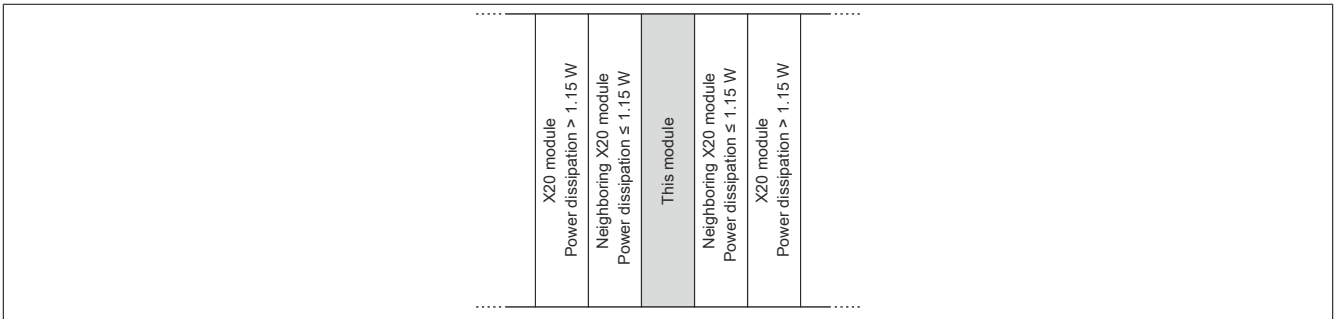

A terminating resistor is integrated in the communication module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "T" LED.

9.18.6.8 Derating

There is no derating when operated below 55°C.

During operation over 55°C, the power dissipation of the modules to the left and right of this module is not permitted to exceed 1.15 W!

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

9.18.6.9 Register description

9.18.6.9.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.18.6.9.2 Function model 2 - Stream and Function model 254 - Cyclic stream

Function models "Stream" and "Cyclic stream" use a module-specific driver for the operating system. The interface can be controlled using library "DvFrame" and reconfigured at runtime.

Function model - Stream

In function model "Stream", the CPU communicates with the module acyclically. The interface is relatively convenient, but the timing is very imprecise.

Function model - Cyclic stream

Function model "Cyclic stream" was implemented later. From the application's point of view, there is no difference between function models "Stream" and "Cyclic stream". Internally, however, the cyclic I/O registers are used to ensure that communication follows deterministic timing.

Information:

- In order to use function models "Stream" and "Cyclic stream", you must be using B&R controllers of type "SG4".
- These function models can only be used in X2X Link and POWERLINK networks.

| Register | Name | Data type | Read | | Write | |
|--|-----------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module – Configuration | | | | | | |
| - | AsynSize | - | | | | |
| Status messages – Configuration | | | | | | |
| 50 | CfO_RxStateIgnoreMask | UINT | | | | • |
| 6273 | CfO_ErrorID0007 | USINT | | | | • |
| Status messages – Communication | | | | | | |

| | StopBitError | Bit 1 | | | | |
| | ParityError | Bit 2 | | | | |
| | RXoverrun | Bit 3 | | | | |
| 6209 | ErrorQuitByte | USINT | | | • | |
| | QuitStartBitError | Bit 0 | | | | |
| | QuitStopBitError | Bit 1 | | | | |
| | QuitParityError | Bit 2 | | | | |
| | QuitRXoverrun | Bit 3 | | | | |

9.18.6.9.3 Function model 254 - Flatstream

Flatstream provides independent communication between an X2X Link master and the module. This interface was implemented as a separate function model for the module. Serial information is transferred via cyclic input and output registers. The sequence and control bytes are used to control the data stream (see "Flatstream communication" on page 3802).

When using function model Flatstream, the user can choose whether to use library "AsFltGen" in AS for implementation or to adapt Flatstream handling directly to the individual requirements of the application.

| Register | Name | Data type | Read | | Write | |
|---|-------------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Serial interface - Configuration | | | | | | |

| | QuitStartBitError | Bit 0 | | | | |
| | QuitStopBitError | Bit 1 | | | | |
| | QuitParityError | Bit 2 | | | | |
| | QuitRXoverrun | Bit 3 | | | | |
| Flatstream | | | | | | |
| 225 | OutputMTU | USINT | | | | • |
| 227 | InputMTU | USINT | | | | • |
| 229 | Mode | USINT | | | | • |
| 231 | Forward | USINT | | | | • |
| 238 | ForwardDelay | UINT | | | | • |
| 128 | InputSequence | USINT | • | | | |
| Index + 128 | RxByteN (index N = 1 to 27) | USINT | • | | | |
| 160 | OutputSequence | USINT | | | • | |
| Index + 160 | TxByteN (index N = 1 to 27) | USINT | | | • | |

9.18.6.9.4 Function model 254 - Bus controller

Function model "Bus controller" is a reduced form of function model "Flatstream". Instead of up to 27 Tx / Rx bytes, a maximum of 7 Tx / Rx bytes can be used.

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|---|----------------------|-----------------------------|-----------|--------|------------|--------|------------|
| | | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |
| Serial interface - Configuration | | | | | | | |

| 160 | 0 | OutputSequence | USINT | | | • | |
| Index + 160 | Index | TxByteN (Index N = 1 to 7) | USINT | | | • | |

1) The offset specifies the position of the register within the CAN object.

9.18.6.9.4.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.18.6.9.4.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.18.6.9.5 Serial interface - Configuration

The user has to configure 5 registers to operate the serial interface.

9.18.6.9.5.1 Mode_IF

Name:

phyMode

phyMode_CANIO

This register is used to determine the current operating mode of the interface.

Enabling the interface is only permitted after complete configuration of the other registers. If parameters need to be changed, the interface must first be disabled.

| Data type | Value | Description |
|-----------|-------|---|
| USINT | 0 | Interface disabled (bus controller default setting) |
| | 4 | RS422 interface enabled ¹⁾ |
| | 5 | RS422 interface enables as a bus ²⁾ |
| | 6 | RS485 interface enabled with echo |
| | 7 | RS485 interface enabled without echo |

1) Connection between 2 stations

2) Connections between multiple stations possible. Transmit lines connected as with RS485 TriState.

9.18.6.9.5.2 Baudrate_IF

Name:

phyBaud

phyBaud_CANIO

This register sets the baud rate of the interface in bit/s.

| Data type | Value | Function |
|-----------|--------|---|
| UDINT | 1200 | 1.2 kbaud |
| | 2400 | 2.4 kbaud |
| | 4800 | 4.8 kbaud |
| | 9600 | 9.6 kbaud |
| | 19200 | 19.2 kbaud |
| | 38400 | 38.4 kbaud |
| | 57600 | 57.6 kbaud (bus controller default setting) |
| | 115200 | 115.2 kbaud |

9.18.6.9.5.3 Databit_IF

Name:

phyData

phyData_CANIO

This register is used to specify the number of bits to be transferred for each character.

| Data type | Value | Description |
|-----------|-------|--|
| USINT | 7 | 7 data bits |
| | 8 | 8 data bits (bus controller default setting) |

9.18.6.9.5.4 Stopbit_IF

Name:

phyStop

phyStop_CANIO

This register is used to define the number of stop bits.

| Data type | Values | Explanation |
|-----------|--------|---|
| USINT | 2 | 1 stop bit (bus controller default setting) |
| | 4 | 2 stop bits |

9.18.6.9.5.5 Parity_IF

Name:

phyParity

phyParity_CANIO

This register is used to define the parity check type. Possible values are ASCII coded.

| Data type | Value | Description |
|-----------|-------|---|
| USINT | 48 | "0" - (low) bit is always 0 |
| | 49 | "1" - (high) bit is always 1 |
| | 69 | "E" - (even) even parity (bus controller default setting) |
| | 78 | "N" - (no) no bit |
| | 79 | "O" - (odd) odd parity |

9.18.6.9.6 Handshake - Configuration

In order to guarantee that serial communication runs smoothly, the size of the receive buffer in the module must be known. In addition, the user can configure a software or hardware handshake algorithm.

9.18.6.9.6.1 Locking the receive buffer

Name:

rxILock

rxILock_CANIO

This register is used to configure the upper threshold of the receive buffer.

The two registers "Lock" and "Unlock" can be used for "flow control" monitoring of the communication. If the amount of data from the module input exceeds the value of register "Lock", flow control switches to state "Passive". To return to state "Active" or "Ready", the amount of data in the receive buffer must fall below the default value of register "Unlock".

Information:

These registers simulate the behavior of a Schmitt trigger, so the value of register "Lock" must be greater than the value of register "Unlock".

| Data type | Value | Description |
|-----------|-----------|--|
| UINT | 0 to 4095 | Upper limit of receive buffer. Bus controller default setting: 1024 |

9.18.6.9.6.2 Unlocking the receive buffer

Name:

rxIUnlock

rxIUnlock_CANIO

This register is used to configure the lower threshold of the receive buffer.

The two registers "Lock" and "Unlock" can be used for "flow control" monitoring of the communication. If the amount of data from the module input exceeds the value of register "Lock", flow control switches to state "Passive". To return to state "Active" or "Ready", the amount of data in the receive buffer must fall below the default value of register "Unlock".

Information:

These registers simulate the behavior of a Schmitt trigger, so the value of register "Lock" must be greater than the value of register "Unlock".

| Data type | Value | Description |
|-----------|-----------|---|
| UINT | 0 to 4095 | Lower limit of receive buffer. Bus controller default setting: 512 |

9.18.6.9.6.3 Turn on software handshake

Name:

hssXOn

hssXOn_CANIO

This register can be used to configure the XOn character. The value 17 is the default, but any other value can also be configured.

The two registers "Xon" and "Xoff" can be used to initiate a software handshake for flow control. A valid ASCII character must be configured in both registers for this.

| Data type | Value | Description |
|-----------|----------|--|
| UINT | 0 to 255 | XOn ASCII character |
| | 65535 | No software handshake (bus controller default setting) |

9.18.6.9.6.4 Turn off software handshake

Name:

hssXOff

hssXOff_CANIO

This register can be used to configure the XOff character. The value 19 is the default, but any other value can also be configured.

The two registers "Xon" and "Xoff" can be used to initiate a software handshake for flow control. A valid ASCII character must be configured in both registers for this.

| Data type | Value | Description |
|-----------|----------|--|
| UINT | 0 to 255 | XOff ASCII character |
| | 65535 | No software handshake (bus controller default setting) |

9.18.6.9.6.5 Handshake repetition

Name:

hssPeriod

hssPeriod_CANIO

When using a software handshake, some applications require periodic repetition of the current status. The repeat time can be defined in this register in ms for this purpose.

| Data type | Value | Description |
|-----------|--------------|---|
| UINT | 0 | Automatic status repeat disabled |
| | 500 to 10000 | Retry interval in ms. Bus controller default setting: 5000 |

9.18.6.9.7 Frame - Configuration

Different message termination codes can be specified in order to correctly create transmitted Tx frames and correctly interpret received Rx frames.

9.18.6.9.7.1 Terminating when a receive timeout occurs

Name:
rxCto
rxCto_CANIO

This register is used to set the duration until a receive timeout is triggered.

The message is considered to be terminated when nothing is transferred for the specified duration.

The time is specified here in characters to ensure that it is independent of the transfer rate. The number of characters is then multiplied by the time needed to transfer a character.

| Data type | Value | Description |
|-----------|------------|---|
| UINT | 0 | Function disabled |
| | 1 to 65535 | Receive timeout in characters. Bus controller default setting: 4 |

9.18.6.9.7.2 Terminating when a transmit timeout occurs

Name:
txCto
txCto_CANIO

This register is used to set the duration until a transmit timeout is triggered.

The message is considered to be terminated when nothing is transferred for the specified duration.

The time is specified here in characters to ensure that it is independent of the transfer rate. The number of characters is then multiplied by the time needed to transfer a character.

| Data type | Value | Description |
|-----------|------------|--|
| UINT | 0 | Function disabled |
| | 1 to 65535 | Transmit timeout in characters. Bus controller default setting: 5 |

9.18.6.9.7.3 Maximum number of bytes received

Name:
rxEomSize
rxEomSize_CANIO

These registers configure the maximum number of bytes in the receive frame.

The message is considered to be ended as soon as a frame with the specified size in bytes is transferred. The longest possible frame length is the size of the 4096-byte receive buffer. Larger frames cause the Receive Overrun error.

| Data type | Value | Description |
|-----------|-----------|---|
| UINT | 0 | Function disabled |
| | 1 to 4096 | Configurable receive frame length in characters. Bus controller default setting: 256 |

9.18.6.9.7.4 Maximum number of bytes transmitted

Name:
txEomSize
txEomSize_CANIO

These registers configure the maximum number of bytes in the transmit frame.

The message is considered to be ended as soon as a frame with the specified size in bytes is transferred. The longest possible frame length is the size of the 4096-byte transmit buffer. The configured transmit timeout is maintained after the frame has been sent.

| Data type | Value | Description |
|-----------|-----------|---|
| UINT | 0 | Function disabled |
| | 1 to 4096 | Configurable transmit frame length in characters. Bus controller default setting: 4096 |

9.18.6.9.7.5 Define receive terminator

Name:

rxEomChar0 to rxEomChar3

rxEomChar0_CANIO to rxEomChar3_CANIO

It is possible to configure a receive terminator for all registers.

The message is considered to be terminated as soon as one of the defined characters is transferred.

| Data type | Value | Description |
|-----------|----------|--|
| UINT | 0 to 255 | Frame terminator (ASCII code) |
| | 65535 | Function disabled (bus controller default setting) |

9.18.6.9.7.6 Define transmit terminator

Name:

txEomChar0 to txEomChar3

txEomChar0_CANIO to txEomChar3_CANIO

It is possible to configure a transmit terminator for all registers.

The message is considered to be terminated as soon as one of the defined characters is transferred.

| Data type | Value | Description |
|-----------|----------|--|
| UINT | 0 to 255 | Frame terminator (ASCII code) |
| | 65535 | Function disabled (bus controller default setting) |

9.18.6.9.8 Status messages - Configuration

The status messages provide the user with information about the current situation in the downstream serial network.

9.18.6.9.8.1 Error detection setting

Name:

CfO_RxStatelgnoreMask

CfO_RxStatelgnoreMask_CANIO

This register has a direct effect on UART operation. Error detection in general can be disabled using the low byte. If error detection is not disabled, the high byte can be used to specify that a detected error should be interpreted as the end of the message.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| UINT | See bit structure. | 0 |

Bit structure:

| Bit | Name | Value | Information |
|--------|--|-------|---|
| 0 - 3 | Reserved | 0 | |
| 4 | StartBitError | 0 | Detect invalid start bit (bus controller default setting) |
| | | 1 | Ignore |
| 5 | StopBitError | 0 | Detect invalid stop bit (bus controller default setting) |
| | | 1 | Ignore |
| 6 | ParityError | 0 | Detect invalid parity bit (bus controller default setting) |
| | | 1 | Ignore |
| 7 | RXoverrun | 0 | Detect overflow in receive direction (bus controller default setting) |
| | | 1 | Ignore |
| 8 - 11 | Reserved | 0 | |
| 12 | StartBitError corresponds to the end of the frame (if bit 4 = 0) | 0 | Indicate error in module only (bus controller default setting) |
| | | 1 | Also signal end of frame |
| 13 | StopBitError corresponds to the end of the frame (if bit 5 = 0) | 0 | Indicate error in module only (bus controller default setting) |
| | | 1 | Also signal end of frame |
| 14 | ParityError corresponds to the end of the frame (if bit 6 = 0) | 0 | Indicate error in module only (bus controller default setting) |
| | | 1 | Also signal end of frame |
| 15 | RXoverrun corresponds to the end of the frame (if bit 7 = 0) | 0 | Indicate error in module only (bus controller default setting) |
| | | 1 | Also signal end of frame |

9.18.6.9.8.2 Forward error to the application

Name:

CfO_ErrorID0007

This register sets which error messages are forwarded to the application.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Name | Value | Information |
|-------|---------------|-------|---|
| 0 | StartBitError | 0 | Ignore (bus controller default setting) |
| | | 1 | Indicating a faulty start bit |
| 1 | StopBitError | 0 | Ignore (bus controller default setting) |
| | | 1 | Indicating a faulty stop bit |
| 2 | ParityError | 0 | Ignore (bus controller default setting) |
| | | 1 | Indicating a faulty parity bit |
| 3 | RXoverrun | 0 | Ignore (bus controller default setting) |
| | | 1 | Indicating an overflow in the receive direction |
| 4 - 7 | Reserved | 0 | |

9.18.6.9.9 Status messages - Communication

After configuration is completed, up to four status messages can be evaluated in the application.

9.18.6.9.9.1 Error message status bits

Name:
StartBitError
StopBitError
ParityError
RXoverrun

This register transfers the individual bits that indicate an error. If a error occurs, the corresponding bit is set and maintained until it is acknowledged.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|---------------|-------|--|
| 0 | StartBitError | 0 | No error |
| | | 1 | Start bit error occurred ¹⁾ |
| 1 | StopBitError | 0 | No error |
| | | 1 | Stop bit error occurred ¹⁾ |
| 2 | ParityError | 0 | No error |
| | | 1 | Parity bit error occurred ¹⁾ |
| 3 | RXoverrun | 0 | No error |
| | | 1 | Receive buffer overflow occurred ²⁾ |
| 4 - 7 | Reserved | 0 | |

- 1) This error can result from things such as mismatched interface configurations or problems with the wiring.
- 2) This data point reports a receive buffer overrun. The buffer capacity on the module is exhausted and all subsequent data arriving at the interface is lost. An overrun always means that the data received on the module is not read fast enough by the higher-level system. The solution here is to optimize the cycle times of all transfer routes and task classes involved and utilize the available handshake options.

9.18.6.9.9.2 Acknowledging the status bits

Name:
QuitStartBitError
QuitStopBitError
QuitParityError
QuitRXoverrun

This register is used to transfer the individual bits that acknowledge an indicated error state. After one of the bits has been set, it can be reset using the corresponding acknowledgment bit.

If the error is still actively pending, the error status bit is not deleted. The acknowledgment bit can only be reset if the error status bit is no longer set.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Name | Value | Information |
|-------|-------------------|-------|---|
| 0 | QuitStartBitError | 0 | No acknowledgment |
| | | 1 | Acknowledge start bit error |
| 1 | QuitStopBitError | 0 | No acknowledgment |
| | | 1 | Acknowledge stop bit error |
| 2 | QuitParityError | 0 | No acknowledgment |
| | | 1 | Acknowledge parity bit error |
| 3 | QuitRXoverrun | 0 | No acknowledgment |
| | | 1 | Acknowledge receive buffer overflow error |
| 4 - 7 | Reserved | 0 | |

9.18.6.9.10 Flatstream communication

For a description of Flatstream communication, see ["Flatstream communication" on page 3802](#)

9.18.6.9.11 Serial with FlatStream

When using FlatStream communication, the module acts as a bridge between the X2X Link master and an intelligent field device connected to the module. FlatStream mode can be used for either point-to-point connections as well as for multidrop systems. Specific algorithms such as timeout and checksum monitoring are usually managed automatically. During normal operation, the user does not have access to these details.

In a serial network, the module is always the master (DTE). Various adjustments can be made to ensure that signals are transmitted without errors.

The user can, for example, define a handshake algorithm or set the baud rate in order to adapt the transmission quality to the requirements of the application.

Operation

When using FlatStream, the general structure of the FlatStream frame must be maintained.

| Input/Output sequence | Tx/Rx bytes | |
|-----------------------|--------------------------|--|
| (unchanged) | Control byte (unchanged) | Serial frame (without handshake or similar measures) |

9.18.6.9.12 Acyclic frame size

Name:

AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.

Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

| Data type | Value | Information |
|-----------|---------|---|
| - | 8 to 28 | Acyclic frame size in bytes. Default = 24 |

9.18.6.9.13 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.18.6.9.14 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 200 μ s |

9.18.7 X20CS1070

Data sheet version: 3.29

9.18.7.1 General information

In addition to the standard I/O, complex devices often need to be connected. The X20CS communication modules are intended precisely for cases like this. As normal X20 electronics modules, they can be placed anywhere on the remote backplane.

- CAN bus interface for serial, remote connection of complex devices to the X20 system
- Integrated terminating resistor

9.18.7.2 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | X20 electronics module communication |  |
| X20CS1070 | X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, object buffers in both send and receive directions | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB06 | X20 terminal block, 6-pin, 24 VDC keyed | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |

9.18.7.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|--------|-----------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | I/O error occurred <ul style="list-style-type: none"> • CAN bus: Warning, passive or off • Buffer overflow |
| | | | On | Error or reset status |
| | e + r | | Red on / Green single flash | Invalid firmware |
| | Tx | | Yellow | On |
| Rx | | Yellow | On | The module is receiving data via the CAN bus interface |
| T | | Yellow | On | Terminating resistor integrated in the module switched on |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.18.7.5 Pinout

9.18.7.6 Terminating resistor

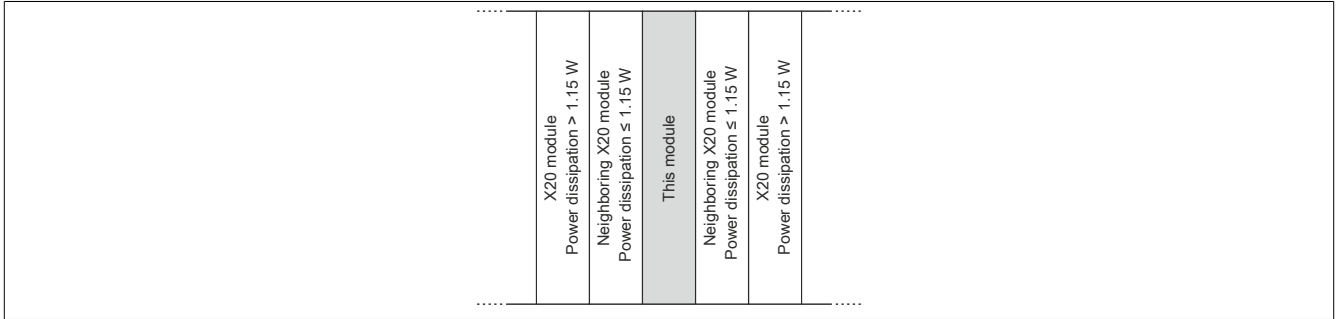

A terminating resistor is integrated in the communication module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "T" LED.

9.18.7.7 Derating

There is no derating when operated below 55°C.

During operation over 55°C, the power dissipation of the modules to the left and right of this module is not permitted to exceed 1.15 W!

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

9.18.7.8 Register description

9.18.7.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.18.7.8.2 Function model 0 - Flat

In the "Flat" function model, CAN information is transferred via cyclic input and output registers. All data for a CAN object (8 CAN data bytes, identifier, status, etc.) is accessible as individual data points (see also ["CAN object" on page 2185](#)).

To transmit a CAN object, the CAN identifier, the CAN data (max. 8 bytes) and the number of bytes to be transmitted must be written to the cyclic I/O data points. "TXCount" is then increased to send the transmission. The data is applied to the module's internal buffer (max. 18 objects) and transmitted over the CAN network at the next opportunity.

The same algorithm is used for receiving information from the CAN network. The module saves the CAN messages in its internal buffer along with the respective identifiers. The CAN identifier, CAN data (max. 8 bytes) and number of bytes to be processed are then written to the cyclic I/O data points. "RXCount" tells the application which data must be applied from these input data points.

Information:

- Libraries "ArCAN" and "CAN_Lib" cannot be used.

| Register | Name | Data type | Read | | Write | |
|----------------------------------|--|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Interface - Configuration | | | | | | |
| 257 | ConfigBaudrate | USINT | | | | • |

9.18.7.8.3 Function model 2 - Stream and Function model 254 - Cyclic stream

Function models "Stream" and "Cyclic stream" use a module-specific driver of the CPU's operating system. The interface can be controlled using libraries "ArCAN" and "CAN_Lib" and reconfigured at runtime.

Function model - Stream

In function model "Stream", the CPU communicates with the module acyclically. The interface is relatively convenient, but the timing is very imprecise.

Function model - Cyclic stream

Function model "Cyclic stream" was implemented later. From the application's point of view, there is no difference between function models "Stream" and "Cyclic stream". Internally, however, the cyclic I/O registers are used to ensure that communication follows deterministic timing.

Information:

- In order to use function models "Stream" and "Cyclic stream", you must be using B&R controllers of type "SG4".
- These function models can only be used in X2X Link and POWERLINK networks.

| Register | Name | Data type | Read | | Write | |
|----------------------------------|--|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Module - Configuration | | | | | | |
| - | AsynSize | - | | | | |
| Interface - Configuration | | | | | | |
| 6273 | CFO_ErrorID0007 | USINT | | | | • |
| Interface - Communication | | | | | | |
| 6145 | CAN error status | USINT | • | | | |
| | CANwarning | Bit 0 | | | | |
| | CANpassive | Bit 1 | | | | |
| | CANbusoff | Bit 2 | | | | |
| | CANRXoverrun | Bit 3 | | | | |
| 6209 | CAN error acknowledgment | USINT | | | • | |
| | QuitCANwarning | Bit 0 | | | | |
| | QuitCANpassive | Bit 1 | | | | |
| | QuitCANbusoff | Bit 2 | | | | |
| | QuitCANRXoverrun | Bit 3 | | | | |

9.18.7.8.4 Function model 254 - Flatstream

Flatstream provides independent communication between an X2X Link master and the module. This interface was implemented as a separate function model for the CAN module. CAN information (identifier, status, etc.) is transferred via cyclic input and output registers. The sequence and control bytes are used to control this data stream (see "Flatstream communication" on page 3802).

When using function model Flatstream, the user can choose whether to use library "AsFltGen" in AS for implementation or to adapt Flatstream handling directly to the individual requirements of the application.

Information:

- Libraries "ArCAN" and "CAN_Lib" cannot be used.
- Higher data rates can be achieved between X2X master and module compared to the "Flat" function model.

| Register | Name | Data type | Read | | Write | |
|-----------------------------------|--|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Interface - Configuration | | | | | | |
| 257 | ConfigBaudrate | USINT | | | | • |
| 259 | ConfigSJW | USINT | | | | • |
| 261 | ConfigSPO | USINT | | | | • |

| Index * 1 + 32 | TxByte1 to TxByte27 | USINT | | | • | |

9.18.7.8.5 Function model 254 - Bus controller

Function model "Bus controller" is a reduced form of function model "Flatstream". Instead of up to 27 Tx/Rx bytes, a maximum of 7 Tx/Rx bytes can be used.

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|-----------------------------------|----------------------|--------------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Interface - Configuration | | | | | | | |

| Flatstream - Configuration | | | | | | | |
| 193 | - | outputMTU | USINT | | | | • |
| 195 | - | inputMTU | USINT | | | | • |
| 197 | - | mode | USINT | | | | • |
| 199 | - | forward | USINT | | | | • |
| 206 | - | forwardDelay | UINT | | | | • |
| Flatstream - Communication | | | | | | | |
| 0 | 0 | InputSequence | USINT | • | | | |
| Index * 1 + 0 | Index * 1 + 0 | RxByte1 to RxByte7 | USINT | • | | | |
| 32 | 0 | OutputSequence | USINT | | | • | |
| Index * 1 + 32 | Index * 1 + 0 | TxByte1 to TxByte7 | USINT | | | • | |

1) The offset specifies the position of the register within the CAN object.

9.18.7.8.5.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.18.7.8.5.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.18.7.8.6 Using this module with SGC target systems

Information:

This module can only be used with SGC target systems if the function model is set to "Flatstream" or "Flat".

9.18.7.8.7 CAN object

A CAN object is always made up of a 4-byte identifier and a maximum of 8 subsequent data bytes. This also results in the relationship between CAN object length and the amount of CAN payload data. This is important because the number of CAN payload data bytes for communication via "FlatStream" always has to be determined using the frame length.

Composition of a CAN object / CAN frame

| Bytes | Function | Information |
|--------|------------------|-------------------------------|
| 1 | Code | ID bit 0 to 7 |
| 2 | | ID bit 8 to 15 |
| 3 | | ID bit 16 to 23 |
| 4 | | ID bit 24 to 31 |
| 5 - 12 | CAN payload data | 0 to 8 CAN payload data bytes |

Code

The 32 bits (4 bytes) of the CAN identifier are used as follows:

| Bit | Description | Value | Information |
|--------|---|-------|--|
| 0 | Frame format | 0 | Standard frame format (SFF) with an 11-bit identifier |
| | | 1 | Extended frame format (EFF) with an 29-bit identifier |
| 1 | Frame type | 0 | Data frame |
| | | 1 | Remote frame (RTR) |
| 2 | Reserved | - | |
| 3 - 31 | CAN identifier for telegram to be transmitted | x | Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits ¹⁾ |

1) Only bits 21 to 31 are used; bits 3 to 20 = 0.

9.18.7.8.7.1 CAN module data stream

In function model 254, the data packets to be transferred in a data stream are referred to as frames.

Information:

For the CAN module, that means:

- A frame always contains one CAN object and therefore cannot be longer than 12 bytes.
- The CAN object is only transferred to the transmit buffer after the frame has been completed.
- The CAN payload data length has a fixed relationship with the frame length and the actual size of the CAN object. The following rules apply:
 - CAN payload data length = Frame length - 4
 - Frame length = CAN payload data length + 4

9.18.7.8.8 Interface - Configuration

9.18.7.8.8.1 Transfer rate

Name:

ConfigBaudrate

"Baud rate" in the Automation Studio I/O configuration.

Configuration of the CAN transfer rate for the interface.

| Data type | Values | Bus controller default setting |
|-----------|--------------------|--------------------------------|
| USINT | See bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------|-------|---|
| 0 - 3 | Transfer rate | 0 | Interface disabled (bus controller default setting) |
| | | 1 | 10 kbit/s |
| | | 2 | 20 kbit/s |
| | | 3 | 50 kbit/s |
| | | 4 | 100 kbit/s |
| | | 5 | 125 kbit/s |
| | | 6 | 250 kbit/s |
| | | 7 | 500 kbit/s |
| | | 8 | 800 kbit/s |
| | | 9 | 1000 kbit/s |
| 4 - 7 | Reserved | - | |

9.18.7.8.8.2 Synchronization jump width

Name:

ConfigSJW

"Synchronization jump width" in the Automation Studio I/O configuration.

The synchronization jump width (SJW) is used to resynchronize the sample point within a CAN telegram.

See the CAN specification for more details on the SJW.

| Data type | Values | Explanation |
|-----------|--------|--|
| USINT | 0 to 4 | Synchronization jump width. Bus controller default setting: 3 |

9.18.7.8.8.3 Offset for the sampling instant

Name:

ConfigSPO

"Sample point offset" in the Automation Studio I/O configuration.

Offset for the sample instant of the individual bits on the CAN bus.

See the CAN specification for more details on the SPO.

| Data type | Values | Explanation |
|-----------|--------|---|
| USINT | 0 to 1 | Sample point offset. Bus controller default setting: 0 |

9.18.7.8.8.4 Start of transmission

Name:

ConfigTXtrigger

"TX objects / TX triggers" in the Automation Studio I/O configuration.

Defines the number of CAN objects that must be copied to the transmit buffer before the transmission is started.

| Data type | Values | Explanation |
|-----------|--------|---|
| UINT | 0 to 8 | Number of CAN objects in the transmit buffer before transmission is started. Bus controller default setting: 1 |

9.18.7.8.8.5 Configuration of error messages

Name:

Cfo_ErrorID0007

The error messages to be transferred must first be configured with this register. If the corresponding enable bit is not set, no error status will be sent to the higher-level system if the error occurs.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|---|
| 0 | CANwarning | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 1 | CANpassive | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 2 | CANbussoff | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 3 | CANRXoverrun | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 4 - 7 | Reserved | - | |

9.18.7.8.8.6 Size of the transmit buffer

Name:

Cfo_FIFOTXlimit

"TX FIFO size" in the Automation Studio I/O configuration.

Determines the size of the transmit buffer for the respective interface.

| Data type | Values | Explanation |
|-----------|---------|-----------------------------|
| USINT | 0 to 18 | Size of the transmit buffer |

9.18.7.8.8.7 Display of unprocessed elements remaining in the transmit/receive buffer

Name:

Cfo_TXRXinfoFlags

These registers can be used to configure for the interface that the number of unprocessed elements in the transmit or receive buffer is indicated in the upper 4 bits of registers "TXCountReadBack" and "RXCount".

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|--|
| 0 | TxFifoInfo "Mode of channel TXCountReadBack" in the Automation Studio I/O configuration | 0 | Registers "TXCountReadBack" on page 2189 and "TXCount-LatchReadBack" on page 2189 are used to read back "TXCount". |
| | | 1 | The lower 4 bits of registers "TXCountReadBack" on page 2189 and "TXCountLatchReadBack" on page 2189 are used to read back "TXCount". The upper 4 Bits are used to return the number of frames in the transmit buffer that have not been transmitted. |
| 1 | RxFifoInfo "Mode of channel RXCount" in the Automation Studio I/O configuration | 0 | Registers "RXCount" on page 2189 and "RXCountLatch" on page 2190 are used to indicate the number of telegrams that have been received. |
| | | 1 | The lower 4 bits of registers "RXCount" on page 2189 and "RX-CountLatch" on page 2190 are used to indicate the number of telegrams received. The upper 4 bits are used to indicate the number of received but not acknowledged telegrams in the receive buffer. |
| 2 - 7 | Reserved | - | |

9.18.7.8.9 Interface - Communication

9.18.7.8.9.1 CAN error status

Name:

CAN error status

The bits in this register indicate the error states defined in the CAN protocol. If an error occurs, the corresponding bit is set. For an error bit to be reset, the corresponding bit must be acknowledged (see "[CAN error acknowledgment](#)" on page 2188).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|---------------------------|
| 0 | CANwarning | 0 | No error |
| | | 1 | CANwarning error on IF1 |
| 1 | CANpassive | 0 | No error |
| | | 1 | CANpassive error on IF1 |
| 2 | CANbusoff | 0 | No error |
| | | 1 | CANbusoff error on IF1 |
| 3 | CANRXoverrun | 0 | No error |
| | | 1 | CANRXoverrun error on IF1 |
| 4 - 7 | Reserved | - | |

CANwarning

A faulty frame was detected on the CAN bus. This can include bit errors, bit stuffing errors, CRC errors, format errors in the telegram and acknowledgment errors, for example.

CANpassive

The internal transmit and/or receive error counter is greater than 127. CAN communication continues to run, but the interface can only issue a "passive error frame". Likewise, "error passive stations" have less ability to send new telegrams altogether.

CANbusoff

The internal transmit error counter is greater than 255. The bus is switched off, and CAN communication with the module no longer takes place.

CANRXoverrun

An overflow occurred in the module's receive buffer.

9.18.7.8.9.2 CAN error acknowledgment

Name:

CAN error acknowledgment

Setting the bits in this register acknowledges the error assigned to the bit and clears the corresponding bit in the "CAN error status" register. The application thus informs the module that it has recognized the error state.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------|-------|---------------------------------------|
| 0 | QuitCANwarning | 0 | No acknowledgment |
| | | 1 | Acknowledge CANwarning error on IF1 |
| 1 | QuitCANpassive | 0 | No acknowledgment |
| | | 1 | Acknowledge CANpassive error on IF1 |
| 2 | QuitCANbusoff | 0 | No acknowledgment |
| | | 1 | Acknowledge CANbusoff error on IF1 |
| 3 | QuitCANRXoverrun | 0 | No acknowledgment |
| | | 1 | Acknowledge CANRXoverrun error on IF1 |
| 4 - 7 | Reserved | - | |

9.18.7.8.9.3 New CAN telegram for transmit buffer

Name:

TXCount

By increasing this value, the application notifies the module that a new CAN telegram should be transferred into the transmit buffer.

| Data type | Value |
|-----------|----------|
| USINT | 0 to 255 |

9.18.7.8.9.4 Read "TXCount"

Name:

TXCountReadBack

The value of "TXCount" is copied from the module into this register. This makes it possible for the application task to verify that the CAN telegram data was transferred from the module correctly.

The meaning of the value depends on the "TxFifoInfo" bit. This is located in the register "Cfo_TXRXinfoFlags" on page 2187.

| Data type | Value | "TxFifoInfo" bit | Meaning |
|-----------|----------|------------------|----------------------|
| USINT | 0 to 255 | 0 | Read back "TX-Count" |
| | | 1 | See bit structure. |

Bit structure:

| Bit | Function | Value | Information |
|-------|--|---------|---|
| 0 - 3 | Read back "TX-Count" | 0 to 15 | Only the lower 4 bits |
| 4 - 7 | Number of frames in the transmit buffer that have not been transmitted | 0 to 15 | If this number exceeds the 15 (a maximum of 18 possible), the value 15 is returned. |

9.18.7.8.9.5 Read "TXCount" from the previous cycle

Name:

TXCountLatchReadBack

This register is used to copy the "TXCount" value from the previous cycle from the module. In the event of an X2X Link or POWERLINK transfer error, this makes it possible to determine if the error occurred on the way from the CPU to the module or on the way from the module to the CPU (see "Taking possible errors into consideration when transmitting" on page 2191).

The meaning of the value depends on the "TxFifoInfo" bit in the "Cfo_TXRXinfoFlags" on page 2187 register.

| Data type | Value | "TxFifoInfo" bit | Meaning |
|-----------|----------|------------------|--|
| USINT | 0 to 255 | 0 | TX-Count read back from the previous cycle |
| | | 1 | See bit structure. |

Bit structure:

| Bit | Function | Value | Information |
|-------|--|---------|-------------------------|
| 0 - 3 | TX-Count read back from the previous cycle | 0 to 15 | Only the lower 4 bits |
| 4 - 7 | Number of frames in the transmit buffer that have not been transmitted | 0 to 15 | From the previous cycle |

9.18.7.8.9.6 Counter for received CAN telegrams

Name:

RXCount

This counter is increased by 1 with each CAN telegram. The application task can thus detect when new data is received and get it from the corresponding "RXData" registers.

The meaning of the value depends on the "RxFifoInfo" on page 2187 bit in the "Cfo_TXRXinfoFlags" register.

| Data type | Value | "RxFifoInfo" bit | Meaning |
|-----------|----------|------------------|--------------------------------|
| USINT | 0 to 255 | 0 | Counter for received telegrams |
| | | 1 | See bit structure. |

Bit structure:

| Bit | Function | Value | Information |
|-------|--|---------|-----------------------|
| 0 - 3 | Counter for received telegrams | 0 to 15 | Only the lower 4 bits |
| 4 - 7 | Number of unacknowledged telegrams in the receive buffer | 0 to 15 | |

9.18.7.8.9.7 Read "RXCount" from the previous cycle

Name:

RXCountLatch

This register always contains the "RXCount" value from the previous cycle. It can be used to detect transfer errors from the module to the CPU (see ["Taking possible errors into consideration when transmitting" on page 2191](#)).

The meaning of the value depends on the RxFifoInfo bit in the ["Cfo_TXRXinfoFlags" on page 2187](#) register.

| Data type | Value | "RxFifoInfo" bit | Meaning |
|-----------|----------|------------------|--|
| USINT | 0 to 255 | 0 | Counter for received telegrams from the previous cycle |
| | | 1 | See bit structure. |

Bit structure:

| Bit | Function | Value | Information |
|-------|---|---------|-----------------------|
| 0 - 3 | Counter for received telegrams from the previous cycle | 0 to 15 | Only the lower 4 bits |
| 4 - 7 | Number of telegrams in the receive buffer from the previous cycle | 0 to 15 | |

9.18.7.8.10 Send buffer

9.18.7.8.10.1 Number of CAN payload data bytes

Name:

TXDataSize

Number of CAN payload data bytes to be transmitted. If a value less than 0 is specified here, this CAN telegram is marked as being invalid and is not transferred into the transmit buffer. This is useful in connection with transmit error detection between the module and the CPU (see ["Taking possible errors into consideration when transmitting" on page 2191](#)).

| Data type | Value | Meaning |
|-----------|-----------|---|
| USINT | -128 to 8 | Amount of CAN payload data to be transmitted. |

9.18.7.8.10.2 Identifier of the CAN telegram to be transmitted.

Name:

TXIdent

Identifier of the CAN telegram to be transmitted. The frame format and the identifier format are also defined in this register.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|--|
| 0 | Frame format | 0 | Standard frame format (SFF) with an 11-bit identifier |
| | | 1 | Extended frame format (EFF) with an 29-bit identifier |
| 1 | Frame type | 0 | Data frame |
| | | 1 | Remote frame (RTR) |
| 2 | Reserved | - | |
| 3 - 31 | CAN identifier for telegram to be transmitted | x | Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits ¹⁾ |

1) Only bits 21 to 31 are used; bits 3 to 20 = 0.

9.18.7.8.10.3 Configuration of the CAN payload data being sent

Name:

TXDataByte0 to TXDataByte7

TXDataWord0 to TXDataWord3

TXDataLong0 to TXDataLong1

CAN payload data in the transmit direction. The 8 payload data bytes for a telegram can be used as data points with 8 individual bytes, 4 words or 2 longs as needed.

| Data type | Value | Description |
|-----------|--------------------|---------------------------------------|
| USINT | 0 to 255 | CAN payload data transmitted as bytes |
| UINT | 0 to 65,535 | CAN payload data transmitted as words |
| UDINT | 0 to 4.294.967.295 | CAN payload data transmitted as longs |

9.18.7.8.10.4 Taking possible errors into consideration when transmitting

Data on the POWERLINK network or X2X Link can be lost due to transmission errors. One-time failures of cyclic data are tolerated by the I/O systems. This is possible since all I/O data is re-transferred in the subsequent cycle. A transfer error cannot be detected from the I/O variables; they remain frozen on the value from the last cycle.

These tolerated one-time I/O failures can lead to data loss or the delayed CAN telegram transmission. The counter feedback is derived on the module and used to detect these cases.

Register for counter feedback:

- ["TXCountReadBack" on page 2189](#)
- ["TXCountLatchReadBack" on page 2189](#)

9.18.7.8.11 Receive buffers 0 and 1

9.18.7.8.11.1 Number of valid CAN payload data bytes

Name:
RXDataSize0
RXDataSize1

Number of valid CAN payload data bytes.

This register also uses the value -1 (0xFF) to indicate a general error or gap in the input data stream. Details regarding the error that has occurred can be seen in the ["CAN error status" on page 2188](#) register.

| Data type | Value | Meaning |
|-----------|--------|-------------------------|
| USINT | 1 to 8 | Number CAN payload data |
| | -1 | Error |

9.18.7.8.11.2 Identifier of the received data

Name:
RXIdent0
RXIdent1

Identifiers assigned to the received data. The frame format and the identifier format can also be read from this register.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|--|
| 0 | Frame format | 0 | Standard frame format (SFF) with an 11-bit identifier |
| | | 1 | Extended frame format (EFF) with an 29-bit identifier |
| 1 | Frame type | 0 | Data frame |
| | | 1 | Remote frame (RTR) |
| 2 | Reserved | - | |
| 3 - 31 | CAN identifier for telegram to be transmitted | x | Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits ¹⁾ |

1) Only bits 21 to 31 are used; bits 3 to 20 = 0.

9.18.7.8.11.3 Configuration of the CAN payload data to be received

Name:
RXData0Byte0 to RXData0Byte7
RXData0Word0 to RXData0Word3
RXData0Long0 to RXData0Long1

RXData1Byte0 to RXData1Byte7
RXData1Word0 to RXData1Word3
RXData1Long0 to RXData1Long1

These registers hold the payload data of the CAN object to be transferred from the receive buffer to the CPU in the current cycle. If new data is received or if the receive buffer contains additional CAN objects, these registers are overwritten with the new data in the next cycle.

To avoid losing CAN objects, the application must respond immediately to a change in the "RXCount" and copies the data from these registers.

The maximum 8 bytes for a CAN telegram can be used as data points with 8 individual bytes, 4 words or 2 longs as needed.

| Data type | Value | Description |
|-----------|--------------------|------------------------------------|
| USINT | 0 to 255 | Received CAN payload data as bytes |
| UINT | 0 to 65,535 | Received CAN payload data as words |
| UDINT | 0 to 4.294.967.295 | Received CAN payload data as longs |

9.18.7.8.12 Flatstream communication

For a description of Flatstream communication, see ["Flatstream communication" on page 3802](#)

9.18.7.8.13 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.

Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

| Data type | Value | Information |
|-----------|---------|---|
| - | 8 to 28 | Acyclic frame size in bytes. Default = 24 |

9.18.7.8.14 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 μ s |

9.18.7.8.15 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 200 μ s |

9.18.8 X20CS2770

Data sheet version: 3.28

9.18.8.1 General information

In addition to the standard I/O, complex devices often need to be connected. The X20 CS communication modules are intended precisely for cases like this. As normal X20 electronics modules, they can be placed anywhere on the remote backplane.

- 2 CAN bus interfaces for serial, remote connection of complex devices to the X20 system
- Integrated terminating resistors

9.18.8.2 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | X20 electronics module communication |  |
| X20CS2770 | X20 interface module, 2 CAN bus interfaces, max. 1 Mbit/s, object buffers in both send and receive directions | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |
| | Terminal blocks | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |

Table 393: X20CS2770 - Technical data

9.18.8.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|--------|--------|--|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | Single flash | I/O error occurred <ul style="list-style-type: none"> • CAN bus: Warning, passive or off • Buffer overflow |
| | | | On | Error or reset status |
| | e + r | | Red on / Green single flash | Invalid firmware |
| | Tx1/2 | Yellow | On | The module is sending data via the CAN bus interface IF1/IF2 |
| Rx1/2 | Yellow | On | The module is receiving data via the CAN bus interface IF1/IF2 | |
| T1/2 | Yellow | On | The integrated terminating resistor for the CAN bus interface IF1/IF2 is turned on | |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.18.8.5 Pinout

9.18.8.6 Terminating resistors

Two terminating resistors are integrated in the communication module. The respective resistor can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "T1" or "T2" LED.

9.18.8.7 Derating

There is no derating when operated below 55°C.

During operation over 55°C, the power dissipation of the modules to the left and right of this module is not permitted to exceed 1.15 W!

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

| | | | | | | |
|-------|--|--|-------------|--|--|-------|
| | X20 module Power dissipation > 1.15 W | Neighboring X20 module Power dissipation ≤ 1.15 W | This module | Neighboring X20 module Power dissipation ≤ 1.15 W | X20 module Power dissipation > 1.15 W | |
|-------|--|--|-------------|--|--|-------|

9.18.8.8 Register description

9.18.8.8.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.18.8.8.2 Function model 0 - Flat

In the "Flat" function model, CAN information is transferred via cyclic input and output registers. All data for a CAN object (8 CAN data bytes, identifier, status, etc.) is accessible as individual data points (see also ["CAN object" on page 2202](#)).

To transmit a CAN object, the CAN identifier, the CAN data (max. 8 bytes) and the number of bytes to be transmitted must be written to the cyclic I/O data points. Then, "TX0[x]Count" is increased to send the transmission. The data is held in the module's internal buffer (max. 18 objects) and transmitted over the CAN network at the next available opportunity.

Receiving information from the CAN network uses the same algorithm. The module saves the CAN messages in its internal buffer along with the respective identifiers. Then the CAN identifier, the CAN data (max. 8 bytes) and the number of bytes to be processed are written to the cyclic I/O data points. RX0[x]Count tells the application how much new data must be taken from these input data points.

Information:

- Libraries "ArCAN" and "CAN_Lib" cannot be used.

| Register | Name | Data type | Read | | Write | |
|----------------------------------|--------------------------------|-----------|--------|------------|--------|------------|
| | | | Cyclic | Non-cyclic | Cyclic | Non-cyclic |

9.18.8.8.3 Function model 2 - Stream and Function model 254 - Cyclic stream

Function models "Stream" and "Cyclic stream" use a module-specific driver of the CPU's operating system. The interface can be controlled using libraries "ArCAN" and "CAN_Lib" and reconfigured at runtime.

Function model - Stream

In function model "Stream", the CPU communicates with the module acyclically. The interface is relatively convenient, but the timing is very imprecise.

Function model - Cyclic stream

Function model "Cyclic stream" was implemented later. From the application's point of view, there is no difference between function models "Stream" and "Cyclic stream". Internally, however, the cyclic I/O registers are used to ensure that communication follows deterministic timing.

Information:

- In order to use function models "Stream" and "Cyclic stream", you must be using B&R controllers of type "SG4".
- These function models can only be used in X2X Link and POWERLINK networks.

| Register | Name | Data type | Read | | Write | |
|----------------------------------|--------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |

| | QuitCANIF2busoff | Bit 6 | | | | |
| QuitCANIF2RXoverrun | Bit 7 | | | | | |

9.18.8.8.4 Function model 254 - Flatstream

Flatstream provides independent communication between an X2X Link master and the module. This interface was implemented as a separate function model for the CAN module. CAN information (identifier, status, etc.) is transferred via cyclic input and output registers. The sequence and control bytes are used to control this data stream (see "Flatstream communication" on page 3802).

When using function model Flatstream, the user can choose whether to use library "AsFltGen" in AS for implementation or to adapt Flatstream handling directly to the individual requirements of the application.

Information:

- Libraries "ArCAN" and "CAN_Lib" cannot be used.
- Higher data rates can be achieved between X2X master and module compared to the "Flat" function model.

| Register | Name | Data type | Read | | Write | |

9.18.8.8.5 Function model 254 - Bus controller

The "Bus controller" function model is a reduced form of the "FlatStream" function model. Instead of up to 27 Tx / Rx bytes, a maximum of 7 Tx / Rx bytes can be used.

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |

| Index * 1 + 96 | Index * 1 + 8 | Tx02Byte1 to Tx02Byte7 | USINT | | | • | |

1) The offset specifies the position of the register within the CAN object.

9.18.8.8.5.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.18.8.8.5.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.18.8.8.6 Using this module with SGC target systems

Information:

This module can only be used with SGC target systems if the function model is set to "Flatstream" or "Flat".

9.18.8.8.7 CAN object

A CAN object is always made up of a 4-byte identifier and a maximum of 8 subsequent data bytes. This also results in the relationship between CAN object length and the amount of CAN payload data. This is important because the number of CAN payload data bytes for communication via "FlatStream" always has to be determined using the frame length.

Composition of a CAN object / CAN frame

| Bytes | Function | Information |
|--------|------------------|-------------------------------|
| 1 | Code | ID bit 0 to 7 |
| 2 | | ID bit 8 to 15 |
| 3 | | ID bit 16 to 23 |
| 4 | | ID bit 24 to 31 |
| 5 - 12 | CAN payload data | 0 to 8 CAN payload data bytes |

Code

The 32 bits (4 bytes) of the CAN identifier are used as follows:

| Bit | Description | Value | Information |
|--------|---|-------|--|
| 0 | Frame format | 0 | Standard frame format (SFF) with an 11-bit identifier |
| | | 1 | Extended frame format (EFF) with an 29-bit identifier |
| 1 | Frame type | 0 | Data frame |
| | | 1 | Remote frame (RTR) |
| 2 | Reserved | - | |
| 3 - 31 | CAN identifier for telegram to be transmitted | x | Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits ¹⁾ |

1) Only bits 21 to 31 are used; bits 3 to 20 = 0.

9.18.8.8.7.1 CAN module data stream

In function model 254, the data packets to be transferred in a data stream are referred to as frames.

Information:

For the CAN module, that means:

- A frame always contains one CAN object and therefore cannot be longer than 12 bytes.
- The CAN object is only transferred to the transmit buffer after the frame has been completed.
- The CAN payload data length has a fixed relationship with the frame length and the actual size of the CAN object. The following rules apply:
 - CAN payload data length = Frame length - 4
 - Frame length = CAN payload data length + 4

9.18.8.8.8 Interface - Configuration

9.18.8.8.8.1 Transfer rate

Name:

Config01Baudrate to Config02Baudrate

"Baud rate" in the Automation Studio I/O configuration.

Configuration of the CAN transfer rate for the respective interface.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------|-------|---|
| 0 - 3 | Transfer rate | 0 | Interface disabled (bus controller default setting) |
| | | 1 | 10 kbit/s |
| | | 2 | 20 kbit/s |
| | | 3 | 50 kbit/s |
| | | 4 | 100 kbit/s |
| | | 5 | 125 kbit/s |
| | | 6 | 250 kbit/s |
| | | 7 | 500 kbit/s |
| | | 8 | 800 kbit/s |
| | | 9 | 1000 kbit/s |
| 4 - 7 | Reserved | - | |

9.18.8.8.8.2 Synchronization Jump Width

Name:

Config01SJW to Config02SJW

"Synchronization jump width" in the Automation Studio I/O configuration.

The synchronization jump width (SJW) is used to resynchronize the sample point within a CAN telegram.

A detailed description of the SJW can be found in the CAN specification.

| Data type | Value | Meaning |
|-----------|--------|--|
| USINT | 0 to 4 | Synchronization jump width. Bus controller default setting: 3 |

9.18.8.8.8.3 Offset for the sampling instant

Name:

Config01SPO to Config02SPO

"Sample point offset" in the Automation Studio I/O configuration.

Offset for the sample point of the individual bits on the CAN bus.

A detailed description of the SPO can be found in the CAN specification.

| Data type | Value | Meaning |
|-----------|--------|---|
| USINT | 0 to 1 | Sample point offset. Bus controller default setting: 0 |

9.18.8.8.8.4 Start of transmission

Name:

Config01TXtrigger to Config02TXtrigger

"TX objects / TX triggers" in the Automation Studio I/O configuration.

Defines the number of CAN objects that must be copied to the transmit buffer before the transmission is started.

| Data type | Value | Meaning |
|-----------|--------|---|
| UINT | 0 to 8 | Number of CAN objects in the transmit buffer before transmission is started. Bus controller default setting: 1 |

9.18.8.8.5 Configuration of error messages

Name:

Cfo_ErrorID0007

This register must be used first to configure the error messages that have to be transferred. If the corresponding enable bit is not set, no error status will be sent to the higher-level system when the error occurs.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------|-------|---|
| 0 | CANIF1warning | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 1 | CANIF1passive | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 2 | CANIF1bussoff | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 3 | CANIF1RXoverrun | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 4 | CANIF2warning | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 5 | CANIF2passive | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 6 | CANIF2bussoff | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |
| 7 | CANIF2RXoverrun | 0 | Disabled (bus controller default setting) |
| | | 1 | Enabled |

9.18.8.8.6 Size of the transmit buffer

Name:

Cfo_FIFOTXlimit01 to Cfo_FIFOTXlimit02

"TX FIFO size" in the Automation Studio I/O configuration.

Determines the size of the transmit buffer for the respective interface.

| Data type | Value | Meaning |
|-----------|---------|-----------------------------|
| USINT | 0 to 18 | Size of the transmit buffer |

9.18.8.8.7 Display of unprocessed elements remaining in transmit/receive buffer

Name:

Cfo_TXRXinfoFlags01 to Cfo_TXRXinfoFlags02

This register can be used to specify that the number of unprocessed elements in the transmit and receive buffers is indicated in the upper 4 bits of the "TX0[x]CountReadBack" and "RX0[x]Count" registers for the respective interface.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|---|
| 0 | TxFifoInfo "Mode of channel TX0[x]CountReadBack" in the Automation Studio I/O configuration | 0 | The "TX0[x]Count" is read in the "TX0[x]CountReadBack" on page 2206 register. |
| | | 1 | The "TX0[x]Count" is read in the "TX0[x]CountReadBack" on page 2206 register. The upper 4 bits are used to return the number of frames in the transmit buffer that have not been transmitted. |
| 1 | RxFifoInfo "Mode of channel RX0[x]Count" in the Automation Studio I/O configuration | 0 | The number of received telegrams is shown in the "RX0[x]Count" on page 2207 register. |
| | | 1 | The number of received telegrams is shown in the lower 4 bits of the "RX0[x]Count" on page 2207 register. The upper 4 bits are used to indicate the number of received but not acknowledged telegrams in the receive buffer. |
| 2 - 7 | Reserved | - | |

9.18.8.8.9 Interface - Communication

9.18.8.8.9.1 CAN error status

Name:

CAN error status

The bits in this register indicate the error states defined in the CAN protocol. If an error occurs, the corresponding bit is set. For an error bit to be reset, the corresponding bit must be acknowledged (see "[CAN error acknowledgment](#)" on page 2206).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------|-------|--|
| 0 | CANIF1warning | 0 | No error |
| | | 1 | CANwarning Error occurred on IF1 |
| 1 | CANIF1passive | 0 | No error |
| | | 1 | CANpassive Error occurred on IF1 |
| 2 | CANIF1busoff | 0 | No error |
| | | 1 | CANbusoff Error occurred on IF1 |
| 3 | CANIF1RXoverrun | 0 | No error |
| | | 1 | CANRXoverrun Error occurred on IF1 |
| 4 | CANIF2warning | 0 | No error |
| | | 1 | CANwarning Error occurred on IF2 |
| 5 | CANIF2passive | 0 | No error |
| | | 1 | CANpassive Error occurred on IF2 |
| 6 | CANIF2busoff | 0 | No error |
| | | 1 | CANbusoff Error occurred on IF2 |
| 7 | CANIF2RXoverrun | 0 | No error |
| | | 1 | CANRXoverrun Error occurred on IF2 |

CANwarning

A faulty frame was detected on the CAN bus. This can include bit errors, bit stuffing errors, CRC errors, format errors in the telegram and acknowledgment errors, for example.

CANpassive

The internal transmit and/or receive error counter is greater than 127. CAN communication continues to run, but the interface can only issue a "passive error frame". Likewise, "error passive stations" have less ability to send new telegrams altogether.

CANbusoff

The internal transmit error counter is greater than 255. The bus is switched off, and CAN communication with the module no longer takes place.

CANRXoverrun

An overflow occurred in the module's receive buffer.

9.18.8.8.9.2 CAN error acknowledgment

Name:

CAN error acknowledgment

Setting the bits in this register acknowledges the error assigned to the bit and clears the corresponding bit in the "CAN error status" register. The application thus informs the module that it has recognized the error state.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|---------------------|-------|---------------------------------------|
| 0 | QuitCANIF1warning | 0 | No acknowledgment |
| | | 1 | Acknowledge CANwarning error on IF1 |
| 1 | QuitCANIF1passive | 0 | No acknowledgment |
| | | 1 | Acknowledge CANpassive error on IF1 |
| 2 | QuitCANIF1bussoff | 0 | No acknowledgment |
| | | 1 | Acknowledge CANbussoff error on IF1 |
| 3 | QuitCANIF1RXoverrun | 0 | No acknowledgment |
| | | 1 | Acknowledge CANRXoverrun error on IF1 |
| 4 | QuitCANIF2warning | 0 | No acknowledgment |
| | | 1 | Acknowledge CANwarning error on IF2 |
| 5 | QuitCANIF2passive | 0 | No acknowledgment |
| | | 1 | Acknowledge CANpassive error on IF2 |
| 6 | QuitCANIF2bussoff | 0 | No acknowledgment |
| | | 1 | Acknowledge CANbussoff error on IF2 |
| 7 | QuitCANIF2RXoverrun | 0 | No acknowledgment |
| | | 1 | Acknowledge CANRXoverrun error on IF2 |

9.18.8.8.9.3 New CAN telegram for transmit buffer

Name:

TX01Count to TX02Count

By increasing this value, the application notifies the module that a new CAN telegram should be transferred into the transmit buffer.

| Data type | Value |
|-----------|----------|
| USINT | 0 to 255 |

9.18.8.8.9.4 Read "TX0[x]Count"

Name:

TX01CountReadBack to TX02CountReadBack

The value of "TX0[x]Count" is copied from the module into this register. This makes it possible for the application task to verify that the CAN telegram data was transferred from the module correctly.

The meaning of the value depends on the "TxFifoInfo" bit. This is located in the register "[Cfo_TXRXinfoFlags0\[x\]](#)" on [page 2204](#).

| Data type | Value | "TxFifoInfo" bit | Meaning |
|-----------|----------|------------------|--------------------|
| USINT | 0 to 255 | 0 | Read "TX0[x]Count" |
| | | 1 | See bit structure. |

Bit structure:

| Bit | Function | Value | Information |
|-------|--|---------|---|
| 0 - 3 | Read "TX0[x]Count" | 0 to 15 | Only the lower 4 bits |
| 4 - 7 | Number of frames in the transmit buffer that have not been transmitted | 0 to 15 | If this number exceeds the 15 (a maximum of 18 possible), the value 15 is returned. |

9.18.8.8.9.5 Counter for received CAN telegrams

Name:

RX01Count to RX02Count

This counter is increased by 1 with each CAN telegram. The application task can thus detect when new data is received and get it from the corresponding "RX0[x]Data" registers.

The meaning of the value depends on the "Cfo_TXRXinfoFlags0[x]" on page 2204 bit in the "Cfo_TXRXinfoFlags" register.

| Data type | Value | "RxFifoInfo" bit | Meaning |
|-----------|----------|------------------|--------------------------------|
| USINT | 0 to 255 | 0 | Counter for received telegrams |
| | | 1 | See bit structure. |

Bit structure:

| Bit | Function | Value | Information |
|-------|--|---------|-----------------------|
| 0 - 3 | Counter for received telegrams | 0 to 15 | Only the lower 4 bits |
| 4 - 7 | Number of unacknowledged telegrams in the receive buffer | 0 to 15 | |

9.18.8.8.10 Transmit buffer for IF1 and IF2**9.18.8.8.10.1 Number of CAN payload data bytes**

Name:

TX01DataSize to TX02DataSize

Number of CAN payload data bytes to be transmitted. If a value less than 0 is specified here, this CAN telegram is marked as being invalid and is not transferred into the transmit buffer. This is useful in connection with transmit error detection between the module and the CPU (see ["Taking possible errors into consideration when transmitting" on page 2208](#)).

| Data type | Value | Meaning |
|-----------|-----------|--|
| USINT | -128 to 8 | Amount of CAN payload data to be transmitted |

9.18.8.8.10.2 Identifier of the CAN telegram to be transmitted.

Name:

TX01Ident to TX02Ident

Identifier of the CAN telegram to be transmitted. The frame format and the identifier format are also defined in this register.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|--|
| 0 | Frame format | 0 | Standard frame format (SFF) with an 11-bit identifier |
| | | 1 | Extended frame format (EFF) with an 29-bit identifier |
| 1 | Frame type | 0 | Data frame |
| | | 1 | Remote frame (RTR) |
| 2 | Reserved | - | |
| 3 - 31 | CAN identifier for telegram to be transmitted | x | Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits ¹⁾ |

1) Only bits 21 to 31 are used; bits 3 to 20 = 0.

9.18.8.8.10.3 Configuration of the CAN payload data being sent

Name:

TX0[x]DataByte0 to TX0[x]DataByte7

TX0[x]DataWord0 to TX0[x]DataWord3

TX0[x]DataLong0 to TX0[x]DataLong1

CAN payload data in the transmit direction. The 8 payload data bytes for a telegram can be used as data points with 8 individual bytes, 4 words or 2 longs as needed.

| Data type | Value | Description |
|-----------|--------------------|---------------------------------------|
| USINT | 0 to 255 | CAN payload data transmitted as bytes |
| UINT | 0 to 65,535 | CAN payload data transmitted as words |
| UDINT | 0 to 4.294.967.295 | CAN payload data transmitted as longs |

9.18.8.8.10.4 Taking possible errors into consideration when transmitting

Data on the POWERLINK network or X2X Link can be lost due to transmission errors. One-time failures of cyclic data are tolerated by the I/O systems. This is possible since all I/O data is re-transferred in the subsequent cycle. A transfer error cannot be detected from the I/O variables; they remain frozen on the value from the last cycle.

These tolerated one-time I/O failures can lead to data loss or the delayed CAN telegram transmission. The counter feedback is derived on the module and used to detect these cases.

Register for counter feedback: ["TX0\[x\]CountReadBack" on page 2206](#)

9.18.8.8.11 Receive buffer for IF1 and IF2

9.18.8.8.11.1 Number of valid CAN payload data bytes

Name:

RX01DataSize to RX02DataSize

Number of valid CAN payload data bytes.

This register also uses the value -1 (0xFF) to indicate a general error or gap in the input data stream. Details regarding the error that has occurred can be seen in the ["CAN error status" on page 2205](#) register.

| Data type | Value | Meaning |
|-----------|--------|-------------------------|
| USINT | 1 to 8 | Number CAN payload data |
| | -1 | Error |

9.18.8.8.11.2 Identifier of the received data

Name:

RX01Ident to RX02Ident

Identifiers assigned to the received data. The frame format and the identifier format can also be read from this register.

| Data type | Values |
|-----------|------------------------|
| UDINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|--|
| 0 | Frame format | 0 | Standard frame format (SFF) with an 11-bit identifier |
| | | 1 | Extended frame format (EFF) with an 29-bit identifier |
| 1 | Frame type | 0 | Data frame |
| | | 1 | Remote frame (RTR) |
| 2 | Reserved | - | |
| 3 - 31 | CAN identifier for telegram to be transmitted | x | Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits ¹⁾ |

1) Only bits 21 to 31 are used; bits 3 to 20 = 0.

9.18.8.8.11.3 Configuration of the CAN payload data to be received

Name:

RX0[x]DataByte0 to RX0[x]DataByte7

RX0[x]DataWord0 to RX0[x]DataWord3

RX0[x]DataLong0 to RX0[x]DataLong1

These registers hold the payload data of the CAN object to be transferred from the receive buffer to the CPU in the current cycle. If new data is received or if the receive buffer contains additional CAN objects, these registers are overwritten with the new data in the next cycle.

To avoid losing CAN objects, the application must respond immediately to a change in the "RX0[x]Count" and copies the data from these registers.

The maximum 8 bytes for a CAN telegram can be used as data points with 8 individual bytes, 4 words or 2 longs as needed.

| Data type | Value | Description |
|-----------|--------------------|------------------------------------|
| USINT | 0 to 255 | Received CAN payload data as bytes |
| UINT | 0 to 65,535 | Received CAN payload data as words |
| UDINT | 0 to 4.294.967.295 | Received CAN payload data as longs |

9.18.8.8.12 Flatstream communication

For a description of Flatstream communication, see ["Flatstream communication" on page 3802](#)

9.18.8.8.13 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.

Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

| Data type | Value | Information |
|-----------|---------|---|
| - | 8 to 28 | Acyclic frame size in bytes. Default = 24 |

9.18.8.8.14 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 200 µs |

9.18.8.8.15 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 200 µs |

9.19 Expandable bus controllers

On expandable bus controllers, up to 2 interface or hub expansion modules can be connected depending on the bus module being used.

Compact design

The supply for the bus controller, X2X Link network and I/O modules is part of the bus controller. No additional power supply modules are required.

9.19.1 Summary

| Model number | Short description | Page |
|--------------|---|------|
| X20BC1083 | X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, supports X20 interface module expansions, 2 RJ45, order bus base, power supply module and terminal block separately | 2213 |
| X20BC8083 | X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, supports expansion with X20 hub modules, 2 RJ45, order bus base, power supply module and terminal block separately. | 2220 |
| X20BC8084 | X20 bus controller, 1 POWERLINK interface, 1x link selector for POWERLINK cable redundancy, supports expansion with enabled X20 hub modules, 2x RJ45, order bus base, power supply module and terminal block separately! | 2227 |
| X20cBC1083 | X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, supports X20 interface module expansions, 2 RJ45, order bus base, power supply module and terminal block separately | 2213 |
| X20cBC8083 | X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, supports X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately | 2220 |
| X20cBC8084 | X20 bus controller, coated, 1 POWERLINK interface, 1x link selector for POWERLINK cable redundancy, supports expansion with active X20 hub modules, 2x RJ45, order bus base, power supply module and terminal block separately! | 2227 |

9.19.2 X20(c)BC1083

Data sheet version: 2.49

9.19.2.1 General information

The bus controller makes it possible to connect X2X Link I/O nodes to POWERLINK. It is also possible to operate the X2X Link cycle synchronously 1:1 or synchronous to POWERLINK using a prescaler.

POWERLINK is a standard protocol for Fast Ethernet with hard real-time characteristics. The POWERLINK Standardization Group (EPSG) ensures openness and continuous advancement. www.ethernet-powerlink.org

The bus modules expanded to the left allow connection of up to 2 interface modules in addition to the bus controller.

- POWERLINK
- I/O configuration and firmware update via the fieldbus
- Integrated hub for efficient cabling
- Up to 2 slots for interface modules

9.19.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.19.2.2.1 Starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C . During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.19.2.3 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | Expandable bus controllers |  |

Table 395: X20BC1083, X20cBC1083 - Technical data

- 1) See Automation Help under "Communication / POWERLINK / General information / Hardware - CN" for more information.
- 2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
- 3) Spacing is based on the width of the X20BB81 or X20BB82 bus base. Up to 2 interfaces modules and 1 X20PS9400 or X20PS9402 supply module are also always required for the bus controller.

9.19.2.5 Operating and connection elements

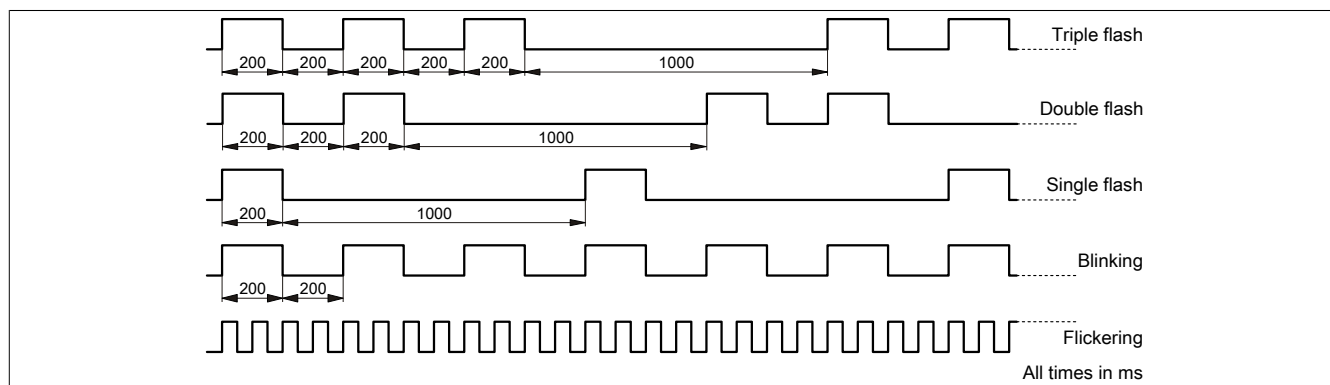

9.19.2.5.1 LED status indicators

| Figure | LED | Color | Status | Description | |
|---|-------------------|---------|--------------|--|---|
|  | S/E ¹⁾ | Green | Off | No power supply or mode NOT_ACTIVE. The controlled node (CN) is either not supplied with power, or it is in state NOT_ACTIVE. The CN waits in this state for about 5 seconds after a restart. Communication is not possible with the CN. If no POWERLINK communication is detected during these 5 seconds, the CN enters state BASIC_ETHERNET (flickering). If POWERLINK communication is detected before this time expires, however, the CN immediately enters state PRE_OPERATIONAL_1. | |
| | | | Flickering | Mode BASIC_ETHERNET. The CN has not detected any POWERLINK communication. In this state, it is possible to communicate directly with the CN (e.g. with UDP, IP, etc.) If communication POWERLINK is detected in this state, the CN switches to PRE_OPERATIONAL_1. | |
| | | | Single flash | Mode PRE_OPERATIONAL_1. When operating on a POWERLINK V1 manager, the CN switches directly to PRE_OPERATIONAL_2. When operated on a POWERLINK V2 manager, the CN waits until an SoC frame is received and then switches to the PRE_OPERATIONAL_2 state. | |
| | | | Double flash | Mode PRE_OPERATIONAL_2. The CN is normally configured by the manager in this state. It is then switched to state READY_TO_OPERATE by command (POWERLINK V2) or by setting the "data valid" flag in the output data (POWERLINK V1). | |
| | | | Triple flash | Mode READY_TO_OPERATE. In network POWERLINK V1, the CN switches automatically to OPERATIONAL as soon as input data is present. In a POWERLINK V2 network, the manager switches to the OPERATIONAL state by issuing a command. | |
| | | | On | Mode OPERATIONAL. The PDO mapping is active and cyclic data is evaluated. | |
| | | | Blinking | Mode STOPPED. Output data is not being output, and no input data is being provided. It is only possible to switch to or leave this state after the manager has given the appropriate command. | |
| | | | Red | On | The controlled node (CN) is in an error state (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: <ul style="list-style-type: none"> • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  <p>Note:</p> <ul style="list-style-type: none"> • Several red blinking signals are displayed immediately after the device is switched on. This is not an error, however. • The LED is lit red for CNs with configured physical node number 0 but that have not yet been assigned a node number via dynamic node allocation (DNA). |
| | | L/A IFx | Green | On | Link established to the remote station |
| | | | | | Blinking |

1) The Status/Error LED "S/E" is a green/red dual LED.

Status-LEDs - Blinkzeiten

9.19.2.5.2 POWERLINK node number

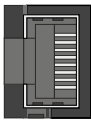

The node number for the POWERLINK node is set using the two number switches.

| Switch position | Description |
|-----------------|--|
| 0x00 | Only permitted when operating the POWERLINK node in DNA mode. |
| 0x01 - 0xEF | Node number of the POWERLINK node. Operation as a controlled node. |
| 0xF0 - 0xFF | Reserved, switch position not permitted. |

9.19.2.5.3 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see ["Cabling guidelines for X20 modules with an Ethernet cable" on page 58](#).

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.19.2.5.4 Slot for interface modules

Depending on the bus base, up to two interface modules can be installed on the left side of the expandable bus controller:

| Bus base | Slots for interface modules |
|----------|-----------------------------|
| X20BB81 | 1 |
| X20BB82 | 2 |

Table 396: Slots for interface modules for various bus bases

9.19.2.6 Dynamic node allocation (DNA)

Most POWERLINK bus controllers have the ability to dynamically assign node numbers. This has the following advantages:

- No setting of the node number switch
- Easier installation
- Reduced error sources

For information regarding configuration as well as an example, see Automation Help → Communication → POWERLINK → General information → Dynamic node allocation (DNA)

Information:

Interface IF1 must always be used as the input from the preceding node.

9.19.2.7 Operating netX modules with bus controller X20BC1083

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.19.2.8 SG3

This module is not supported on SG3 target systems.

9.19.2.9 SG4

The module comes with preinstalled firmware. The firmware is also part of the Automation Runtime operating system for the PLC. With different versions, the Automation Runtime firmware is loaded onto the module.

The latest firmware is made available automatically when updating Automation Runtime.

9.19.3 X20(c)BC8083

Data sheet version: 2.39

9.19.3.1 General information

The bus controller makes it possible to connect X2X Link I/O nodes to POWERLINK. It is also possible to operate the X2X Link cycle synchronously 1:1 or synchronous to POWERLINK using a prescaler.

POWERLINK is a standard protocol for Fast Ethernet with hard real-time characteristics. The POWERLINK Standardization Group (EPG) ensures openness and continuous advancement. www.ethernet-powerlink.org

The bus modules expanded to the left allow connection of up to 2 hub expansion modules in addition to the bus controller. Each expansion module is equipped with 2 RJ45 connections. This means that a basic device provides up to 6 hub connections.

- POWERLINK
- I/O configuration and firmware update via the fieldbus
- Integrated hub for efficient cabling
- Up to 2 slots for hub expansion modules
- 2x/4x/6x Fast Ethernet hub

Notice!

Using the bus controller together with the X20HB1881 and X20HB2881 fiber optic cable connectors.

- **X20BC8083: Hardware revision G0 up to and including I0**
- **X20cBC8083: All hardware revisions up to and including I0**

In rare cases, a firmware update or reconnection of the bus controller may make it so the connection to the connected X20HB modules can no longer be established.

This problem can be corrected by restarting (removing power to) the bus controller or reconnecting (hot plugging) the X20HB modules.

Combining the bus controller with other X20HB modules does not cause any problems.

9.19.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.19.3.2.1 Starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.19.3.3 Order data

| Model number | Short description | Figure |
|--|--|---|
| Expandable bus controllers | |  |
| X20BC8083 | X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, supports expansion with X20 hub modules, 2 RJ45, order bus base, power supply module and terminal block separately. | |
| X20cBC8083 | X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, supports X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately | |
| Required accessories | | |
| System modules for bus controllers | | |
| X20BB80 | X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/X20AC0SR1 included | |
| X20PS9400 | X20 power supply module, for bus controller and internal I/O power supply, X2X Link power supply | |
| X20PS9402 | X20 power supply module, for bus controller and internal I/O power supply, X2X Link power supply, supply not electrically isolated | |
| X20cBB80 | X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/X20AC0SR1 included | |
| X20cPS9400 | X20 power supply module, coated, for bus controller and internal I/O power supply, X2X Link power supply | |
| System modules for expandable bus controllers | | |
| X20BB81 | X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | |
| X20BB82 | X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with 2 expansion slots for 2 X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | |
| X20cBB81 | X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | |
| X20cBB82 | X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with two expansion slots for two X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | |
| Terminal blocks | | |
| X20TB12 | X20 terminal block, 12-pin, 24 VDC keyed | |
| Optional accessories | | |
| System modules for the X20 hub system | | |
| X20HB1881 | X20 hub expansion module, integrated 1-port hub, for multimode fiber optic cable | |
| X20HB1882 | X20 hub expansion module, integrated 1-port hub, for monomode fiber optic cables | |
| X20HB2880 | X20 hub expansion module, integrated 2-port hub, 2x RJ45 | |
| X20HB2881 | X20 hub expansion module, integrated 2-port hub, for fiber optic cable | |
| X20cHB1881 | X20 hub expansion module, coated, integrated 1-port hub, for fiber optic cable | |
| X20cHB2880 | X20 hub expansion module, coated, integrated 2-port hub, 2x RJ45 | |
| X20cHB2881 | X20 hub expansion module, coated, integrated 2-port hub, for fiber optic cable | |

Table 398: X20BC8083, X20cBC8083 - Technical data

- 1) See Automation Help under "Communication / POWERLINK / General information / Hardware - CN" for more information.
- 2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
- 3) Spacing is based on the width of the X20BB80 bus base. Up to 2 X20HB2880 hub expansion modules and 1 X20PS9400 or X20PS9402 power supply module are also always required for the bus controller.

9.19.3.5 Operating and connection elements

9.19.3.5.1 LED status indicators

| Figure | LED | Color | Status | Description | |
|---|-------------------|---------|--------------|--|---|
|  | S/E ¹⁾ | Green | Off | No power supply or mode NOT_ACTIVE. The controlled node (CN) is either not supplied with power, or it is in state NOT_ACTIVE. The CN waits in this state for about 5 seconds after a restart. Communication is not possible with the CN. If no POWERLINK communication is detected during these 5 seconds, the CN enters state BASIC_ETHERNET (flickering). If POWERLINK communication is detected before this time expires, however, the CN immediately enters state PRE_OPERATIONAL_1. | |
| | | | Flickering | Mode BASIC_ETHERNET. The CN has not detected any POWERLINK communication. In this state, it is possible to communicate directly with the CN (e.g. with UDP, IP, etc.) If communication POWERLINK is detected in this state, the CN switches to PRE_OPERATIONAL_1. | |
| | | | Single flash | Mode PRE_OPERATIONAL_1. When operating on a POWERLINK V1 manager, the CN switches directly to PRE_OPERATIONAL_2. When operated on a POWERLINK V2 manager, the CN waits until an SoC frame is received and then switches to the PRE_OPERATIONAL_2 state. | |
| | | | Double flash | Mode PRE_OPERATIONAL_2. The CN is normally configured by the manager in this state. It is then switched to state READY_TO_OPERATE by command (POWERLINK V2) or by setting the "data valid" flag in the output data (POWERLINK V1). | |
| | | | Triple flash | Mode READY_TO_OPERATE. In network POWERLINK V1, the CN switches automatically to OPERATIONAL as soon as input data is present. In a POWERLINK V2 network, the manager switches to the OPERATIONAL state by issuing a command. | |
| | | | On | Mode OPERATIONAL. The PDO mapping is active and cyclic data is evaluated. | |
| | | | Blinking | Mode STOPPED. Output data is not being output, and no input data is being provided. It is only possible to switch to or leave this state after the manager has given the appropriate command. | |
| | | | Red | On | The controlled node (CN) is in an error state (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: <ul style="list-style-type: none"> • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  <p>Note:</p> <ul style="list-style-type: none"> • Several red blinking signals are displayed immediately after the device is switched on. This is not an error, however. • The LED is lit red for CNs with configured physical node number 0 but that have not yet been assigned a node number via dynamic node allocation (DNA). |
| | | L/A IFx | Green | On | Link established to the remote station |
| | | | | | Blinking |

1) The Status/Error LED "S/E" is a green/red dual LED.

LED status indicators - Blink times

9.19.3.5.2 POWERLINK node number

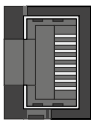

The node number for the POWERLINK node is set using the two number switches.

| Switch position | Description |
|-----------------|--|
| 0x00 | Only permitted when operating the POWERLINK node in DNA mode. |
| 0x01 - 0xEF | Node number of the POWERLINK node. Operation as a controlled node. |
| 0xF0 - 0xFF | Reserved, switch position not permitted. |

9.19.3.5.3 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see ["Cabling guidelines for X20 modules with an Ethernet cable"](#) on page 58.

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.19.3.5.4 Slot for hub expansion modules

Depending on the bus base, up to 2 hub expansion modules can be installed on the left side of the bus controller:

| Bus base | Slots for hub expansion modules |
|----------|---------------------------------|
| X20BB81 | 1 |
| X20BB82 | 2 |

Hub expansion module X20HB2880 can be connected to the bus controller and is equipped with 2 RJ45 connections, which means that up to 6 hub ports are available.

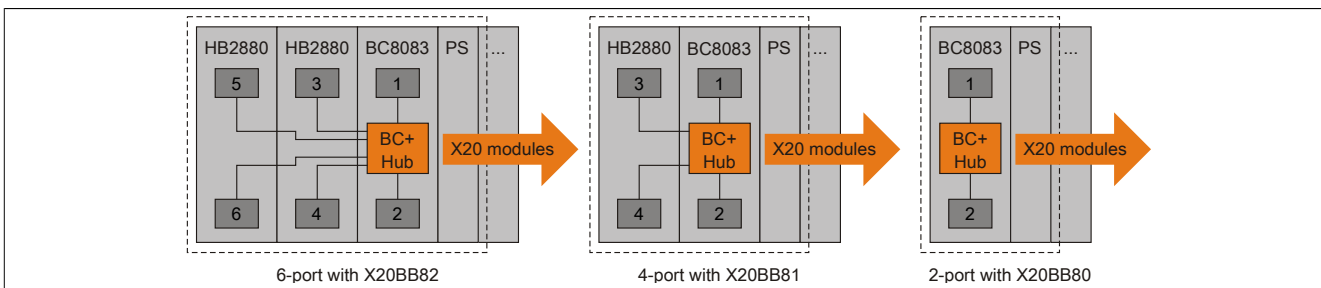

Figure 159: Numbering of hub ports

When using DNA, the desired hub port number must be specified under "Hub port on predecessor" in Automation Studio.

9.19.3.6 Dynamic node allocation (DNA)

Most POWERLINK bus controllers have the ability to dynamically assign node numbers. This has the following advantages:

- No setting of the node number switch
- Easier installation
- Reduced error sources

For information regarding configuration as well as an example, see Automation Help → Communication → POWERLINK → General information → Dynamic node allocation (DNA)

Information:

Interface IF1 must always be used as the input from the preceding node.

9.19.3.7 SG3

This module is not supported on SG3 target systems.

9.19.3.8 SG4

The module comes with preinstalled firmware. The firmware is also part of the Automation Runtime operating system for the PLC. With different versions, the Automation Runtime firmware is loaded onto the module.

The latest firmware is made available automatically when updating Automation Runtime.

9.19.4 X20(c)BC8084

Data sheet version: 2.39

9.19.4.1 General information

The bus controller makes it possible to connect X2X Link I/O nodes to POWERLINK. It is also possible to operate the X2X Link cycle synchronously 1:1 or synchronous to POWERLINK using a prescaler.

POWERLINK is a standard protocol for Fast Ethernet with hard real-time characteristics. The POWERLINK Standardization Group (EPSG) ensures openness and continuous advancement. www.ethernet-powerlink.org

Systems with redundant cabling can be implemented easily using POWERLINK. Unlike ring redundancy, cable redundancy does not require cable looping, which can sometimes be problematic. This allows the creation of all types of tree structures. When using a device with the link selector function, data is always transferred via the highest quality network lines. The link selector function is integrated in the bus controller.

- POWERLINK
- I/O configuration and firmware update via the fieldbus
- Integrated compact link selector function
- 2 active hub expansion modules can be connected to the bus controller
- Redundant supply possible

Notice!

Using the bus controller up to and including hardware revision G0 together with the X20HB1881 and X20HB2886 fiber optic cable connectors:

In rare cases, a firmware update or reconnection of the bus controller may make it so the connection to the connected X20HB modules can no longer be established.

This problem can be corrected by restarting (removing power to) the bus controller or reconnecting (hot plugging) the X20HB modules.

When using cable redundancy, the communication remains within the system if the redundant X20HB modules are reconnected individually and not at the same time!

Combining the bus controller with other X20HB modules does not cause any problems.

9.19.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.19.4.2.1 Starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C . During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.19.4.6 SG3

This module is not supported on SG3 target systems.

9.19.4.7 SG4

The module comes with preinstalled firmware. The firmware is also part of the Automation Runtime operating system for the PLC. With different versions, the Automation Runtime firmware is loaded onto the module.

The latest firmware is made available automatically when updating Automation Runtime.

9.19.4.8 POWERLINK cable redundancy system

It is often indispensable to have redundant network cabling, especially in systems that handle technical processes. The potential for danger, especially to the lines that run through the system, is disproportionately high in relation to the need to keep communication active in all operating situations. This risk is effectively reduced with double cabling that is routed separately.

The POWERLINK cable redundancy system is based on the principle of doubling the transfer routing as well as providing continual and simultaneous monitoring. That means data is simultaneously fed into two cable lines using a corresponding mechanism. The same mechanisms are used to receive these telegrams from the redundant network.

Information:

Details about the structure of a redundancy system can be found in the "Redundancy for control systems" user's manual. The user's manual is available in the Downloads section of the B&R website www.br-automation.com.

9.19.4.9 Redundant supply voltage

When operating the bus controller with two X20HB2885 hub modules, a redundant supply voltage for the system can be easily implemented using two X20 supply modules.

Hardware configuration for redundant supply voltage

Connection example for supply modules

X20PS9400

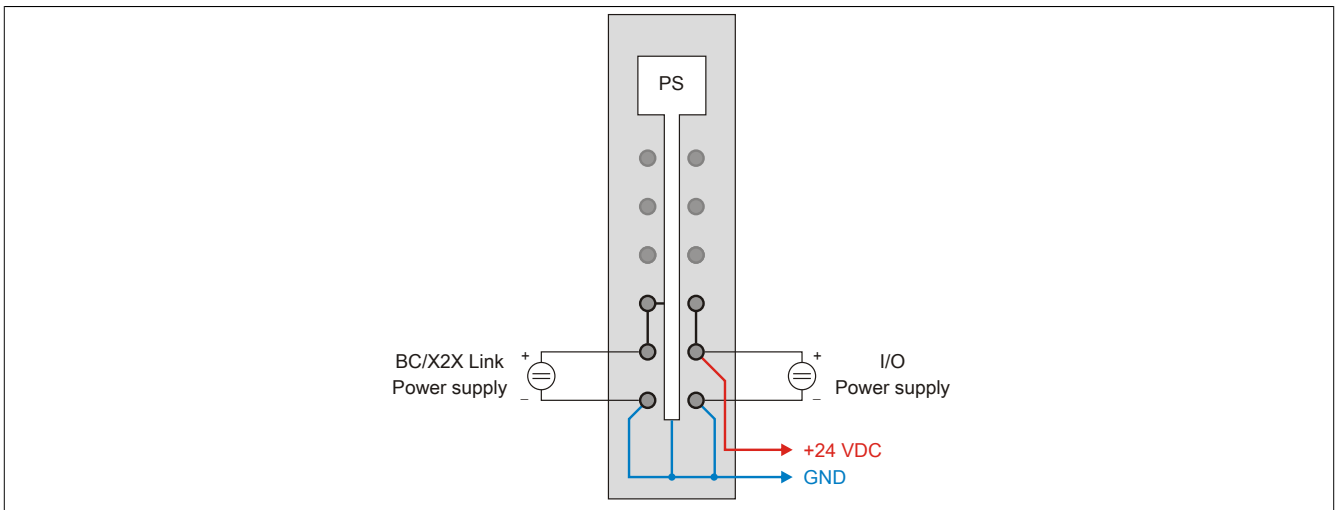

Figure 160: The X20PS9400 is connected as usual

X20PS3300

The supply module X20PS3300 is operated with a X20BM11 bus module. Only the BC/X2X Link supply is connected. A redundant I/O supply is not possible. By using the X20BM11 bus module, the I/O supply of the X20PS9400 supply module is connected to the I/O modules.

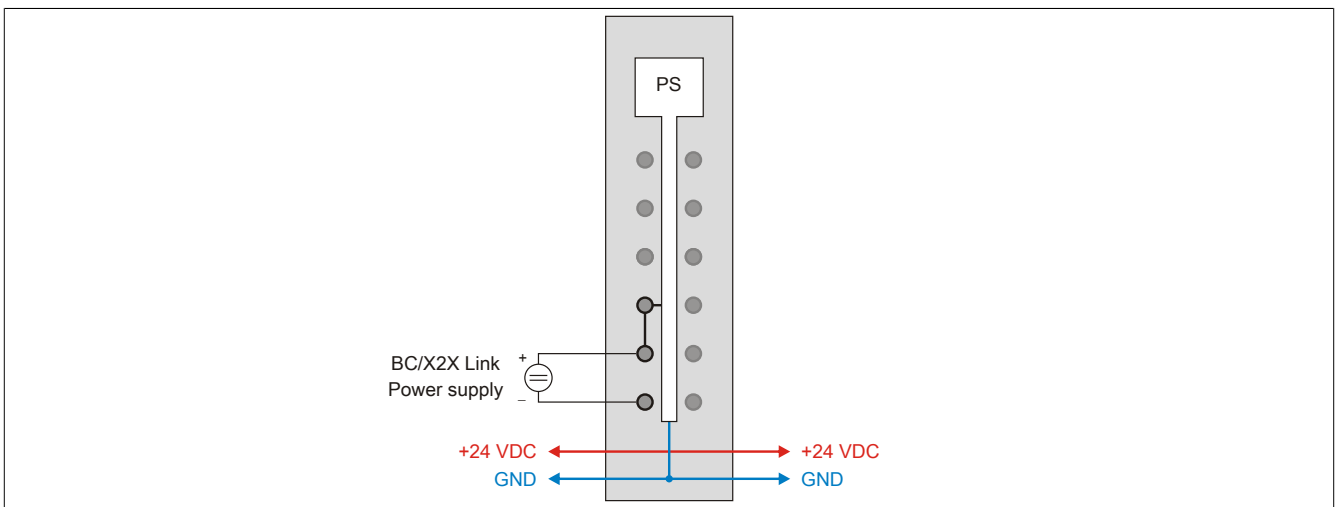

Figure 161: Only the BC/X2X Link supply is connected for the X20PS3300

9.20 Expandable bus controllers system modules

The expandable X20 bus controllers are made up of a bus controller fieldbus interface, a bus controller system module and an X20TB12 terminal block.

Expandable bus controller system modules include the base module and the supply module for providing power to the entire system.

9.20.1 Summary

| Model number | Short description | Page |
|--------------|--|------|
| X20BB81 | X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | 2234 |
| X20BB82 | X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with 2 expansion slots for 2 X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | 2237 |
| X20IF1091-1 | X20 interface module, for expandable bus controller, 1 X2X Link master interface, electrically isolated, order 1x TB704 terminal block separately | 2240 |
| X20cBB81 | X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | 2234 |
| X20cBB82 | X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with two expansion slots for two X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | 2237 |

9.20.2 X20(c)BB81

Data sheet version: 2.35

9.20.2.1 General information

The bus module has an expansion slot. The following modules are used on this module:

- Base module (BC, HB, etc.)
- Add-on module (IF, HB, etc.)
- Supply module

The left and right end plates are included in the delivery.

- Bus base with one expansion slot

Information:

The bus controller must be placed in the rightmost slot.

9.20.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.20.2.2.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

Table 406: X20IF1091-1 - Technical data

9.20.4.4 Usage with POWERLINK bus controllers

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.20.4.5 LED status indicators

| Figure | LED | Color | Status | Description |
|---|--------|--------|--------|--|
|  | STATUS | Green | On | Interface module active |
| | | Red | On | Bus controller booting |
| | X2X | Yellow | On | The module sends data via the X2X Link interface |

| | 3 | X2X _I | |
| | 4 | SHLD | Shield |

9.20.4.8 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.21 Fieldbus CPUs

Fieldbus CPUs are a variant of the Compact CPUs. Their modular structure allows them to be quickly and easily assembled according to the individual requirements of the application. All CPUs are based on embedded micro-processors and available in 2 performance classes.

Available interfaces

Communication takes place over an Ethernet interface and RS232. An optional CAN interface is also available. If needed, up to 2 slots are also available for modular interface expansion.

Maintenance-free CPU

The CPUs were designed without fans or batteries in order to make them as easy as possible to service. This makes them completely maintenance-free.

Compact design

The supply for the CPU, X2X Link network and I/O modules is part of the CPU. No additional power supply modules are required.

9.21.1 Summary

| Model number | Short description | Page |
|--------------|--|------|
| X20XC0201 | X20 fieldbus CPU, μ P 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus and interface module according to fieldbus CPU base, order power supply module, bus base and terminal block separately | 2245 |
| X20XC0202 | X20 fieldbus CPU, μ P 25, 750 kB SRAM, 3 MB FlashPROM, support of RS232, CAN bus and interface module according to fieldbus CPU base, order power supply module, bus base and terminal block separately | 2245 |
| X20XC0292 | X20 fieldbus CPU, μ P 25 750 kB SRAM, 3 MB FlashPROM, support of RS232, CAN bus and interface module, according to fieldbus CPU base, 1 Ethernet interface 100 Base-T, order bus base, power supply module and terminal block separately | 2245 |

9.21.2 X20XC02xx

Data sheet version: 2.23

9.21.2.1 General information

Fieldbus CPUs are variants of Compact CPUs. In addition to these features, fieldbus modules can be connected to the left side. These CPUs make applications possible in which data preprocessing must take place remotely on the I/O bus interface.

- Embedded μ P 16 / μ P 25 with additional I/O processor
- 100/750 kB User SRAM
- 1 MB / 3 MB User FlashPROM
- X20XC0292: Onboard Ethernet
- Up to 2 slots for fieldbus modules
- No battery
- Width
 - 1 fieldbus slot: 62.5 mm
 - 2 fieldbus slots: 87.5 mm

| X20BB3x | 62.5 ^{+0.2} mm | | |
| X20BB4x | 87.5 ^{+0.2} mm | | |

Table 408: X20XC0201, X20XC0202, X20XC0292 - Technical data

- 1) The real-time clock is buffered for approx. 1000 hours by a gold foil capacitor. The gold foil capacitor is completely charged after 18 continuous hours of operation.
- 2) This FRAM stores its contents ferroelectrically. Therefore, no backup battery is needed.
- 3) Not buffered.
- 4) For technical data, see the data sheet for the X20PS9500 power supply module.
- 5) For technical data, see the data sheet for the X20PS9502 power supply module.
- 6) Spacing is based on the width of the X20BB3x/4x fieldbus CPU base. The CPU always requires up to two fieldbus modules and one supply module X20PS9500 or X20PS9502.

9.21.2.4 LED status indicators

X20XC020x

| Figure | LED | Color | Status | Description |
|---|-----|--------|--------|---------------------|
|  | R/E | Green | On | Application running |
| | | Red | On | SERVICE mode |
| | | | Off | ¹⁾ |
| | RDY | Yellow | On | SERVICE mode |
| | | | Off | ¹⁾ |
| | | | | |

- 1) BOOT mode: R/E and RDY LEDs are off and the power supply LED is blinking

X20XC0292

| Figure | LED | Color | Status | Description |
|---|-----|--------|----------|--|
|  | R/E | Green | On | Application running |
| | | Red | On | SERVICE mode |
| | | | Off | ¹⁾ |
| | RDY | Yellow | On | SERVICE mode |
| | | | Off | ¹⁾ |
| | L/A | Green | On | A link to the peer station has been established. |
| | | | Blinking | A link to the peer station has been established. Indicates Ethernet activity is taking place on the bus. |

- 1) BOOT mode: R/E and RDY LEDs are off and the power supply LED is blinking

9.21.2.5 Operating and connection elements

X20XC0201 and X20XC0202

X20XC0292

9.21.2.6 Node number switches

The node number is set using the two hex switches. The switch setting can be evaluated by the application program at any time. The operating system only evaluates the switch position when the device is switched on.

| Switch position | Operating mode | Description |
|-----------------|----------------|---|
| 0x00 | BOOT | In this switch position, the operating system can be installed via the RS232 interface configured as the online interface. User Flash is deleted only after the update begins. |
| 0x01 - 0xFE | RUN | RUN mode, the application is running. |
| 0xFF | Diagnostics | Boots the CPU in Diagnostics mode. Program sections in User RAM and User FlashPROM are not initialized. Following diagnostics mode, the CPU always boots with a cold restart . |

X20XP0201 and X20XP0202

When used with the X20BB37 or X20BB47 bus module, the CPUs have access to a CAN bus interface. The INA2000 station number for CAN is set using the node number switches.

X20XP0292

This CPU is equipped with an onboard Ethernet interface. When used with the X20BB37 or X20BB47 bus module, it also has access to a CAN bus interface.

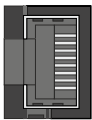

The number set using the two hex switches defines the INA2000 station number of both the CAN and the Ethernet interface.

9.21.2.7 Ethernet interface (IF2)

The X20XC0292 is equipped with an Ethernet interface. The connection is made using a 100 BASE-T twisted pair RJ45 socket.

Pinout

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

For information about wiring X20 modules with an Ethernet interface, see "[Cabling guidelines for X20 modules with an Ethernet cable](#)" on page 58.

Information:

The Ethernet interface (IF2) is not suited for POWERLINK.

Starting with operating system version 1.07, CPUs have a default IP address.

IP address: 192.168.0.1
 Subnet mask: 255.255.0.0

9.21.2.8 Slot for fieldbus modules

Up to two fieldbus modules can be connected to the left side of the Fieldbus CPUs depending on the CPU base:

| CPU base | Slots for fieldbus modules |
|------------------|----------------------------|
| X20BB32, X20BB37 | 1 |
| X20BB42, X20BB47 | 2 |

Table 409: X20 Fieldbus CPUs - Slots for fieldbus modules depending on CPU base

The X20 system can be connected to various bus and network systems by selecting the appropriate fieldbus modules. The following fieldbus modules can be operated with the CPUs:

| Module | Description |
|-------------|--|
| X20IF1020 | X20 interface module, 1 RS232, max. 115.2 kbit/s, electrically isolated |
| X20IF1030 | X20 interface module, 1 RS485/RS422, max. 115.2 kbit/s, electrically isolated |
| X20IF1041-1 | X20 interface module for DTM configuration, 1 CANOpen master interface, electrically isolated |
| X20IF1043-1 | X20 interface module for DTM configuration, 1 CANOpen slave interface, electrically isolated |
| X20IF1051-1 | X20 interface module for DTM configuration, 1 DeviceNet scanner interface, electrically isolated |
| X20IF1053-1 | X20 interface module for DTM configuration, 1 DeviceNet slave (adapter) interface, electrically isolated |
| X20IF1061 | X20 interface module, 1 Profibus DP master interface, max.12 Mbit/s, max. 3.5 KB input data and max. 3.5 KB output data, electrically isolated |
| X20IF1061-1 | X20 interface module for DTM configuration, 1 PROFIBUS DP V1 master interface, electrically isolated |
| X20IF1063 | X20 interface module, 1 Profibus DP slave interface, max.12 Mbit/s, electrically isolated |
| X20IF1063-1 | X20 interface module for DTM configuration, 1 PROFIBUS DP V1 slave interface, electrically isolated |
| X20IF1074 | X20 interface module for SGC, 1 CAN interface, max. 1 Mbit/s, electrically isolated,... |
| X20IF10A1-1 | X20 interface module for DTM configuration, 1 ASI master interface, electrically isolated |
| X20IF10D1-1 | X20 interface module for DTM configuration, 1 EtherNet/IP scanner interface, electrically isolated |
| X20IF10D3-1 | X20 interface module for DTM configuration, 1 EtherNet/IP slave interface, electrically isolated |
| X20IF10E1-1 | X20 interface module for DTM configuration, 1 PROFINET RT controller (master), electrically isolated |
| X20IF10E3-1 | X20 interface module for DTM configuration, 1 PROFINET RT device (slave), electrically isolated |
| X20IF10G3-1 | X20 interface module for DTM configuration, 1 EtherCAT slave interface, electrically isolated |
| X20IF10H3-1 | X20 interface module for DTM configuration, 1 Sercos III slave interface, electrically isolated |

Table 410: X20 fieldbus CPUs - Possible fieldbus modules

9.21.2.9 Programming the system flash memory

General information

CPUs are delivered with a runtime system. When delivered, the node number switch is set to switch position 0x00 (bootstrap loader mode).

A suitable switch position must be set (0x01 to 0xFE) in order to boot the PLC in RUN mode. Updating the runtime system is only possible in RUN mode.

Runtime system update

The runtime system can be updated via the programming environment. When updating the runtime system via an online connection, the following procedure must be carried out:

1. An online runtime system update is only possible if the processor is in RUN mode. For this to be true, the node number must be set to a value in the range 0x01 to 0xFE.
2. Switch on the power.
3. The runtime system update is performed via the existing online connection. The online connection can be established via the onboard serial RS232 interface, for example. If a CPU has an Ethernet interface, then it too can be used to perform the update.
4. Start B&R Automation Studio.
5. Start the update procedure by selecting **Online** from the **Project** menu. Select **Transfer Automation Runtime** from the pop-up menu. Now follow the instructions given by B&R Automation Studio.
6. A window opens up for setting the runtime system version. The runtime system version is already pre-selected by the project settings made by the user. The drop-down menu can be used to select one of the runtime system versions stored in the project. Clicking on the **Browse** button allows a runtime system version to be loaded from the hard drive or CD.

Clicking on **Next** opens a pop-up window that allows the user to select whether modules with target memory SYSTEM ROM should be transferred during the subsequent runtime system update. If not, these modules can also be transferred later during an application download.

Clicking on **Next** opens a dialog box where the user can set the CAN transfer rate, CAN ID and CAN node number (the CAN node number set here is only relevant if an interface module does not have a CAN node number switch). The CAN node number must be between decimal 01 and 99. Assigning a unique node number is especially important with online communication over a CAN network (INA2000 protocol).

7. The update procedure is started by clicking on **Next**. Update progress is shown in a message box.

Information:

User flash memory is deleted.

8. When the update procedure is complete, the online connection is reestablished automatically.
9. The PLC is now ready for use.

Updating the runtime system is possible not only via an online connection, but also via a CAN network, serial network (INA2000 protocol) or Ethernet network, depending on the system configuration.

9.22 Fieldbus CPUs system modules

The X20 system Fieldbus CPUs consist of the Fieldbus CPU, Fieldbus CPU system modules and the X20TB12 terminal block.

Fieldbus CPU system modules include the base module and the supply modules for providing power to the entire system.

9.22.1 Summary

| Model number | Short description | Page |
|--------------|---|------|
| X20BB32 | X20 Fieldbus CPU base, for Fieldbus CPU and Compact CPU power supply module, base for integrated RS232 interface, slot for X20 interface module, X20 connection, X20 end cover plates (left and right) X20AC0SL1/X20AC0SR1 included | 2253 |
| X20BB37 | X20 Fieldbus CPU base, for Fieldbus CPU and Compact CPU power supply module, base for integrated RS232 and CAN bus interface, slot for X20 interface module, X20 connection, X20 end cover plates (left and right) X20AC0SL1/X20AC0SR1 included | 2255 |
| X20BB42 | X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 interface, 2 slots for X20 interface modules, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | 2258 |
| X20BB47 | X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, 2 slots for X20 interface modules, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included | 2260 |
| X20IF1074 | X20 interface module, for SGC, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately | 2263 |

9.22.2 X20BB32

Data sheet version: 2.25

9.22.2.1 General information

The bus module is the base for all X20 Fieldbus CPUs.

The left and right end plates are included in the delivery.

- Base for all X20 Fieldbus CPUs
- RS232 connection

Information:

The Fieldbus CPU must be placed in the rightmost slot.

9.22.2.2 Order data

| Model number | Short description | Figure |

9.22.6 X20IF1074

Data sheet version: 2.23

9.22.6.1 General information

The module is an interface module for the X20 fieldbus CPU.

- CAN bus connection
- Integrated terminating resistor

Information:

This module does not support CAN RTR messages with extended CAN identifiers (29-bit) (memory/performance bottleneck).

Table 420: X20IF1074 - Technical data

9.22.6.4 LED status indicators

| Figure | LED | Color | Status | Description |
|---|--------|--------|--------|--|
|  | STATUS | Green | On | Interface module active |
| | | Red | On | CPU starting up |
| | TxD | Yellow | On | The module is sending data via the CAN bus interface |
| | TERM | Yellow | On | Terminating resistor integrated in the module switched on. |

9.22.6.5 Operating and connection elements

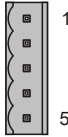

9.22.6.6 Node number switch

The node number for the interface is set with the two hex switches.

9.22.6.7 CAN bus interface

The interface is a 5-pin multipoint connector. Terminal block 0TB2105 must be ordered separately.

| Interface | | Pinout | |
|--|----------|------------------|------------|
|  5-pin male multipoint connector | Terminal | Function | |
| | 1 | CAN _⊥ | CAN ground |
| | 2 | CAN _L | CAN low |
| | 3 | SHLD | Shield |
| | 4 | CAN _H | CAN high |
| 5 | NC | | |

9.22.6.8 Terminating resistor

A terminating resistor is integrated in the interface module. It can be switched on or off with a switch on the bottom of the housing. A switched-on terminating resistor is indicated by LED "TERM".

9.22.6.9 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23 X20 interface module communication

The interface modules are added to the X20 CPU as an application-specific interface expansion.

9.23.1 Summary

| Model number | Short description | Page |
|--------------|---|------|
| X20IF1020 | X20 interface module, 1 RS232 interface, max. 115.2 kbit/s, electrically isolated | 2268 |
| X20IF1030 | X20 interface module, 1 RS422/485 interface, max. 115.2 kbit/s, electrically isolated | 2271 |
| X20IF1041-1 | X20 interface module, for DTM configuration, 1 CANopen master interface, electrically isolated, order 1x TB2105 terminal block separately | 2274 |
| X20IF1043-1 | X20 interface module, for DTM configuration, 1 CANopen slave interface, electrically isolated, order 1x TB2105 terminal block separately | 2288 |
| X20IF1051-1 | X20 interface module, for DTM configuration, 1 DeviceNet scanner (master) interface, electrically isolated, order 1x terminal block TB2105 separately! | 2302 |
| X20IF1053-1 | X20 interface module, for DTM configuration, 1 DeviceNet adapter (slave) interface, electrically isolated, order 1x terminal block TB2105 separately! | 2315 |
| X20IF1061-1 | X20 interface module for DTM configuration, 1 PROFIBUS DP V0/V1 master interface, electrically isolated | 2328 |
| X20IF1063 | X20 interface module, 1 PROFIBUS DP V0 slave interface, max. 12 Mbit/s, electrically isolated | 2339 |
| X20IF1063-1 | X20 interface module, for DTM configuration, 1 PROFIBUS DP V1 slave interface, electrically isolated | 2342 |
| X20IF1072 | X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately | 2353 |
| X20IF1082 | X20 interface module, 1 POWERLINK interface, managing or controlled node, integrated 2-port hub, ring redundancy function | 2357 |
| X20IF1082-2 | X20 interface module, 1 POWERLINK interface, managing or controlled node, integrated 2-port hub, ring redundancy function PRC function | 2363 |
| X20IF1086-2 | X20 interface module, 1 POWERLINK interface, managing or controlled node, PRC function, 1 fiber optic connection | 2369 |
| X20IF1091 | X20 interface module, 1 X2X Link master interface, electrically isolated, order 1x TB704 terminal block separately | 2375 |
| X20IF10A1-1 | X20 interface module, for DTM configuration, 1 ASi master interface, electrically isolated, order 1x terminal block TB704 separately! | 2378 |
| X20IF10D1-1 | X20 interface module, for DTM configuration, 1 EtherNet/IP scanner (master) interface, electrically isolated | 2392 |
| X20IF10D3-1 | X20 interface module, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated | 2402 |
| X20IF10E1-1 | X20 interface module, for DTM configuration, 1 PROFINET IO controller (master) interface, electrically isolated | 2413 |
| X20IF10E3-1 | X20 interface module, for DTM configuration, 1 PROFINET IO device (slave) interface module, electrically isolated | 2424 |
| X20IF10G3-1 | X20 interface module for DTM configuration, 1 EtherCAT slave interface, electrically isolated | 2434 |
| X20IF10X0 | X20 interface module, 1 redundancy link interface 1000BASE-SX, CPU-CPU data synchronization module for controller redundancy | 2447 |
| X20IF2181-2 | X20 interface module, 1x link selector for POWERLINK cable redundancy, POWERLINK functions: - Managing node - Controlled node for iCN operation - Redundant managing node for controller redundancy - Ring redundancy - 2x hub - Multi ASend - PRC function 2x RJ45 | 2452 |
| X20IF2772 | X20 interface module, 2 CAN bus interfaces, max. 1 Mbit/s, electrically isolated, order 2x TB2105 terminal block separately | 2458 |
| X20IF2792 | X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, 1 X2X Link master interface, electrically isolated, order 1x terminal block TB2105 and 1x terminal block TB704 separately! | 2462 |
| X20clF1030 | X20 interface module, coated, 1 RS422/485 interface, max. 115.2 kbit/s, electrically isolated | 2271 |
| X20clF1041-1 | X20 interface module, coated, for DTM configuration, 1 CANopen master interface, electrically isolated, order 1x TB2105 terminal block separately | 2274 |
| X20clF1061-1 | X20 interface module coated, for DTM configuration, 1 PROFIBUS DP V0/V1 master interface, electrically isolated | 2328 |
| X20clF1063-1 | X20 interface module, coated, for DTM configuration, 1 PROFIBUS DP V1 slave interface, electrically isolated | 2342 |
| X20clF1072 | X20 interface module, coated, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately | 2353 |
| X20clF1082-2 | X20 interface module, coated, 1 POWERLINK interface, managing or controlled node, integrated 2-port hub, ring redundancy function PRC function | 2363 |
| X20clF10D1-1 | X20 interface module, coated, for DTM configuration, 1 EtherNet/IP scanner (master) interface, electrically isolated | 2392 |
| X20clF10D3-1 | X20 interface module, coated, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated | 2402 |
| X20clF10E3-1 | X20 interface module, coated, for DTM configuration, 1 PROFINET IO device (slave) interface module, electrically isolated | 2424 |
| X20clF10X0 | X20 interface module, coated, 1 redundancy link interface 1000 Base-FX, CPU-CPU data synchronization for controller redundancy | 2447 |
| X20clF2181-2 | X20 interface module, coated, 1x link selector for POWERLINK cable redundancy, POWERLINK functions: - Managing node - Controlled node for iCN operation - Redundant managing node for controller redundancy - Ring redundancy - 2x hub - Multi ASend - PRC function 2x RJ45 | 2452 |

9.23.2 X20IF1020

Data sheet version: 2.23

9.23.2.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an RS232 interface.

- The RS232 interface can be configured as an online interface

9.23.2.2 Order data

| Model number | Short description | Figure |

9.23.2.7 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.3 X20(c)IF1030

Data sheet version: 2.34

9.23.3.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an RS485/RS422 interface.

- RS485/RS422 connection

9.23.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

1) RS422 send data is TRISTATE-capable.

9.23.3.8 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.4 X20(c)IF1041-1

Data sheet version: 2.03

9.23.4.1 General information

The interface module is equipped with a CANopen interface. This allows third-party components to be integrated in the B&R system and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

- CANopen master
- Integrated terminating resistor

9.23.4.1.1 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.4.2 Order data

9.23.4.4 Operating and connection elements

9.23.4.4.1 LED status indicators

| Figure | LED | Color | Status | Description |
|--------|-----------|--|---|--|
| | READY/RUN | Green/red | Off | No power to module |
| | | Green | On | PCI bus communication in progress |
| | | Red | Blinking | Error when booting |
| | | On | On | Communication on the PCI bus has not yet been started |
| | ERR/RUN | Green/red | Off | Module executes a reset |
| | | Green on Red blinking with double pulse | On | CANopen communication disrupted. This may be due to one of the following reasons: <ul style="list-style-type: none"> The CAN bus cable is broken or the CAN bus controller is in "Bus off" mode The module is in PREOPERATIONAL mode At least one configured CANopen slave is not functioning |
| | | Green on Red blinking | On | Communication was stopped (the module is in STOPPED mode) |
| | | Green | Blinking | Communication is being started (module is being initialized) |
| | | On | On | Communication is ready |
| | TxD | Yellow | Flickering or on | Module sending data via the CANopen interface |
| TERM | Yellow | On | Terminating resistor integrated in the module switched on | |

9.23.4.4.2 CAN bus interface

The interface is a 5-pin multipoint connector. Terminal block 0TB2105 must be ordered separately.

| Interface | Pinout | | |
|--|----------|------------------|------------|
| | Terminal | Function | |
| <p>5-pin male multipoint connector</p> | 1 | CAN _⊥ | CAN ground |
| | 2 | CAN _L | CAN low |
| | 3 | SHLD | Shield |
| | 4 | CAN _H | CAN high |
| | 5 | NC | |

9.23.4.4.3 Terminating resistor

A terminating resistor is integrated in the interface module. It can be switched on or off with a switch on the bottom of the housing. A switched-on terminating resistor is indicated by LED "TERM".

9.23.4.5 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.4.5.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.4.5.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.4.6 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.4.7 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.4.8 The CANopen interface

9.23.4.8.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

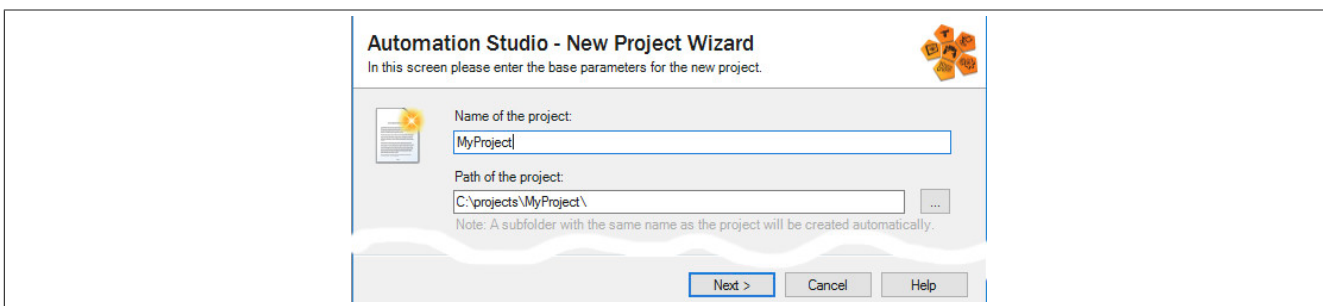

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.4.8.1.1 Creating an Automation Studio project

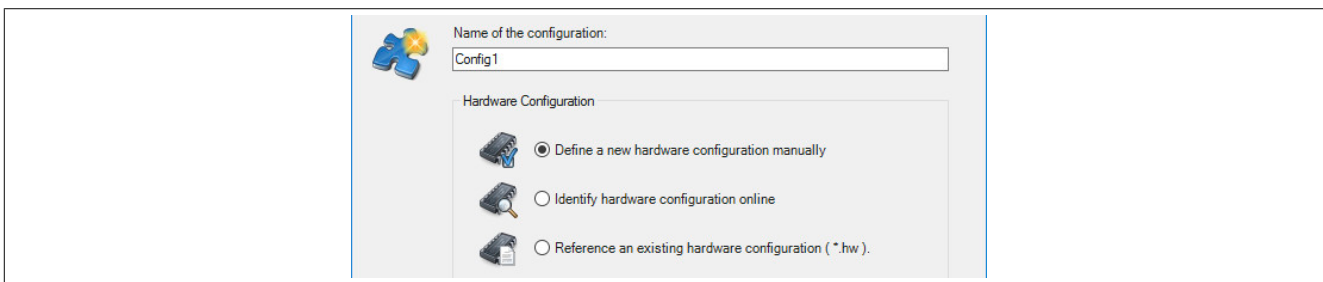

- Create a new Automation Studio project by selecting "New project".

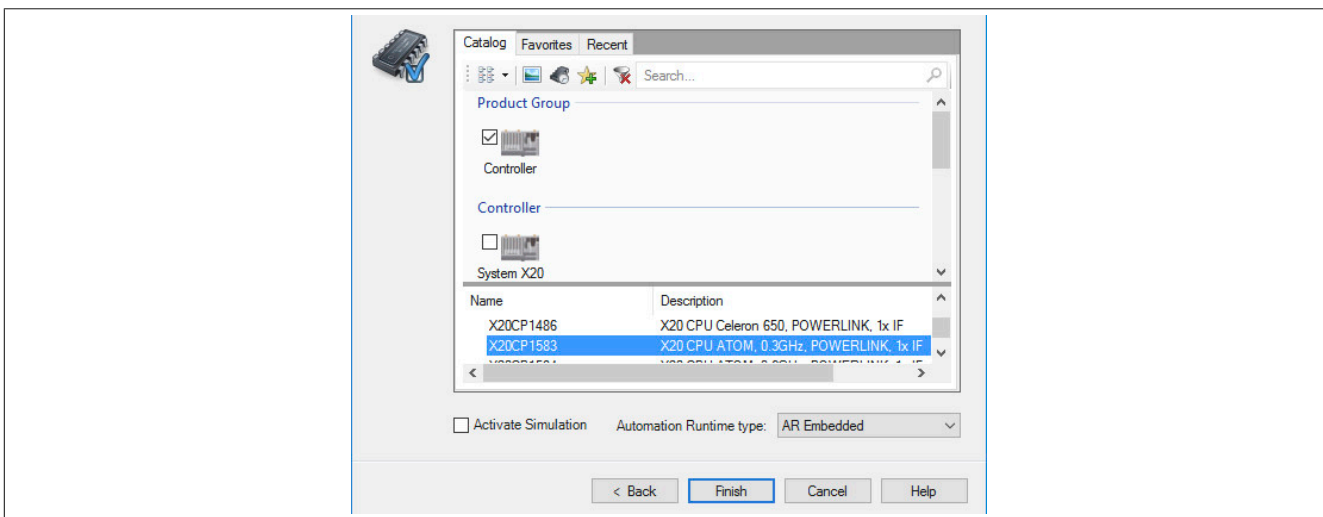

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

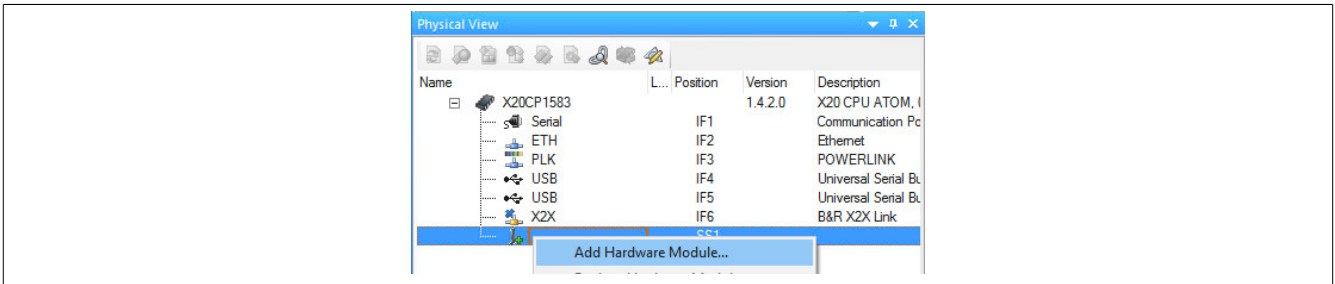

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

9.23.4.8.1.2 Adding and configuring the interface module

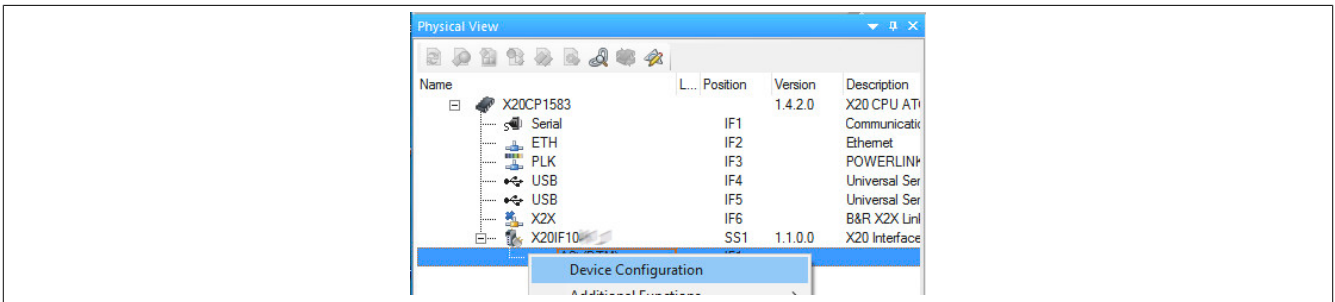

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

Master settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

- Module alignment

The addressing mode is defined by the process image here. The addresses (offsets) of the process data are always interpreted as byte addresses.

| Addressing mode | Explanation |
|-------------------|---|
| Byte boundaries | The module address can start on any offset. |
| 2 byte boundaries | The module address can only start on even byte offsets. |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|-----------------------------|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values | 20 to 65535 ms |
| | Default value: 1000 ms | |

Information:

The watchdog time is reset automatically by Automation Runtime.

- Process data handshake

This parameter configures the handshake for the data exchange between application and device. Only "Buffered, host-controlled" is supported here.

- Process image storage format

This is used to define how data is stored in the process image (I/O mapping). The storage format is only applied to data type "Word". This change has no effect on other data types.

| Storage format | Explanation |
|----------------|---|
| Big-endian | MSB/LSB = Higher/Lower byte (Motorola format) |
| Little-endian | MSB/LSB = Higher/Lower byte (Intel format) |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

- Advanced

This parameter is not supported.

- Device status offset

Here, the status offset can be set to be calculated automatically or using a predefined value.

| Status offset | Explanation |
|-----------------------|---|
| Automatic calculation | The device status always directly follows the input bytes. If input data is added in the configuration, the start address of the device status is moved back in the dual-ported memory. |
| Static | <p>Here, the distance (free buffer) between the last input byte and the start of the device status can be set. This way, the start address of the device status never changes in the dual-ported memory. If additional input data is added, the distance (free buffer) is reduced. If the free buffer does not have enough space available for the data added to it, the start address of the device status in the dual-ported memory must be shifted.</p> <p>If the offset is too small, an error is output. To correct the error, the free buffer must be increased to a sufficient size.</p>  |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

Bus parameters

- Device description

The symbolic name of the device can be changed here. However, this is only used by the configuration dialog boxes and not by Automation Studio.

- Node settings

The NodeID, baud rate and behavior at startup and in the event of error can be configured here.

| Parameter | Explanation | Values |
|----------------------------------|---|-----------------------|
| Node ID | The node ID is used in CANopen for addressing and each ID is only permitted to occur once in a network. | 1 to 127 |
| Baud rate | Configures the data transfer rate | 10 kbit/s to 1 Mbit/s |
| Stop in case of monitoring error | <p>How the master behaves in the event of a monitoring error is set here. In each case, the corresponding error code is output.</p> <ul style="list-style-type: none"> Enabled: The master switches to mode "Stop" and communication with all other slaves is aborted. Not enabled: The master remains in mode "Operational" and communication with the other slaves is maintained. | |
| Send "Global start node" | <p>If enabled, the master transmits a "Global start node" after the startup of all configured slaves. This synchronizes and starts all slaves.</p> <p>If a slave should not be started, both this parameter and "Send the start node command" must be disabled under "Node bootup" on page 2284. If only one of the two parameters is disabled, the slave is started.</p> | |

- SYNC master settings

The COB ID can be changed here. Each communication object in the network has a unique communication object identifier (COB ID).

In addition, the cyclic period of the SYNC message can be set or switched off (cycle period = 0).

| Sync object | Explanation | Values |
|--------------|---|--|
| COB ID | COB ID of the SYNC message Default value: 128 | 0 to 128 1664 to 1759 1761 to 1792 |
| Cycle period | Period of the SYNC message. The value 0 disables the transmission of messages. Default value: 100 | 0 to 65535 |

- 29-bit COB ID

This parameter is not supported.

Process data

This table lists the process data of the individual slaves.

| Parameter | Explanation |
|-----------|---|
| Type | Device designation specified by the hardware. Further description of modules configured on the device or the input or output signals. |
| Tag | The name of the input and output data can be changed in column "Day". |
| SCADA | This parameter is not supported. |

Address table

This table provides information about the addresses of the input and output data (in decimal or hexadecimal notation).

"Display mode" allows toggling between decimal and hexadecimal display.

| Column | Explanation |
|----------|---|
| Node ID | Node ID of the slave |
| Device | Device name of the slave |
| Name | Name of the slave |
| Obj.Idx | Object index |
| Obj.Name | Object name |
| COB ID | COB ID of the CAN message |
| Type | Data type for the input and output data |
| Length | Length of the input and output data |
| Address | Offset for the input and output data |

The address table can also be exported as a CSV file.

Node ID table

All slaves are listed in this table.

| Parameter | Explanation |
|-----------|--|
| Activate | This allows the slaves to be enabled or disabled. If a slave is disabled, the master reserves memory in the process data image for the slave, but no data is exchanged. If a slave is enabled, the process memory is reserved and data is exchanged. |
| Node ID | A node ID can be assigned to the slave here. |
| Device | Device name of the slave |
| Name | Name of the slave |
| Vendor | Device manufacturers |

SDO table

This table lists all objects that are transferred during the startup phase. The object information cannot be changed.

"Display mode" allows toggling between decimal and hexadecimal display.

| Column | Explanation |
|-----------|--------------------------|
| Node ID | Node ID of the slave |
| Device | Device name of the slave |
| Name | Name of the slave |
| Obj.Idx | Object index |
| Sub.Idx | Subindex |
| Parameter | Parameter name |
| Value | Value of the parameter |

CAN ID table

The CAN IDs used are listed in this table. If "Auto alloc = Enabled", the CAN IDs are assigned automatically. "Display mode" allows toggling between decimal and hexadecimal display.

| Column | Explanation | Values |
|--------------|---|---|
| Node ID | Station address of the device in the network | 1 to 127 |
| Device | Device name of the slave | |
| Name | Name of the slave | Any |
| Message type | Message type | <ul style="list-style-type: none"> • NODE GUARDING • EMCY • RXPDO[x] • TXPDO[x] • SYNC |
| CAN ID | COB ID | 0 to 2047 |
| Auto alloc | Enables/Disables automatic allocation To change a CAN ID, "Auto alloc" must be disabled. | |

| Message Type | CAN-ID | Auto Alloc |
|--------------|---|-------------------------------------|
| SYNC | 128 | <input type="checkbox"/> |
| EMCY | 130 | <input checked="" type="checkbox"/> |
| RxPDO_01 | 514 | <input checked="" type="checkbox"/> |
| RxPDO_02 | 770 | <input checked="" type="checkbox"/> |
| RxPDO_03 | 1026 | <input checked="" type="checkbox"/> |
| RxPDO_04 | 1282 | <input checked="" type="checkbox"/> |
| TxPDO_01 | <input style="border: 1px solid red;" type="text" value="386"/> | <input type="checkbox"/> |
| TxPDO_02 | 642 | <input checked="" type="checkbox"/> |
| TxPDO_03 | 898 | <input checked="" type="checkbox"/> |
| TxPDO_04 | 1154 | <input checked="" type="checkbox"/> |
| TxPDO_05 | 1791 | <input checked="" type="checkbox"/> |

Node bootup

The startup phase can be adjusted here. By disabling boot phases, these are not executed, e.g. to be able to transfer another configuration at a later time.

| Phase/Status | Parameter | Description |
|--|--|---|
| 1 - Node reset | Send the reset node command | If enabled, the master first transmits the CANopen-specific node reset command. |
| 2 - Check node, profile and type | Compare the configured profile and type object 1000H with real value | If enabled, the master compares the contents of object 0x1000 on the module with the set data. If the values do not match, the node is not accessed. The configuration is not transferred and a configuration error is reported. This option must be enabled if a node object is not defined in the EDS file. In this case, under "Profiles and type", the values for the profile and the device type of the node must be entered according to the specifications of the device manufacturer. "EDS default" resets the values for the profile and the device type of the node to the original values from the EDS file and disables the comparison. |
| 3 - Configuration, guarding protocol | Configure the guard time and lifetime factor | If enabled, the master writes the two objects 0x100C (guard time) and 0x100D (lifetime factor) into the corresponding node objects during startup. If not enabled, the last configured values are obtained from the slave. If the configuration on the slave has been deleted, these values are 0. |
| 4 - Configuration SYNC COB ID | Configure the COB ID for the synchronization message | If enabled, the master transfers the configuration of the SYNC COB ID set in Automation Studio under "SYNC master settings" on page 2281 to the slave (object 0x1005). However, if the set cycle period is 0, no SYNC messages are sent. If not enabled, the last configured value is obtained from the slave. If the configuration on the slave has been deleted, the default value is 0x80. |
| 5 - Configuration EMCY COB ID | Configure the COB ID for the emergency message | If enabled, the master transfers the fixed EMCY COB ID to the slave (object 0x1014). If not enabled, the last configured value is obtained from the slave. If the configuration on the slave has been deleted, the default value is 0x80 + NodeID. |
| 6 - Configuration, download of objects | Download the object configuration to the node | If enabled, the master transfers all relevant configuration objects to the node, e.g. information about the PDO mapping, the COB IDs of the transmit and receive PDOs and all configured objects from the node configuration. If not enabled, the slave receives no configuration from the master. Phases 3, 4 and 5 are also not executed. If the slave supports automatic configuration, only the first 4 PDOs are active. COB IDs are defined and obtained from the slave. |
| 7 - Start node | Send the start node command | If enabled, the master sends the CANopen-specific start node command at the end of the bootup procedure in order to achieve the operating state. |
| 8 - Initiate PDO data | Remote request all TxPDOs and send current RxPDOs once after bootup | If enabled, the master reads and writes the configured PDOs after startup. This transmits all current data from the process output data memory to the nodes in addition to reading all current data from the nodes and then storing it in the process input data area of the master. |

Information:

Parameters "Node boot up → Start node" and "Bus parameters → Send 'global start node'" must be considered together.

Example

If all boot phases have been disabled, but "Send 'Global start node'" is active, the slave is still started. In this case, communication is started without the configuration being applied.

Monitoring

Device monitoring can be configured here. The following types of monitoring are possible:

- The master monitors the individual nodes.
- A node monitors the master.
- One node monitors another node.

The node to be monitored can be selected in column "Active" of the table. For each node, the node guarding protocol or heartbeat protocol can be selected.

- Selected node

Contains all configured nodes.

- Node guarding protocol

The master transmits a cyclic poll request to the node to check whether the node still exists on the bus. The node transmits its current status back to the master as response. The node can use the poll request from the master in order to monitor the master.

| Parameter | Explanation |
|-----------------|---|
| Guarding time | Monitoring the slave from the point of view of the master If communication is running, the master queries the node at the set time interval to check whether the node is still present in the network. If the guarding time has the value 0, the monitoring is disabled on both the master and slave. |
| Lifetime factor | Using the slave to monitor the master. If the communication is running, the node monitors the master in the calculated time interval " <i>Guarding time * Lifetime factor</i> " to check whether the node is still present in the network. If the lifetime factor has the value 0, monitoring is disabled on the slave. |

Information:

In order to use the node guarding protocol, the node must support this protocol.

- Heartbeat protocol

A "heartbeat producer" transmits cyclic heartbeat requests. One or multiple "heartbeat consumers" can receive the request.

| Parameter | Explanation |
|---------------|--|
| Producer time | Time interval at which heartbeat requests are transmitted. |

Information:

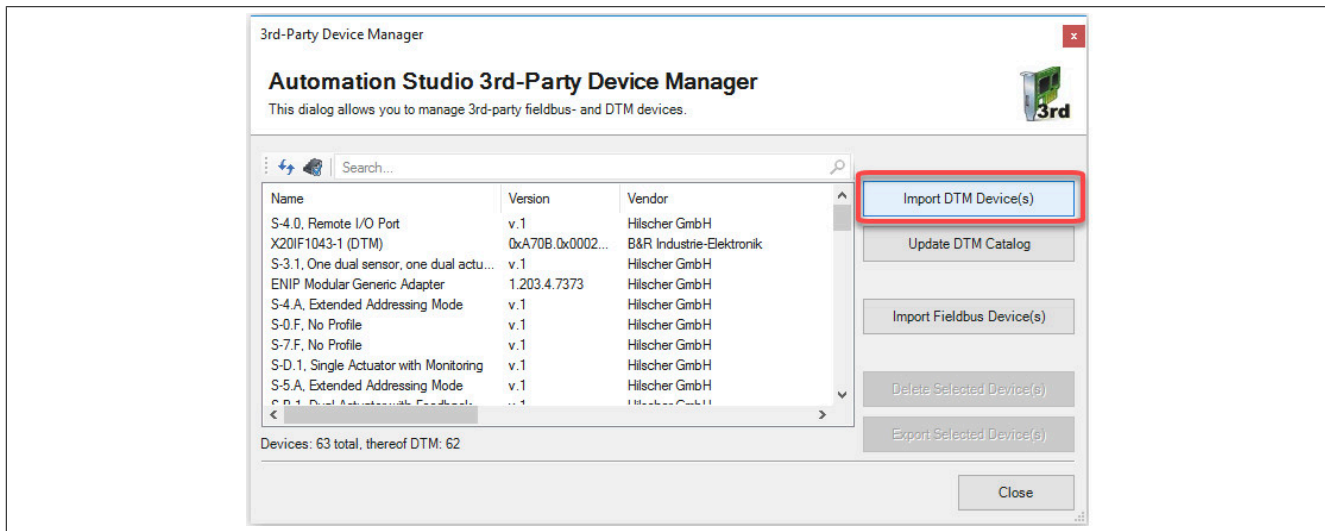

To use the heartbeat protocol, the node must support the heartbeat protocol.

9.23.4.8.2 Adding the EDS file in Automation Studio

A device description file (EDS, DCF file) is required to inform the CANopen master which slaves were connected and how they were configured.

To add and use a device description file in Automation Studio, perform the following steps:

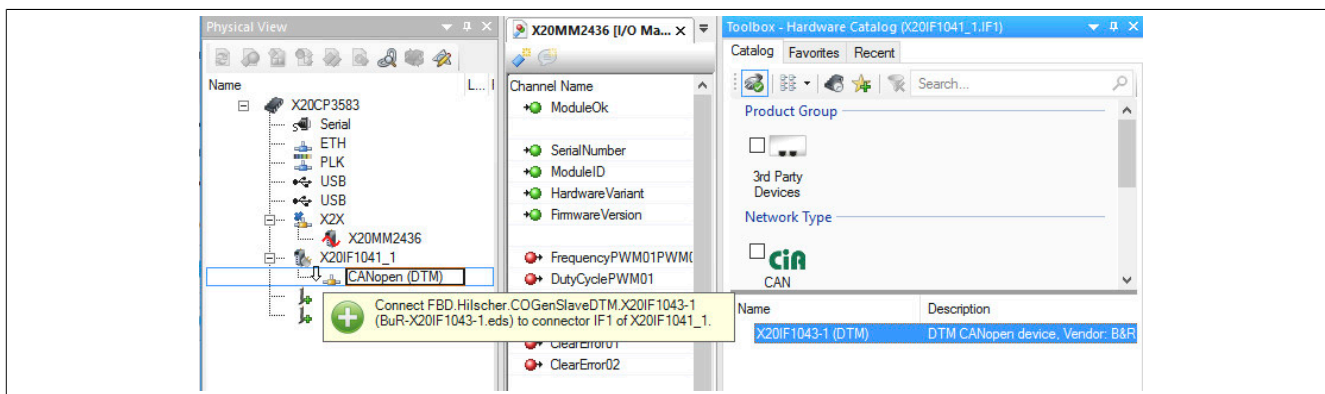

- The device description file (EDS, DCF) must be provided by the manufacturer of the CANopen slave.
- Open the dialog box in Automation Studio under "Tools - Manage 3rd-party devices" and select "Import DTM Device(s)".

- Select the EDS file to be imported and confirm with OK. The EDS file is imported into Automation Studio.

- Click on "CANopen (DTM)" on the CANopen master X20IF1041-1, drag the EDS file from the Hardware Catalog and attach it to the CANopen master.

- Right-click on the device description file and select "Device configuration" to open the configuration environment for the EDS file.

9.23.5 X20IF1043-1

Data sheet version: 2.03

9.23.5.1 General information

The interface module is equipped with a CANopen (slave) interface. This allows the B&R system (I/O modules, POWERLINK, etc.) to be connected to systems from other manufacturers and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

- CANopen slave
- Integrated terminating resistor

9.23.5.2 Order data

| Model number | Short description | Figure |
|--------------|--|--|
| | X20 interface module communication |  |

Table 428: X20IF1043-1 - Technical data

9.23.5.4 Operating and connection elements

9.23.5.4.1 LED status indicators

| Figure | LED | Color | Status | Description |
|--------|-----------|----------------------------------|---|---|
| | READY/RUN | Green/red | Off | No power to module |
| | | Green | On | PCI bus communication in progress |
| | | Red | Blinking | Error when booting |
| | | On | Communication on the PCI bus has not yet been started | |
| | ERR/RUN | Green/red | Off | Module executes a reset |
| | | Green blinking with double pulse | Red blinking with double pulse | CANopen communication disrupted. This may be due to one of the following reasons: <ul style="list-style-type: none"> The CAN bus cable is broken or the CAN bus controller is in "Bus off" mode The module is in PREOPERATIONAL mode CANopen communication was stopped (the module is in STOPPED mode) |
| | | Green blinking | Red blinking with double pulse | CANopen communication was stopped by the master |
| | | Green | Blinking | Communication is being started (module is being initialized) |
| | TxD | Yellow | Flickering or on | Module sending data via the CANopen interface |
| | TERM | Yellow | On | Terminating resistor integrated in the module switched on |

9.23.5.4.2 CAN bus interface

The interface is a 5-pin multipoint connector. Terminal block 0TB2105 must be ordered separately.

| Interface | Pinout | | |
|--|----------|------------------|------------|
| | Terminal | Function | |
| <p>5-pin male multipoint connector</p> | 1 | CAN _⊥ | CAN ground |
| | 2 | CAN _L | CAN low |
| | 3 | SHLD | Shield |
| | 4 | CAN _H | CAN high |
| | 5 | NC | |

9.23.5.4.3 Terminating resistor

A terminating resistor is integrated in the interface module. It can be switched on or off with a switch on the bottom of the housing. A switched-on terminating resistor is indicated by LED "TERM".

9.23.5.5 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.5.5.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.5.5.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.5.6 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.5.7 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.5.8 The CANopen interface

Information:

The settings on the slave must match the settings of the corresponding device description file; otherwise, no connection can be established.

9.23.5.8.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

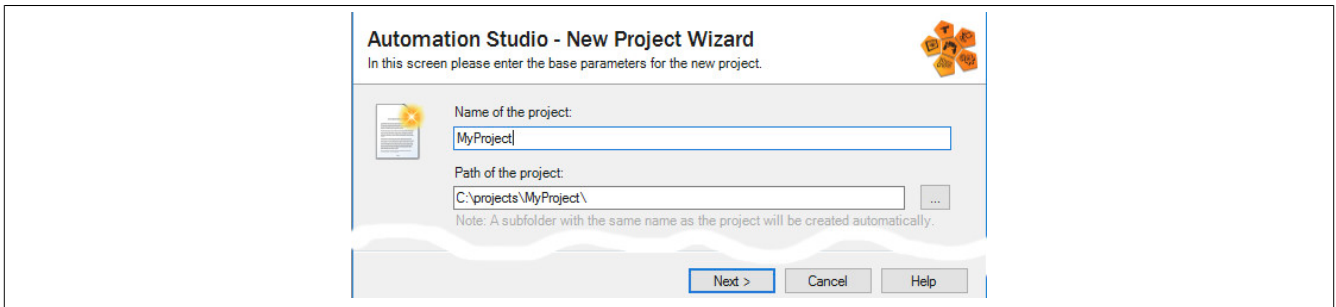

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.5.8.1.1 Creating an Automation Studio project

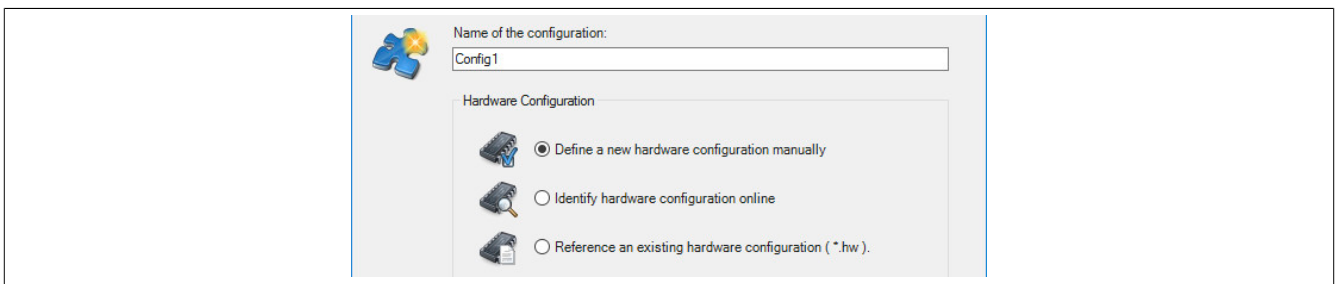

- Create a new Automation Studio project by selecting "New project".

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

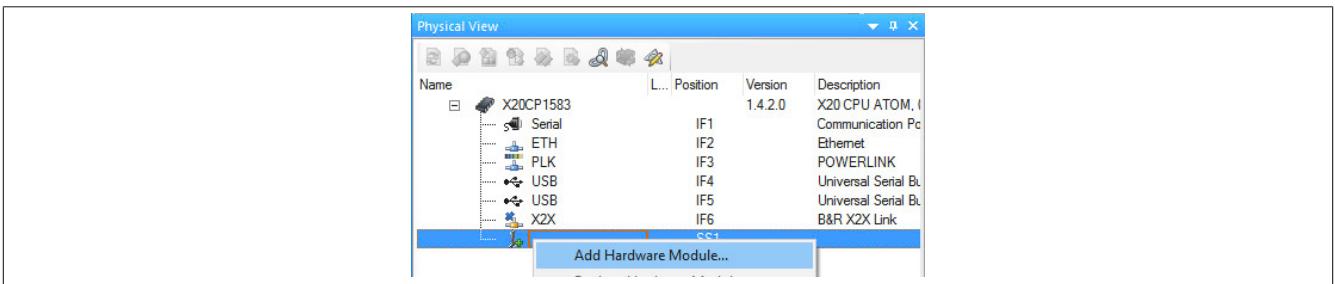

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

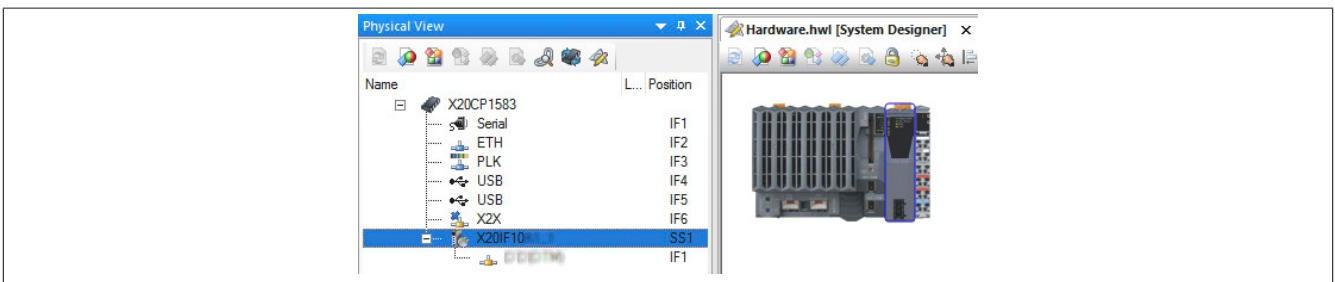

9.23.5.8.1.2 Adding and configuring the interface module

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

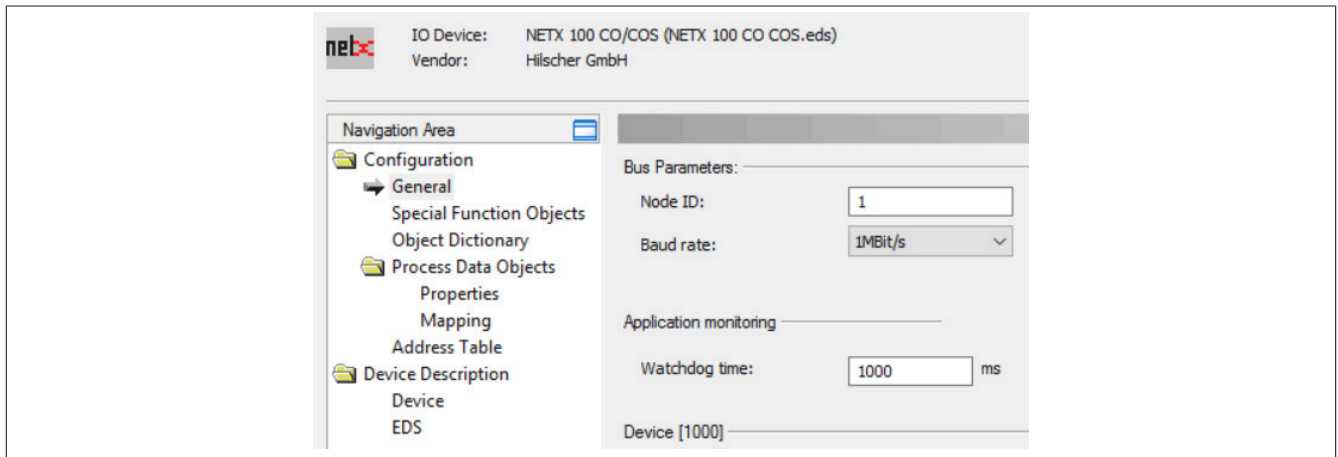

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

General

- Bus parameters

The NodeID and baud rate can be configured here.

These values from the EDS description file on the master can only be read.

| Parameter | Explanation | Values |
|-----------------------|---|-----------------------|
| Node ID | The node ID is used in CANopen for addressing and each ID is only permitted to occur once in a network. The same node ID must be set in the EDS description file on the master and slave. | 1 to 127 |
| Baud rate | Sets the transfer rate | 10 kbit/s to 1 Mbit/s |
| Enable address switch | This parameter is not supported. | |

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|-----------------------------|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values | 20 to 65535 ms |
| | Default value: 1000 ms | |

Information:

The watchdog time is reset automatically by Automation Runtime.

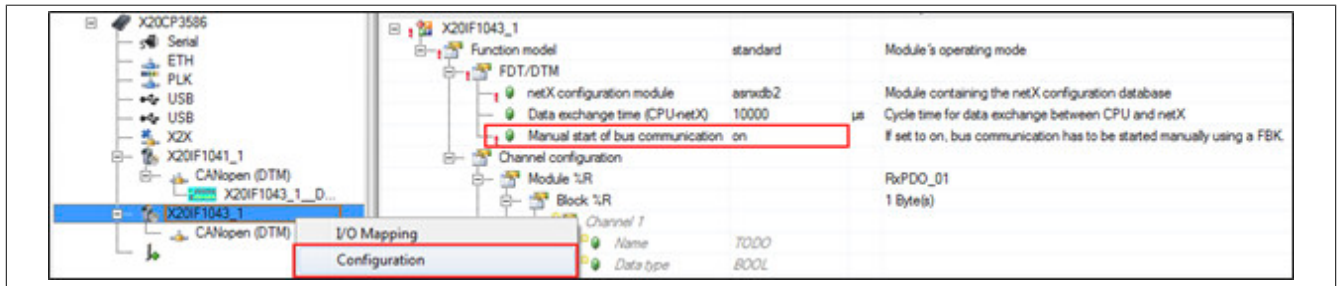

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

Information:

Parameter "Manual start of bus communication" can be enabled under the I/O configuration of the CANopen slave.

The following settings must be made in order to avoid automatic data exchange:

- In the IF module configuration, "Manual start of bus communication" must be set to "On".
- "Start of bus communication" must be set to "Controlled by application".

With this setting, communication can only be started via function block **AsNxCoS - nxcosStartBusComm()**.

- Device

This data is read from the EDS file (DTM) and not configurable.

- Vendor

This data is read from the EDS file (DTM) and not configurable.

Special function objects

The receipt of EMCY messages and transmission of SYNC messages can be set here. However, these settings can only be configured in the device description file on the master.

- Synchronization message

Whether the slave generates the SYNC messages can be set here.

Information:

On the slave, this setting causes an error message and is therefore not permitted to be used.

| Parameter | Explanation |
|-------------------------------|---|
| Device generates SYNC message | Enabling generation of the SYNC message |

No other parameters are supported.

- TimeStamp message

This parameter is not supported.

- Emergency message

Whether the master can receive EMCY messages can be set here.

| Parameter | Explanation |
|-------------|----------------------------------|
| EMCY exists | Master can receive EMCY messages |

No other parameters are supported.

Object dictionary

The object dictionary of the device is listed here. These are taken from the EDS file (DTM). PDO objects can be enabled or disabled in the object dictionary. This is done under "Process data objects - Properties" on page 2296.

The object dictionary can be filtered with "Area" and "Status"; using "Object", a single object can be searched.

| | | | | | | |
|-------|---------------|---------|-----|---------|--------|--|
| Area: | [1400 - 1FFF] | Status: | All | Object: | 0x1001 |  Go |
|-------|---------------|---------|-----|---------|--------|--|

Object dictionary

| Parameter | Explanation | Values |
|----------------|--|--|
| Configure | Overview of the configuration options. <ul style="list-style-type: none"> Key symbol: Entry cannot be configured in the object dictionary. Checkbox with check mark: Object can be configured. Checkbox without check mark: Object is locked for the configuration. | |
| Index.Subindex | Object address consisting of index and subindex | |
| Name | Symbolic name of the device | |
| Access | Access rights of the device | <ul style="list-style-type: none"> RO - Read only RW - Read and write WO - Write only CONST - Constant value |

When a specific object is selected in the object dictionary, the name, current value, default value, data type and minimum/maximum values of the object are listed. This listing can be in decimal and hexadecimal notation.

| | | |
|------------------|------------------------|-----------------------|
| Selected object: | 0181D.03 Inhibit Time | |
| Display mode: | Decimal | Data type: UNSIGNED16 |
| Current value: | Decimal Hexadecimal | Min: 0 |
| Default: | 0 | Max: 65535 |

Process data objects - Properties

Additional PDOs can be enabled here. Each additional PDO enabled is listed under "Process data objects → Mapping → PDO contents mapping for" and in the I/O mapping. The first 4 PDOs (0x1400 to 0x1404 for RxPDO and 0x1800 to 0x1804 for TxPDO) are enabled by default. To update the I/O mapping, additional PDOs must be enabled.

The PDO type can be used to toggle between transmit PDOs (TPDO) and receive PDOs (RPDO).

| Parameter | Explanation |
|-----------|---|
| Configure | Enables or disables a PDO for configuration and communication |
| Index | Object index of the PDO |
| PDO name | Name of the PDO |

If a PDO is selected in the table, the properties of the PDO are listed under the table.

- COB ID

The COB ID consists of the CAN identifier and additional parameters for the corresponding communication object.

| Parameter | Explanation | Values |
|---------------|--|-----------|
| CAN ID | CAN identifier of the object. | 1 to 2047 |
| PDO exists | This parameter is identical to enabling the PDOs in the table under "Configure". If this parameter was enabled, the affected PDO is present in the mapping. By default, only the first 4 PDOs are enabled. | |
| RTR permitted | If selected, the message trigger mode "Remotely requested" is permitted for this PDO. This means that when an RTR triggered by a PDO consumer is received, the transfer of an event-controlled PDO is triggered. Otherwise, message trigger mode "Remotely requested" is not permitted for this PDO. The value from the EDS file is applied as the default value. An RTR is not permitted to be used to query a transfer of emergency objects. | |
| 29-bit | This parameter is not supported. | |

- Transmission

The transfer type and rate are defined here.

| Parameter | Explanation | Values |
|-------------------|---|---|
| Transmission type | <p>For the transmit or receive PDOs, different transfer types are possible. A PDO can be configured for an event-driven, synchronous or asynchronous transfer. Transfer types can be synchronized, e.g. to the synchronization message SYNC, which is transmitted by the master in defined time intervals. Synchronous means that the transfer of the PDOs is related to the synchronization message. Asynchronous means that the transfer of the PDOs is not related to the SYNC synchronization message and can be executed at any time.</p> <p>Support for the different transfer types depends on the manufacturer and device. CANopen does not require support from individual or all transfer types. For information about whether a device supports the desired transfer type, check the device description of the device used.</p> | Synchronous acyclic (0) Synchronous cyclic (1 to 240) Event-controlled, manufacturer-specific (254) Event controlled, profile-specific (255) |
| Transmission rate | <p>For synchronous TPDOs, a number must be specified for transfer type "Synchronous cyclic (1 to 240)" to which the SYNC message of the data transfer refers.</p> <ul style="list-style-type: none"> A SYNC number of 1 indicates that the message is transferred with each SYNC synchronization message. A SYNC number of n indicates that the message is transferred with every nth SYNC synchronization message. <p>Asynchronous TPDOs are not transferred in any timing relationship with a SYNC synchronization message.</p> | 1 to 240 |
| Inhibit time | <p>It describes the minimum time period that must elapse between the sending of identical messages. This suppresses sending identical messages too frequently. This parameter is not supported.</p> | |
| Event timer | <p>Only for TPDOs transfer types 254 and 255. The expiration of the timer is used as an event to transmit the TPDO. Transmitting the TPDO and resetting the event timer can also be caused by an application event, however. This parameter is not supported.</p> | |

Process data objects - Mapping

The mapping can be configured here.

The PDO type can be used to toggle between transmit PDOs (TPDO) and receive PDOs (RPDO).

The table is divided into two parts. All usable objects are listed in the upper part. The lower part contains a list of the objects that have already been added to the mapping. It is added to the mapping by double-clicking on a PDO in the upper table.

| Parameter | Explanation |
|----------------|---|
| Index.Subindex | Index or subindex of the relevant object. |
| Parameter | Name of the object |
| Data type | Data type of the object |
| Length | Length of the PDO in bytes |
| Access | PDO access right |

The enabled PDOs can be toggled under "PDO contents mapping for". A maximum of 8 bytes, i.e. 64 bits, can be mapped in a PDO.

Information:

The number of mappable PDOs is limited. As soon as the limit has been reached, either an object must be removed or additional PDOs must be enabled under "[Process data objects - Properties](#)" on page 2296.

Address table

Contains a list of all PDOs that are categorized according to their inputs and outputs. The respective length of the inputs and outputs as well as the assigned address can be read in this table.

This table is not available in the EDS description file on the master.

"Display mode" allows toggling between decimal and hexadecimal display.

| Parameter | Explanation |
|----------------|--|
| PDO-Name | The RxPDO name or TxPDO name is displayed here. These are defined in the EDS file. |
| PDO-Idx | Object index of the process data object (PDO) |
| COB ID | COB ID of the CAN message |
| Obj.Idx Subidx | All objects are addressed in the object index and, if applicable, in the associated sub-indexes defined by the EDS file. |
| Obj.Name | Object name |
| Type | Type of input or output data |
| Length | Length of the input or output data of the PDO in bytes |
| Address | Offset address of the input or output data |

The address table can also be exported as a CSV file.

Device description

General device information and the entire EDS file can be read here.

9.23.5.8.2 EDS device description file

The module description is made available to the master in an EDS file. This file contains the description of the slave's complete range of functions. The EDS file can be downloaded from the B&R website (www.br-automation.com) in the Downloads section for the interface module and then imported into the respective master environment.

9.23.5.8.3 Configuration example

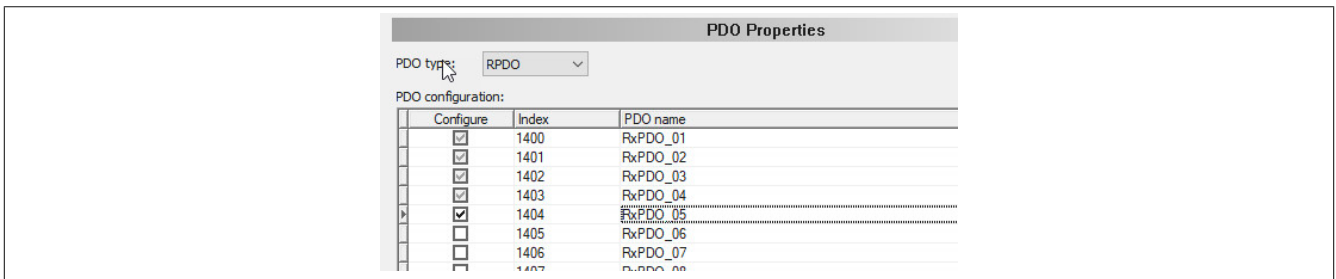

- In this example, the PDO mapping should be configured to 40 input bytes and 20 output bytes. "Device configuration" on the CANopen slave is opened for this.

- The number of RPDOs and TPDOs that must be applied is defined under "Process data objects → Properties". 8 bytes of data can be transferred per PDO. The minimum number of RPDOs and TPDOs is always 4, even if less data should be transferred.

RPDO

For 40 byte input data, 5 RPDOs are selected.

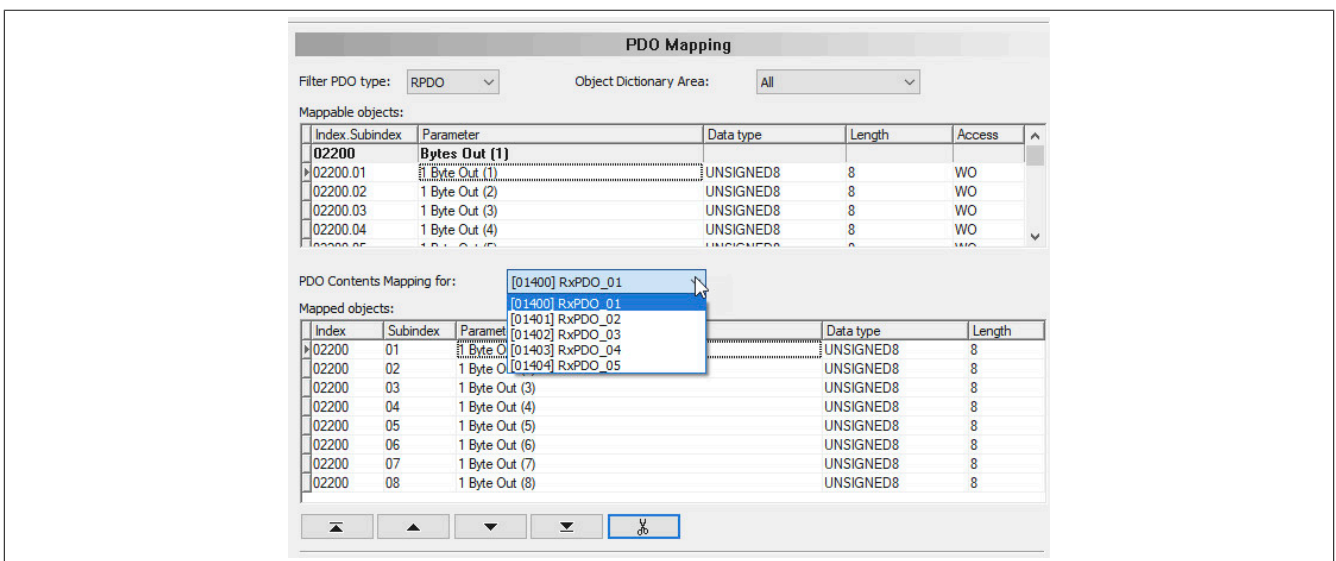

TPDO

To configure the TPDOs, "TPDO" is selected as the PDO type. Since only 20 bytes should be transferred, the default setting of 4 PDOs remains unchanged.

- The type of data transfer is defined (cyclic, acyclic, event-driven, etc.) under "Transmission type". For this example, the PDOs are transferred as "event-driven", i.e. only when data is changed.

- The PDOs are filled under "Process data objects → Mapping". The configured RPDOs are listed under "PDO contents mapping for"; in this example, they are listed as RPDO 1 to RPDO 5.

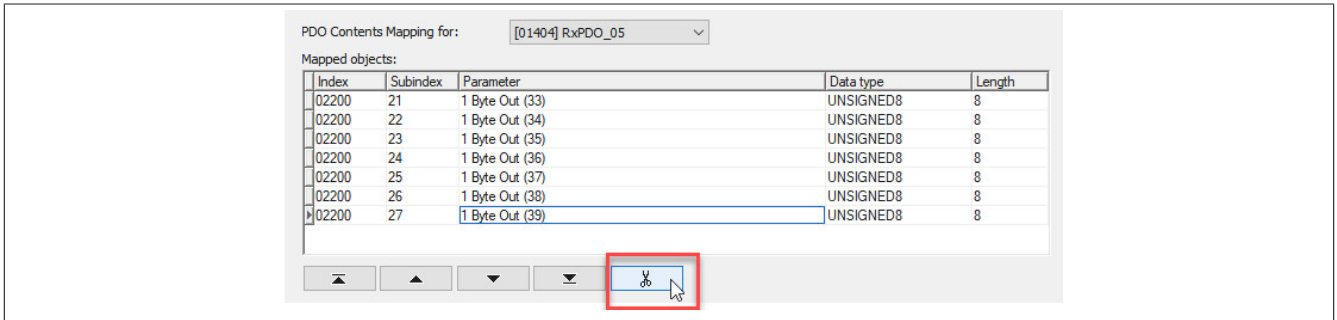

By default, the PDOs are filled with bytes. No change must therefore be made for the input bytes.

If a change is desired, RPDOs can be swapped out or data cut and pasted with "PDO contents mapping for".

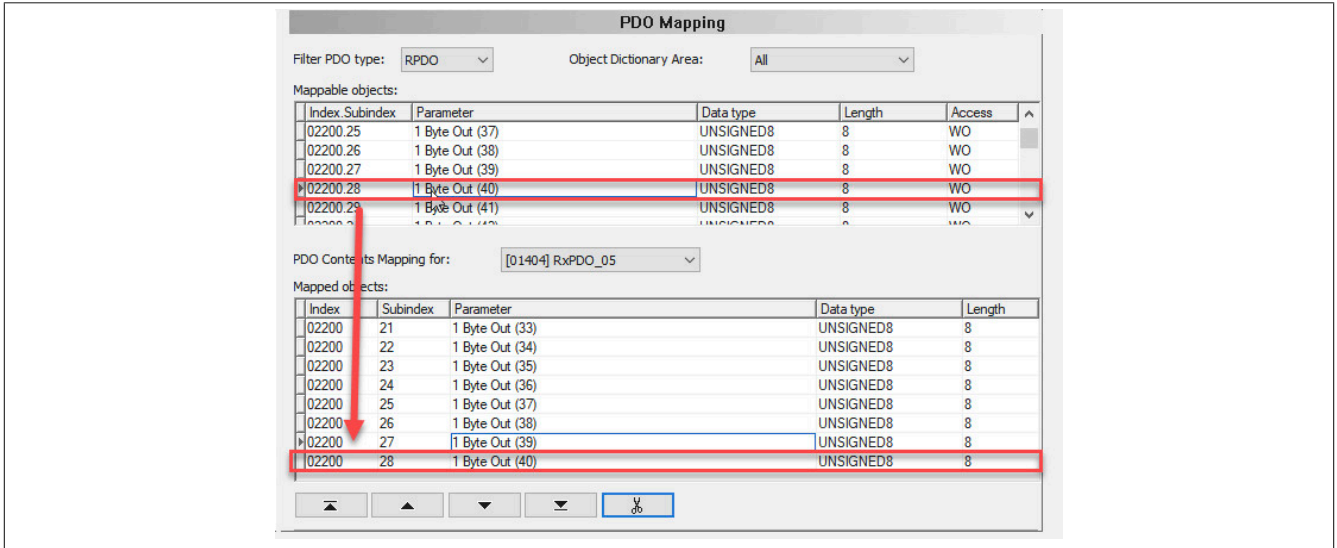

Cut

Select the desired object and cut it out with the scissors.

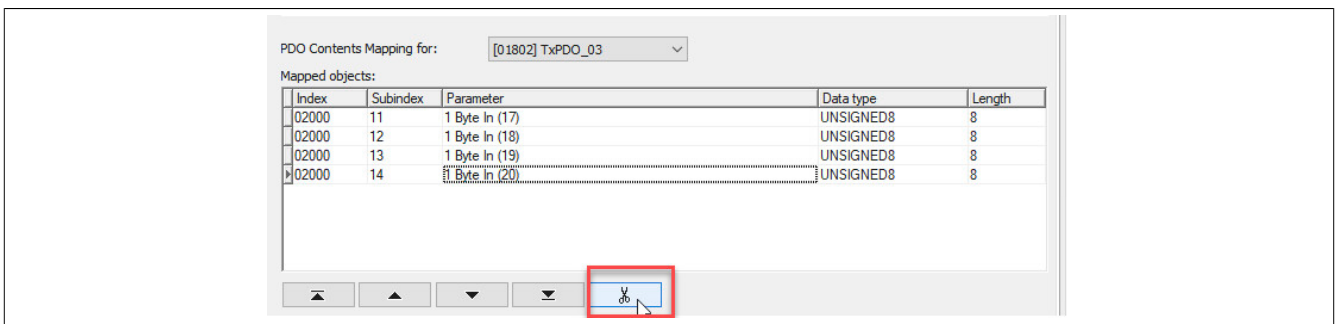

Paste

Double-clicking on an index in "Mappable objects" transfers the object to "Mapped objects".

- TPDOs are edited by changing to "TPDO" under "Filter PDO type". Bytes that are not required can be removed from the assignment. This is done by selecting the relevant TPDOs and cutting the superfluous objects using the scissors.

Because only 20 output bytes are needed in this example, no bytes are mapped in TPDO4 and only 4 bytes in TPDO3.

- Configuring the device description file

Identical settings must be made in the device description file. To do this, the device description file attached to the master must be set identically to the device configuration and I/O mapping of the CANopen slave.

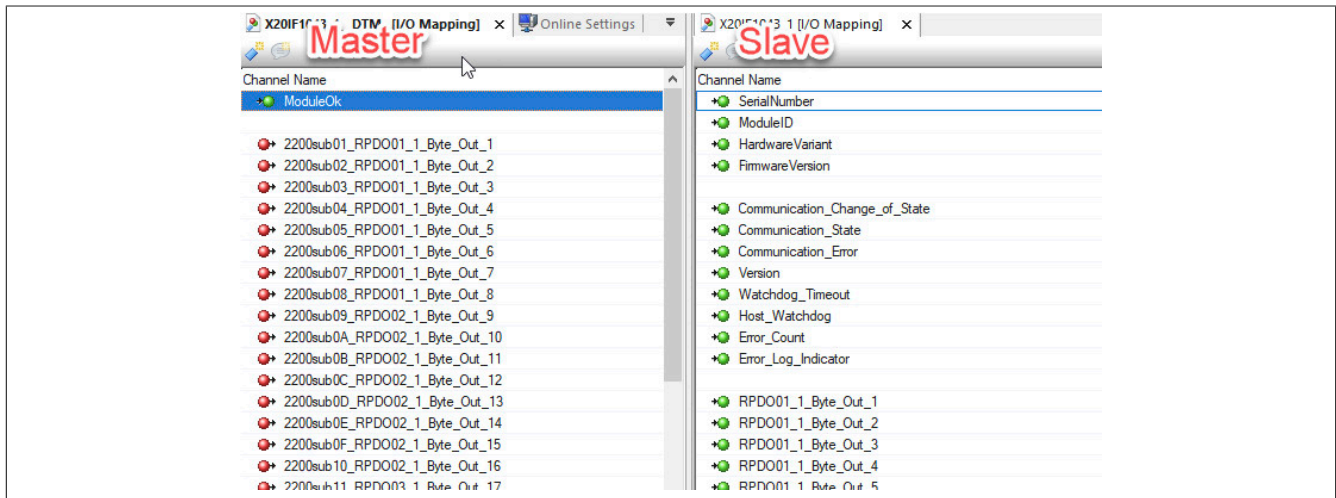

If the setting on the CANopen slave and the device description file attached to the master do not match, no connection is established.

Information:

The number of input and output bytes must be set identically on the master and slave. The direction of the data on the slave is applied in the direction opposite to the master since data exchange takes place in the opposite direction.

In the following example, this means:

- Device description file on the master: 40 bytes in the output direction and 20 bytes in the input direction.
- Slave: 40 bytes in the input direction and 20 bytes in the output direction.

9.23.6 X20IF1051-1

Data sheet version: 2.03

9.23.6.1 General information

The interface module is equipped with a DeviceNet scanner interface. This allows third-party components to be integrated in the B&R system and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

- DeviceNet scanner
- Integrated terminating resistor

9.23.6.2 Order data

| Model number | Short description | Figure |

Table 430: X20IF1051-1 - Technical data

9.23.6.4 Operating and connection elements

9.23.6.4.1 LED status indicators

| Figure | LED | Color | Status | Description |
|--------|-----------|-----------|------------------|---|
| | READY/RUN | Green/Red | Off | No power to module |
| | | Green | On | PCI bus communication in progress |
| | | Red | On | Communication on the PCI bus has not yet been started |
| | MOD/NET | Green/Red | Off | Module not supplied with power or not online |
| | | Green | Blinking | Module online but no I/O connection active |
| | | Green | On | Module online and I/O connection active ("operating") |
| | | Red | Blinking | The red LED blinks if at least one of the following errors has occurred: <ul style="list-style-type: none"> • Minor fault (recoverable fault) • Connection error • No DeviceNet supply voltage |
| | | On | | Critical fault or critical connection error (duplicate MAC ID, bus off or module defective) |
| | TxD | Yellow | Flickering or on | The module is transmitting data via the DeviceNet interface. |
| | TERM | Yellow | On | The terminating resistor integrated in the module is switched on. |

9.23.6.4.2 DeviceNet interface

The interface is a 5-pin multipoint connector. Terminal block 0TB2105 must be ordered separately.

| Interface | Pinout | | |
|--|----------|------------------------------|------------|
| <p>5-pin male multipoint connector</p> | Terminal | DeviceNet | |
| | 1 | CAN _⊥ (V-) | CAN ground |
| | 2 | CAN _L | CAN low |
| | 3 | SHLD | Shield |
| | 4 | CAN _H | CAN high |
| 5 | V+ | Supply voltage ¹⁾ | |

1) The 24 VDC in the DeviceNet network must be fed in externally in order to guarantee correct operation and data exchange. 24 VDC is not made available by the device.

9.23.6.4.3 Terminating resistor

A terminating resistor is integrated in the interface module. It can be switched on or off with a switch on the bottom of the housing. A switched-on terminating resistor is indicated by LED "TERM".

9.23.6.5 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.6.5.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.6.5.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision \geq E0 is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.6.6 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.6.7 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.6.8 The DeviceNet interface

The interface module is equipped with a DeviceNet scanner interface. Up to 63 slaves can be operated on the master.

UCMM (Unconnected Message Manager) is supported.

Poll, change of state, cyclic, bit strobe and explicit peer-to-peer messaging are supported as connection types.

9.23.6.8.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

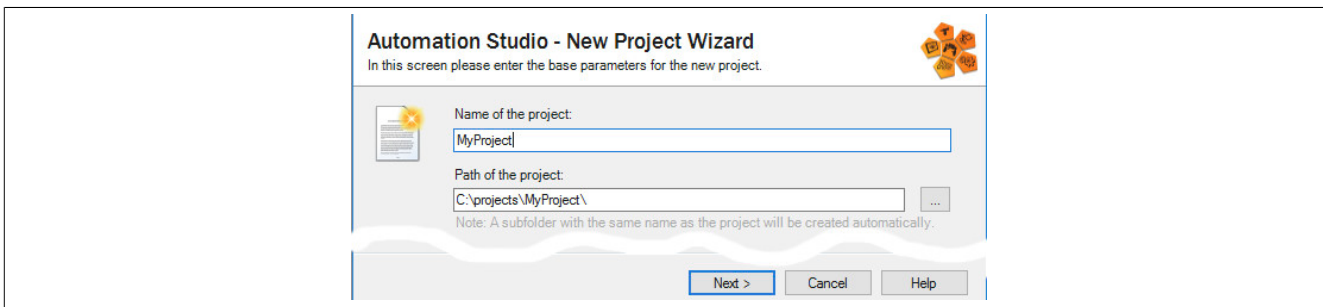

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.6.8.1.1 Creating an Automation Studio project

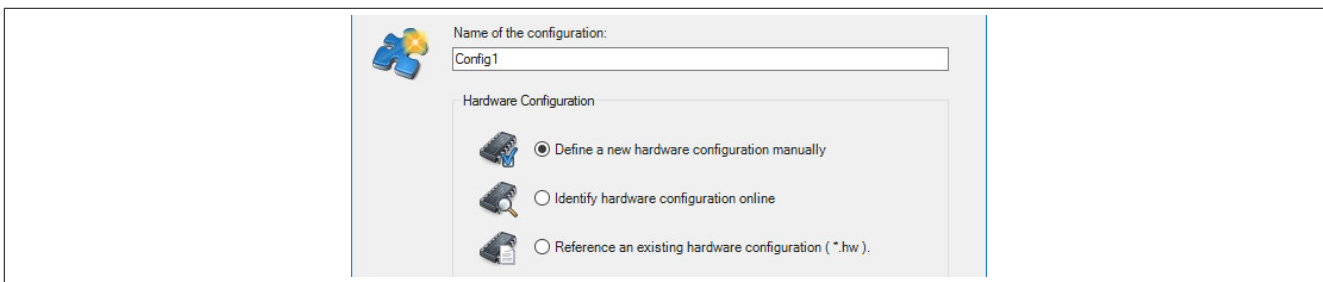

- Create a new Automation Studio project by selecting "New project".

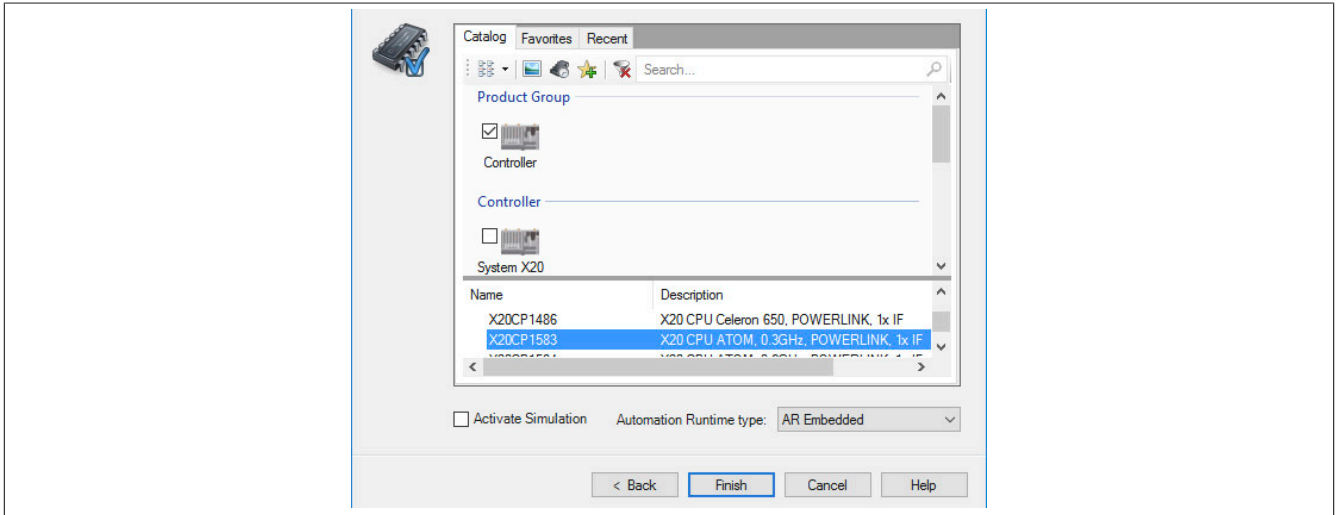

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

9.23.6.8.1.2 Adding and configuring the interface module

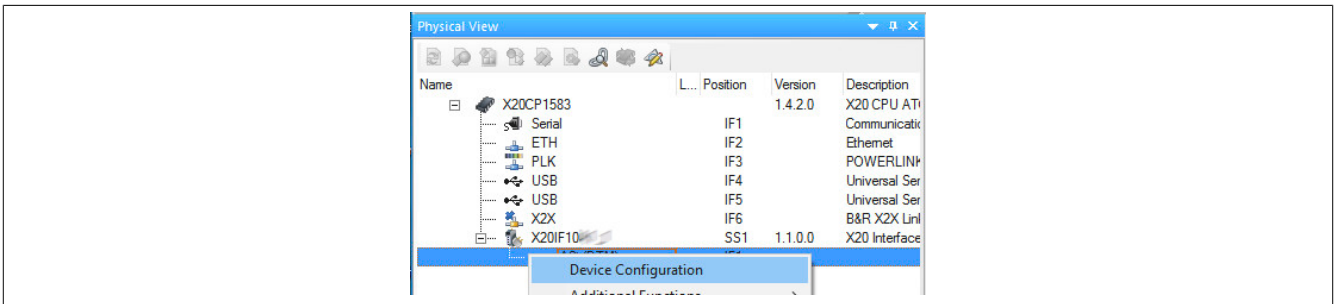

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

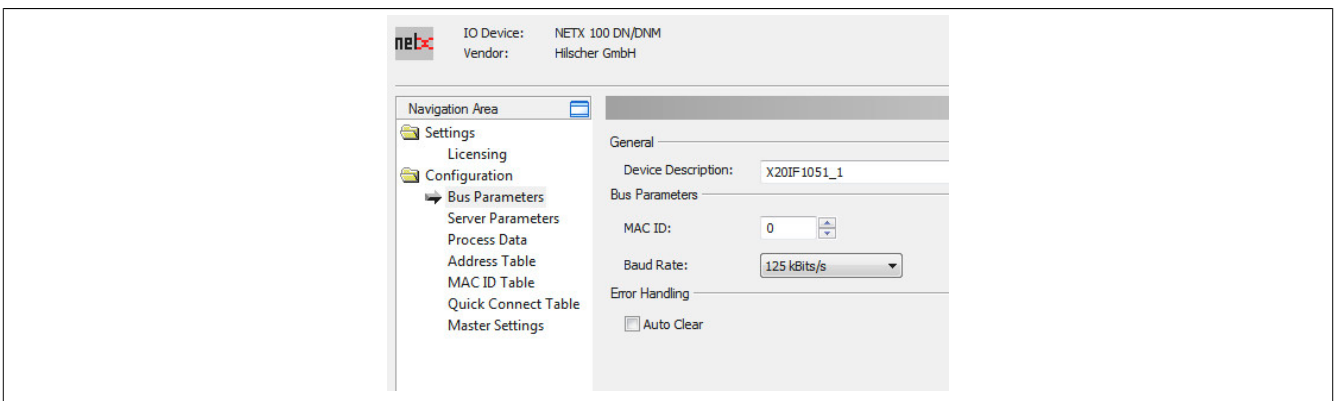

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

Bus parameters

- General

The name of the device can be changed here. However, this is only used by the configuration dialog boxes and not by Automation Studio.

- Bus parameters

The MAC ID and baud rate can be set here.

- The MAC ID serves as the unique identification for a DeviceNet device in the network and is not permitted to be used twice. The range of values for available MAC IDs is between 0 and 63.
- The baud rate can be set between 125 and 500 kbit/s.

- Error handling

"Auto clear" ON is used for error handling.

| Parameter | Explanation |
|-----------|--|
| Enabled | The master changes to mode "Clear" first in the event of a communication error and then to mode "Stop". Communication to all slaves is stopped. The only way to exit mode "Stop" is by resetting the system. |
| Disabled | The master remains in mode "Operate" in the event of a communication error. The master is still connected to the other slaves and attempts to reestablish communication with the defective or missing slave. |

Server parameters

This parameter is not supported.

Process data

This table lists the process data of the individual slaves.

| Parameter | Explanation |
|-----------|---|
| Type | Device designation specified by the hardware. Further description of modules configured on the device or the input or output signals. |
| Tag | The name of the input and output data can be changed in column "Tag". |
| SCADA | This parameter is not supported. |

Address table

This table provides information about the addresses of the input and output data. If auto-addressing is disabled, addresses can be entered manually.

| Parameter | Explanation |
|-----------------|--|
| MAC ID | Network address of the device |
| Device | Device name of the slave |
| Name | Description of slave |
| Connection mode | Mode for the input and output data |
| Length | Length of the input and output data |
| Address | Address offset for the input and output data |

The input and output address table can also be exported as a CSV file.

Information:

Using the same address twice is not permitted. Addresses used twice are marked with a red exclamation point and an additional error message is displayed.

MAC ID table

All slaves are listed here. "Activate" is used to activate or deactivate the slaves.

| Parameter | Explanation |
|-----------|--|
| Activate | <ul style="list-style-type: none"> Enabled slaves: Process memory is reserved and data is exchanged. It is also possible to assign the slave a different MAC ID. Deactivated slaves: The master reserves memory in the process data image for the slave, but no data is exchanged. |
| MAC ID | Editable network address of the device. The new MAC ID must be unique; otherwise, an error message will appear. |
| Device | Device name of the slave |
| Name | Description of slave |
| Vendor | Slave manufacturer |

Quick connect table

This function allows for a quick startup of a device after it is replaced.

| Parameter | Explanation | Values |
|---------------|---|---------|
| Quick connect | Function "Quick connect" must be enabled separately for each slave. The following system requirements must be met in order to optimally use "Quick connect": <ul style="list-style-type: none"> The master must support "Quick connect". Additionally, the slave must support "UCMM" or "Predefined master/slave connection." | |
| MAC ID | Network address of the device. | 0 to 63 |
| Device | Device name of the slave and the EDS file | |
| Name | Name of the slave and the EDS file | |

Depending on the type of quick connect support, the following times may apply:

| Quick connect support | | Time to connect |
|-----------------------|-------|------------------|
| Master | Slave | |
| Yes | Yes | Under 200 ms |
| Yes | No | Approx. 2 s |
| No | Yes | Approx. 2 to 3 s |
| No | No | Approx. 2 to 5 s |

Master settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

- Module alignment

The addressing mode is defined by the process image here. The addresses (offsets) of the process data are always interpreted as byte addresses.

| Addressing mode | Explanation |
|-------------------|---|
| Byte boundaries | The module address can start on any offset. |
| 2 byte boundaries | The module address can only start on even byte offsets. |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|-----------------------------|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values | 20 to 65535 ms |
| | Default value: 1000 ms | |

Information:

The watchdog time is reset automatically by Automation Runtime.

- Process data handshake

This parameter configures the handshake for the data exchange between application and device. Only "Buffered, host-controlled" is supported here.

- Advanced

This parameter is not supported.

- Device status offset

Here, the status offset can be set to be calculated automatically or using a predefined value.

| Status offset | Explanation |
|-----------------------|---|
| Automatic calculation | The device status always directly follows the input bytes. If input data is added in the configuration, the start address of the device status is moved back in the dual-ported memory. |
| Static | <p>Here, the distance (free buffer) between the last input byte and the start of the device status can be set. This way, the start address of the device status never changes in the dual-ported memory. If additional input data is added, the distance (free buffer) is reduced. If the free buffer does not have enough space available for the data added to it, the start address of the device status in the dual-ported memory must be shifted.</p> <p>If the offset is too small, an error is output. To correct the error, the free buffer must be increased to a sufficient size.</p>  |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

9.23.6.8.1.3 I/O mapping

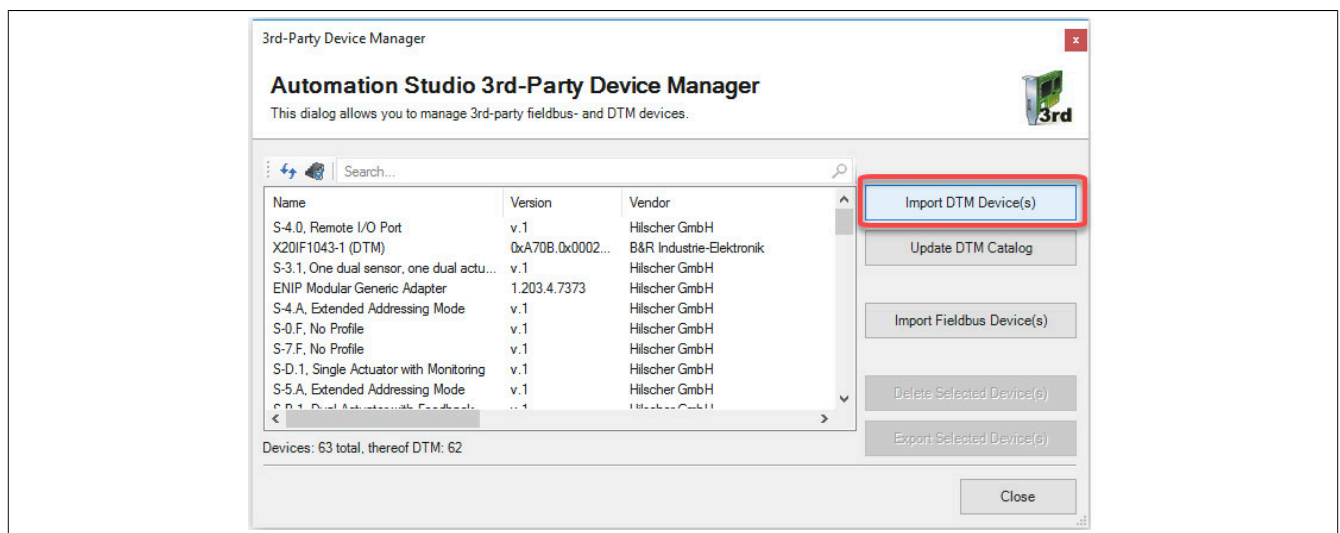

The I/O mapping resulting from the module configuration is opened by double-clicking on the DeviceNet master. General information such as the serial number and module ID are listed in the mapping along with DeviceNet-specific data points.

9.23.6.8.1.4 Adding the EDS file in Automation Studio

A device description file (EDS file) is required to inform the DeviceNet master which slaves were connected and how they were configured.

To add and use a device description file in Automation Studio, perform the following steps:

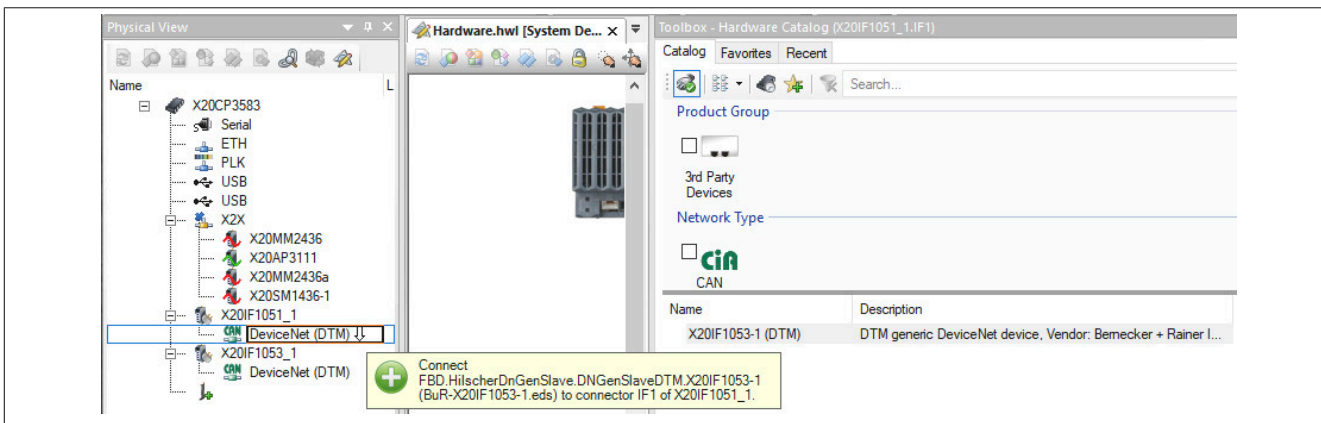

- If the DeviceNet slave from B&R is used, download the EDS file from the B&R website (www.br-automation.com) and unzip the ZIP file.
- Open the dialog box in Automation Studio under "Tools - Manage 3rd-party devices" and select "Import DTM device(s)".

- Select the EDS file to be imported and confirm with OK. The EDS file is imported into Automation Studio.

- Click "DeviceNet(DTM)" on the DeviceNet master X20IF1051-1, drag the EDS file from the Hardware Catalog and attach it to the DeviceNet master.

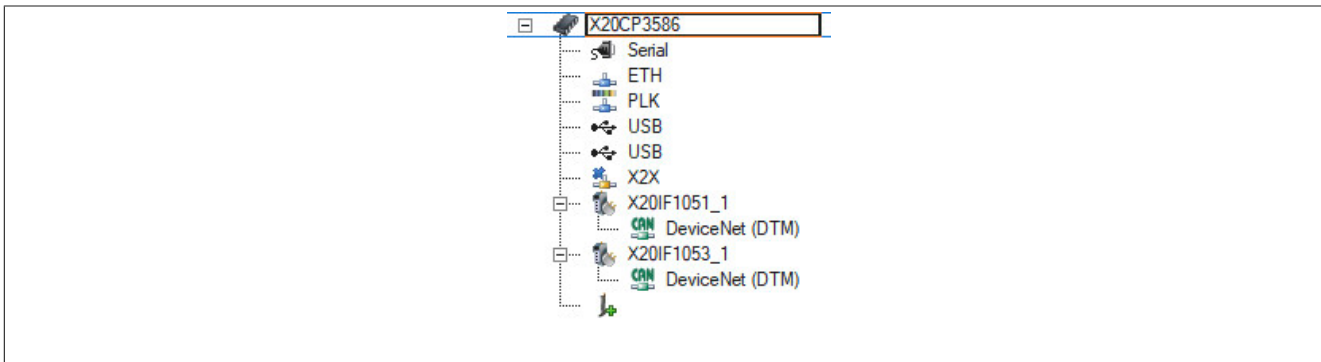

- Right-click on the device description file and select "Device configuration" to open the configuration environment for the EDS file.

9.23.6.8.2 Configuration example

In this example, a connection between a DeviceNet master and slave is established. Module X20IF1051-1 is used as the DeviceNet master; module X20IF1053-1 is used as the DeviceNet slave.

For this example, the DeviceNet master interface card is operated in the first slot of an X20CP3586 and the DeviceNet slave interface card in the second slot.

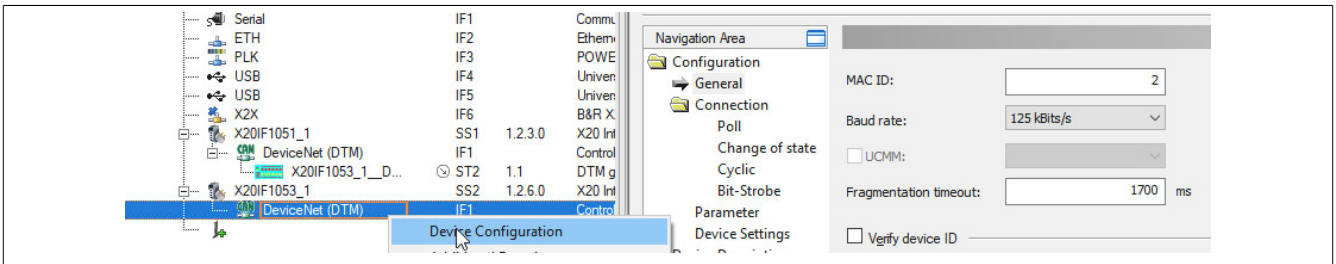

- To establish a connection between master and slave, the master must know the configuration data of the slave. To do this, the device description file of the X20IF1053-1 slave is imported into Automation Studio and attached to the master.

For details, see "Adding the EDS file in Automation Studio" on page 2311.

The settings on the DeviceNet slave and on the master (device description file) must match; otherwise, no connection is established.

Settings on the slave

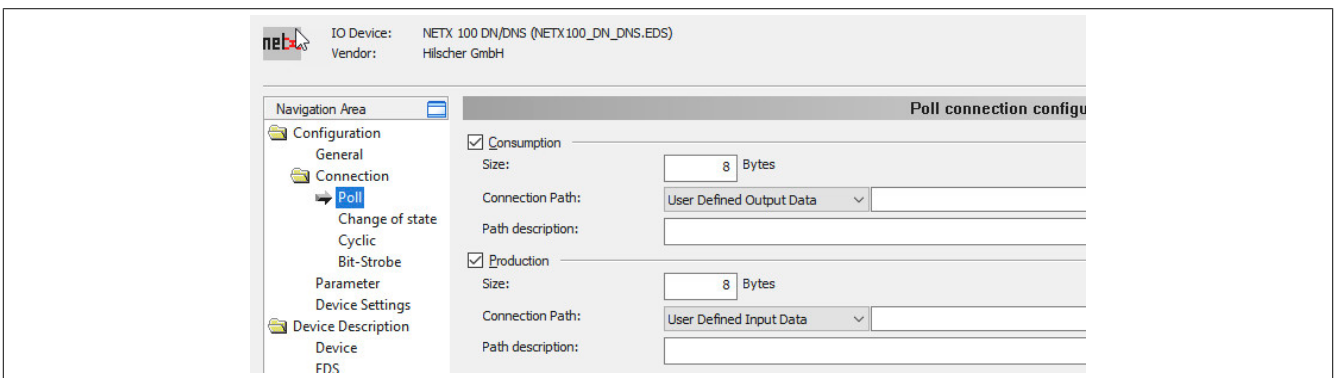

- In this example, the MAC ID "2" and a baud rate of 125 kbit/s were defined for the slave. These are set in "Device configuration" under "General" on the slave.

- Next, the connection type and I/O mapping are each defined with 8 bytes of input and output data. "Poll connection" is enabled in the "Connection" configuration.

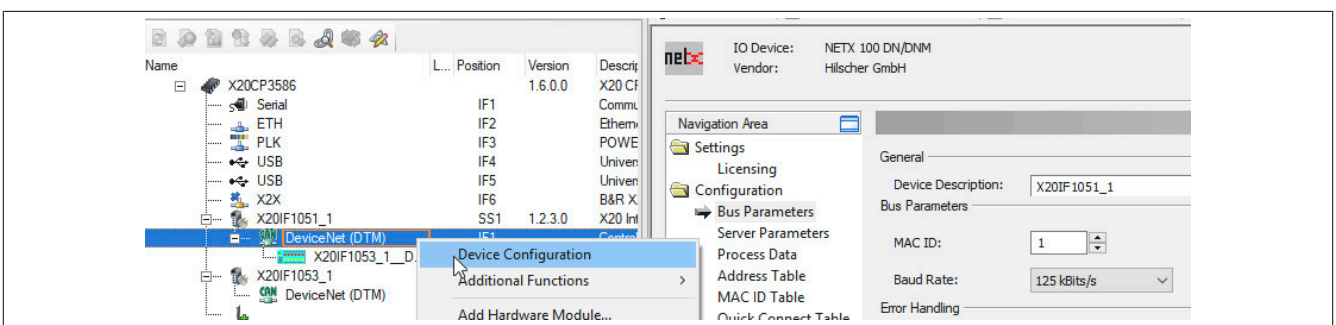

- Under "Poll connection configuration", 8 bytes each are entered for the input and output directions.

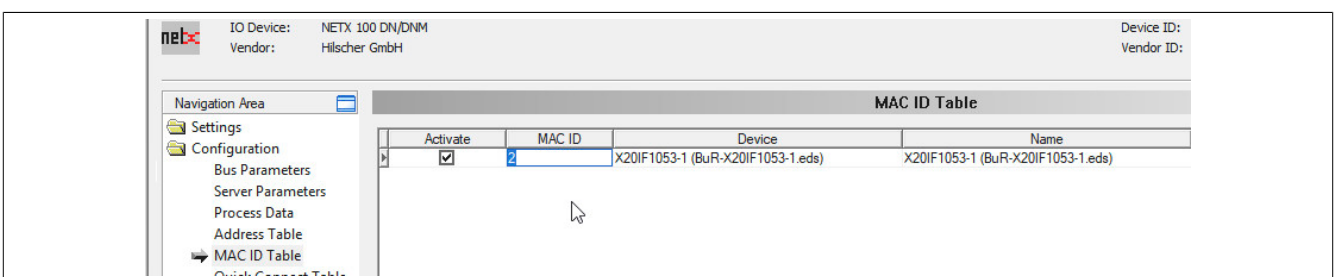

Settings on the master

- On the master, the MAC ID and the same baud rate as on the slave must be set. These are set in "Device configuration" under "Bus parameters".

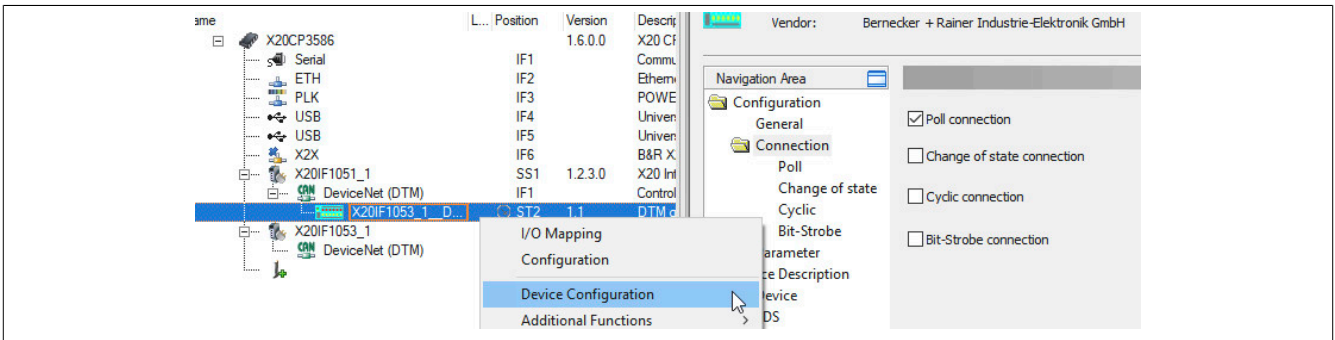

- Then the MAC ID of the slave is set under "MAC ID table".

Settings in the device description file

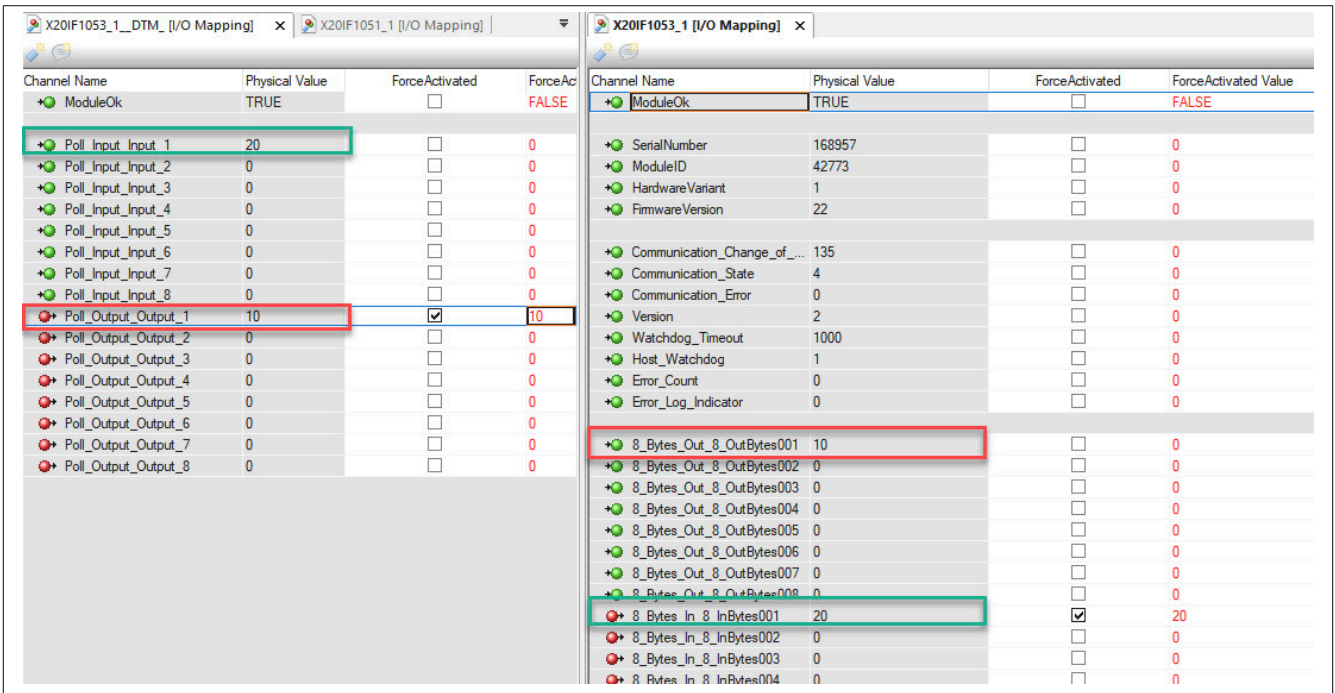

- The I/O mapping is set in the device description file under "Device configuration". The same settings are made here as on the DeviceNet slave.

By default, 8 bytes of input and output data are defined. If a different number of bytes should be set, the "Connection path" must be changed to "User defined consumption data".

- Confirm and save all settings with OK. The configuration is transferred to the CPU and, if correct, a connection between master and slave is automatically established.

The connection status can be checked with the ModulOK bit in the device description file. When ModulOK = True, data can be exchanged between master and slave.

9.23.7 X20IF1053-1

Data sheet version: 2.03

9.23.7.1 General information

The interface module is equipped with a DeviceNet interface. This allows the B&R system (I/O modules, POWERLINK, etc.) to be connected to systems from other manufacturers and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

- DeviceNet slave (adapter)
- Integrated terminating resistor

9.23.7.2 Order data

| Model number | Short description | Figure |

Table 432: X20IF1053-1 - Technical data

9.23.7.4 Operating and connection elements

9.23.7.4.1 LED status indicators

| Figure | LED | Color | Status | Description |
|--------|-----------|-----------|---|---|
| | READY/RUN | Green/Red | Off | No power to module |
| | | Green | On | PCI bus communication in progress |
| | | Red | On | Communication on the PCI bus has not yet been started |
| | MOD/NET | Green/Red | Off | Module not supplied with power or not online |
| | | Green | Blinking | Module online but no I/O connection active |
| | | | On | Module online and I/O connection active ("operating") |
| | | Red | Blinking | The red LED blinks if at least one of the following errors has occurred: <ul style="list-style-type: none"> • Minor fault (recoverable fault) • Connection error • No DeviceNet supply voltage |
| | | On | Critical fault or critical connection error (duplicate MAC ID, bus off or module defective) | |
| | TxD | Yellow | Flickering or on | The module is transmitting data via the DeviceNet interface. |
| | TERM | Yellow | On | The terminating resistor integrated in the module is switched on. |

9.23.7.4.2 DeviceNet interface

The interface is a 5-pin multipoint connector. Terminal block 0TB2105 must be ordered separately.

| Interface | Pinout | | |
|--|----------|-----------------------|------------------------------|
| <p>5-pin male multipoint connector</p> | Terminal | DeviceNet | |
| | 1 | CAN _L (V-) | CAN ground |
| | 2 | CAN _L | CAN low |
| | 3 | SHLD | Shield |
| | 4 | CAN _H | CAN high |
| | 5 | V+ | Supply voltage ¹⁾ |

1) The 24 VDC in the DeviceNet network must be fed in externally in order to guarantee correct operation and data exchange. 24 VDC is not made available by the device.

9.23.7.4.3 Terminating resistor

A terminating resistor is integrated in the interface module. It can be switched on or off with a switch on the bottom of the housing. A switched-on terminating resistor is indicated by LED "TERM".

9.23.7.5 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.7.5.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.7.5.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.7.6 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.7.7 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.7.8 The DeviceNet interface

The interface module is equipped with a DeviceNet slave (adapter) interface. Explicit messaging is supported. Poll, change of state, cyclic and bit-strobe are supported as connection types.

Information:

Neither UCMM nor quick connect are supported.

Information:

The settings on the slave must match the settings of the corresponding device description file; otherwise, no connection can be established.

9.23.7.8.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

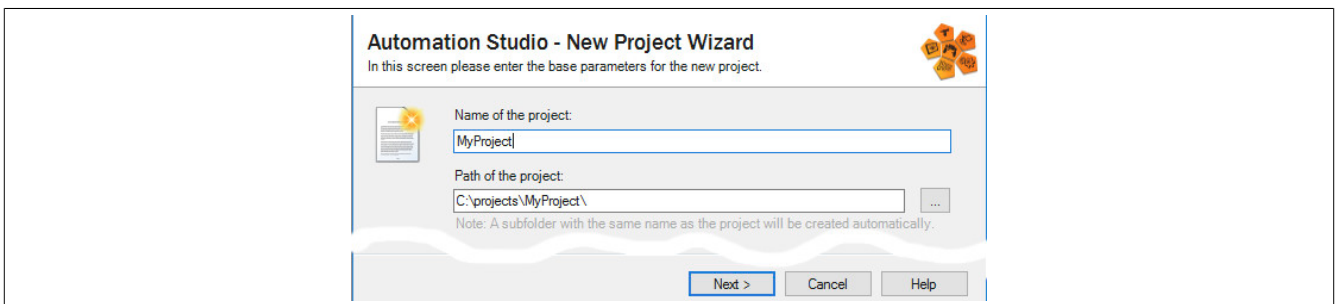

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.7.8.1.1 Creating an Automation Studio project

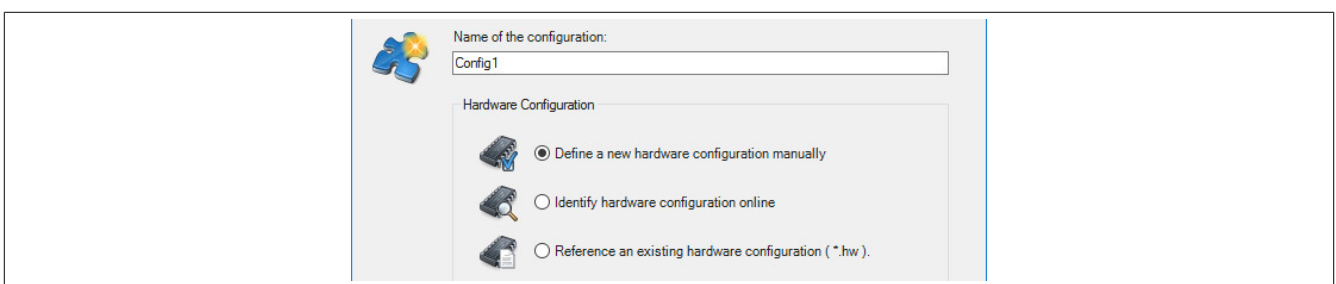

- Create a new Automation Studio project by selecting "New project".

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

9.23.7.8.1.2 Adding and configuring the interface module

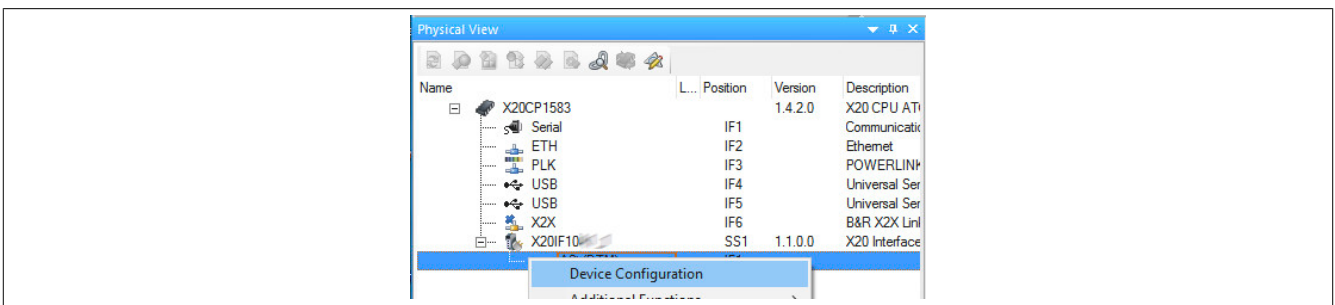

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

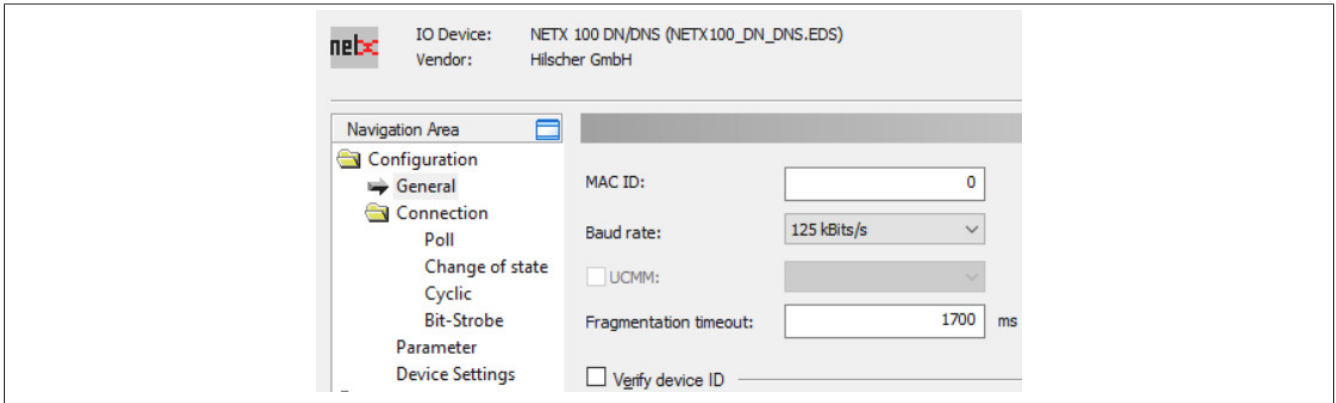

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

Information:

The settings of the slave must match the settings of the corresponding EDS device description file; otherwise, no connection can be established.

General

General settings are configured here.

- MAC ID

This serves as the unique identification for a DeviceNet device in the network and is not permitted to be used twice. The range of values for available MAC IDs is between 0 and 63.

Information:

MAC ID addresses must be the same for both the master (device description file) and slave.

- Baud rate

This rate can be set between 125 and 500 kbit/s.

- Fragmentation timeout

This parameter defines how long the master waits until a slave answers a fragmented telegram.

- UCMM

This parameter is not supported.

- Verify device ID

This enables a comparison of the device description file with the existing hardware. The comparison only applies to the attributes selected in this area.

- Enable address switch

This parameter is not supported.

Connection

The connection type between master and slave can be selected here. The corresponding tab for additional configuration options can be activated by enabling a connection type.

All possible combinations are listed under "Valid combinations". If a combination is invalid, a corresponding error message will be sent.

Configure connection type

There is a tab marked with the respective name of the connection type (e.g. "Poll") that can be opened for additional settings. When selecting multiple connection types, Automation Studio generates a combination of the selected connection types. The inputs and outputs of ALL connection types are then combined in a single process image.

Information:

When combining connections, the number of inputs and outputs must be identical for all individual connection types.

A different number of inputs or outputs for the connection types results in an error message on the slave.

Example

| Connection | Inputs/Outputs | Resulting process image | Inputs/Outputs | Resulting process image |
|--------------------|-------------------------|-------------------------|-------------------------|------------------------------|
| Change of state: | 10 inputs and 8 outputs | 10 inputs and 8 outputs | 10 inputs and 8 outputs | Results in an error message. |
| Cyclic connection: | 10 inputs and 8 outputs | | 10 inputs and 7 outputs | |

Connecting the slave with the master

The used inputs and outputs must be defined on the slave as well as in the device description file for this. If multiple connection types are selected on the slave, the inputs and outputs of all used connection types are listed as one single process image (see above). In the device description file on the master, however, the inputs and outputs are listed separately in the I/O mapping for each connection type.

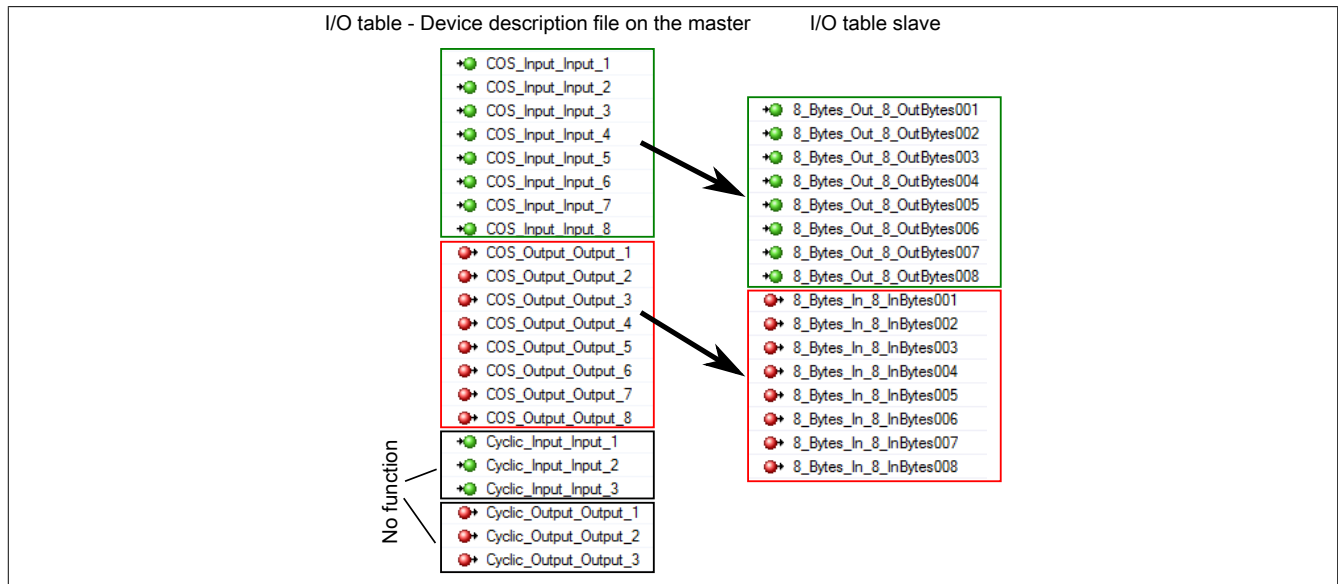

To ensure that the connection works properly, the following points must be observed:

- The number of defined inputs and outputs should be identical in the device description file and on the slave due to the fact that only the inputs and outputs defined on the slave are evaluated.
 - If there are more inputs or outputs in the device description file, these are ignored.
 - If there are less inputs or outputs in the device description file, the inputs or outputs on the slave remain without a function.
- Connection type "Bit strobe" only works via function block **AsNxDnM - AcyclicBitStrobing**. "Bit strobe" must also be enabled on the slaves.

Example

The change of state and cyclic connections are each set on the slave with 8 inputs and 8 outputs. In the device description file on the master, the change of state connection is specified with 8 inputs and 8 outputs. The cyclic is specified with 3 inputs and 3 outputs.

The image shows the generated and evaluated data points:

Information:

The number of connection types used is only determined by the slave. Therefore, only the inputs and outputs of one connection type should be defined in the device description file.

The following settings can be assigned for each connection type.

- Length of the input and output data

The maximum length is 255 bytes; for bit strobes, it is 8 bytes.

- Timing

| Parameter | Explanation |
|-------------------------|---|
| Production inhibit time | This parameter sets the time (in ms) within which identical telegrams are not permitted to be sent. This can be used to avoid sending identical telegrams too frequently and to reduce the bus load. A new telegram is only permitted to be sent after the delay time has expired. Examples Value 0: Telegrams can be sent without delay. Value 1000 in polling connection mode: A poll request telegram is sent every second (1000 ms). This parameter is not available for every connection type. |
| Expected packet rate | This parameter is always transmitted before an I/O transfer. If there is no response from the remote station within 4 times the time of the transmitted value, a timeout error occurs for the connection. |
| Watchdog timeout action | This parameter defines the behavior of the slave if the watchdog ("Expected packet rate") in the module has expired. <ul style="list-style-type: none"> Timeout: The connection goes into a timeout state and remains in this state until the connection is reset or deleted. Auto reset: The connection remains established and immediately resets the watchdog. Auto delete: The connection is deleted when a timeout occurs. |

Parameter

This parameter is not supported.

Device settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

Information:

Parameter "Manual start of bus communication" can be enabled under the I/O configuration of the DeviceNet slave.

The following settings must be made in order to avoid automatic data exchange:

- In the IF module configuration, "Manual start of bus communication" must be set to "On".
- "Start of bus communication" must be set to "Controlled by application".

With this setting, the communication can only be started via function block **AsNxDnS - nxdnsStartBusComm**.

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|-----------------------------|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values | 20 to 65535 ms |
| | Default value: 1000 ms | |

Information:

The watchdog time is reset automatically by Automation Runtime.

Device description

Device

This table displays the manufacturer information as defined in the EDS file.

EDS

The contents of the EDS file can be viewed and searched here.

9.23.7.8.1.3 I/O mapping

The I/O mapping resulting from the module configuration is opened by double-clicking on the DeviceNet slave.

9.23.7.8.2 EDS device description file

The module description is made available to the master in an EDS file. This file contains the description of the slave's complete range of functions. The EDS file can be downloaded from the B&R website (www.br-automation.com) in the Downloads section for the interface module and then imported into the respective master environment.

9.23.7.8.3 Configuration example

In this example, a connection between a DeviceNet master and slave is established. Module X20IF1051-1 is used as the DeviceNet master; module X20IF1053-1 is used as the DeviceNet slave.

For this example, the DeviceNet master interface card is operated in the first slot of an X20CP3586 and the DeviceNet slave interface card in the second slot.

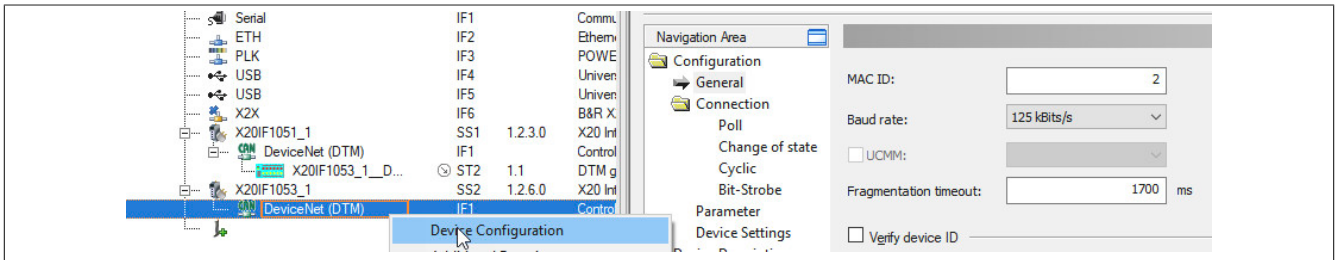

- To establish a connection between master and slave, the master must know the configuration data of the slave. To do this, the device description file of the X20IF1053-1 slave is imported into Automation Studio and attached to the master.

For details, see X20IF1051-1 "Adding the EDS file in Automation Studio" on page 2311.

The settings on the DeviceNet slave and on the master (device description file) must match; otherwise, no connection is established.

Settings on the slave

- In this example, the MAC ID "2" and a baud rate of 125 kbit/s were defined for the slave. These are set in "Device configuration" under "General" on the slave.

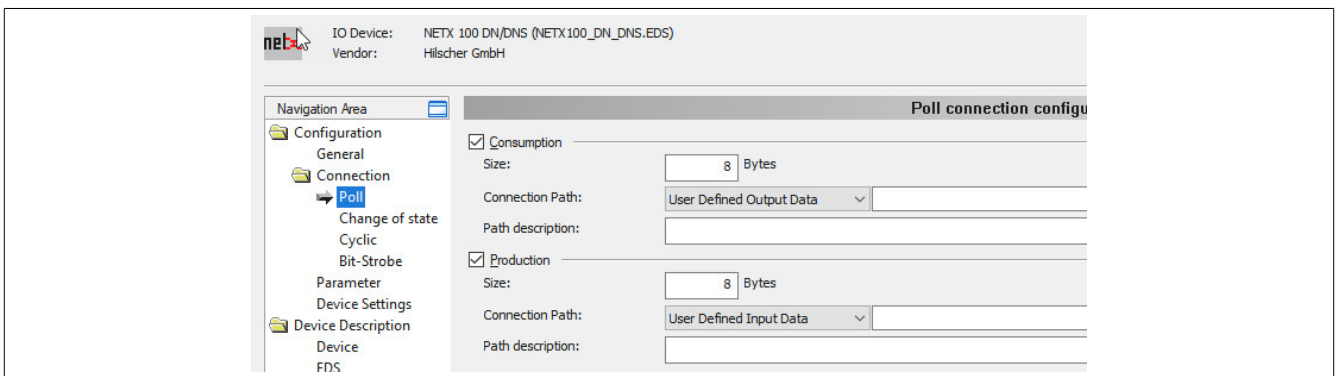

- Next, the connection type and I/O mapping are each defined with 8 bytes of input and output data.

"Poll connection" is enabled in the "Connection" configuration.

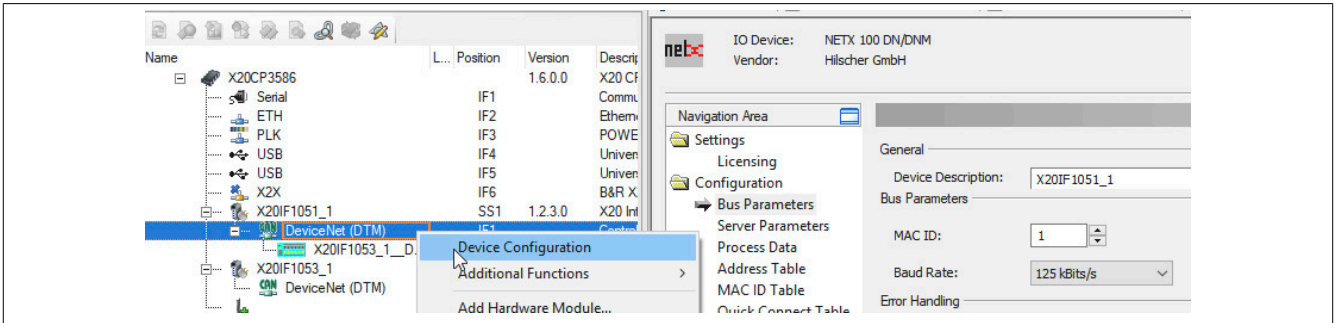

- Under "Poll connection configuration", 8 bytes each are entered for the input and output directions.

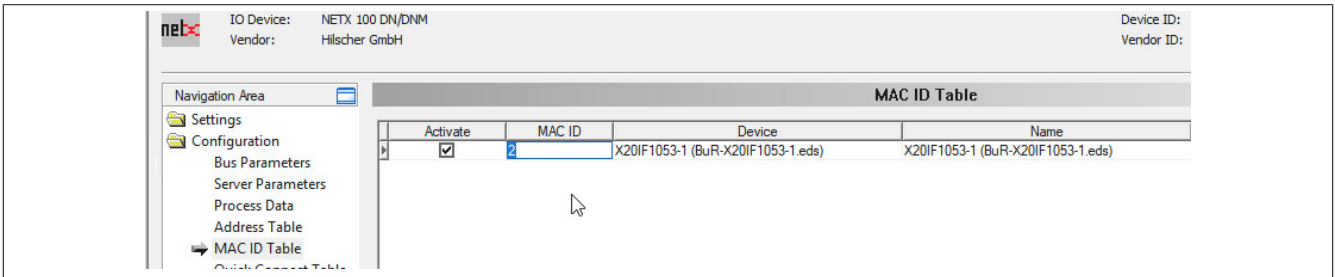

Settings on the master

- On the master, the MAC ID and the same baud rate as on the slave must be set. These are set in "Device configuration" under "Bus parameters".

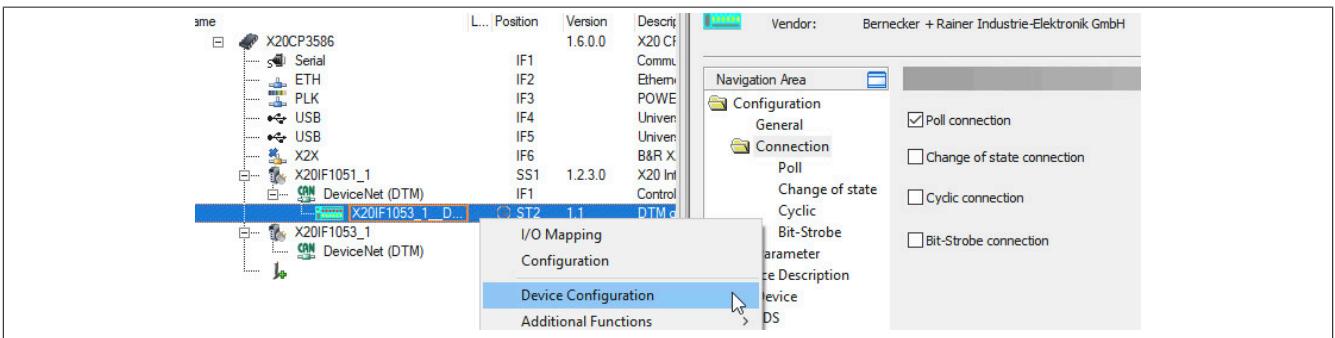

- Then the MAC ID of the slave is set under "MAC ID table".

Settings in the device description file

- The I/O mapping is set in the device description file under "Device configuration". The same settings are made here as on the DeviceNet slave.

By default, 8 bytes of input and output data are defined. If a different number of bytes should be set, the "Connection path" must be changed to "User defined consumption data".

- Confirm and save all settings with OK. The configuration is transferred to the CPU and, if correct, a connection between master and slave is automatically established.

The connection status can be checked with the ModulOK bit in the device description file. When ModulOK = True, data can be exchanged between master and slave.

| Channel Name | Physical Value | ForceActivated | ForceAc |
|----------------------|----------------|-------------------------------------|---------|
| ModuleOk | TRUE | <input type="checkbox"/> | FALSE |
| Poll_Input_Input_1 | 20 | <input type="checkbox"/> | 0 |

9.23.8 X20(c)IF1061-1

Data sheet version: 2.06

9.23.8.1 General information

The interface module is equipped with a PROFIBUS DP V1 interface. This allows third-party components to be integrated in the B&R system and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

- PROFIBUS DP V1 master

9.23.8.1.1 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.8.1.1.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.23.8.2 Order data

| Model number | Short description | Figure |

9.23.8.5 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.8.5.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.8.5.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision \geq E0 is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.8.6 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.8.7 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.8.8 Minimum DTM version for coated modules

Information:

The minimum DTM version required for coated modules is 1.0370.140220.12186. This version is included starting with Automation Studio upgrade packs V4.0.18.x and V3.0.90.29.

9.23.8.9 PROFIBUS DP interface

9.23.8.9.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

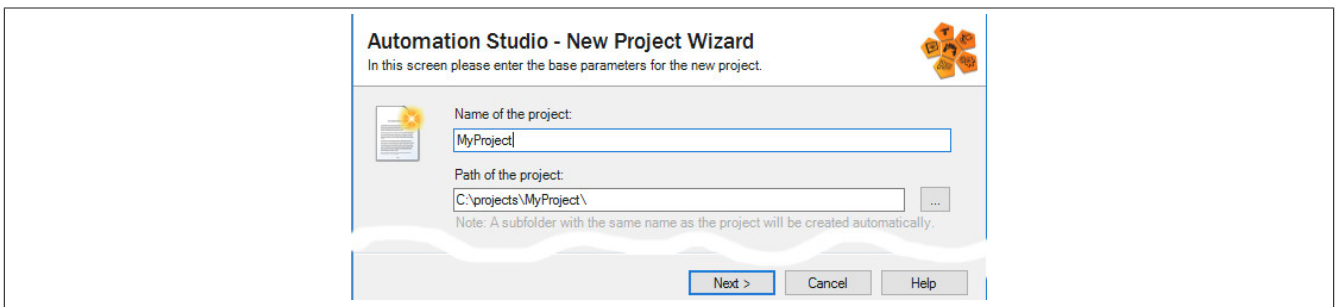

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.8.9.1.1 Creating an Automation Studio project

- Create a new Automation Studio project by selecting "New project".

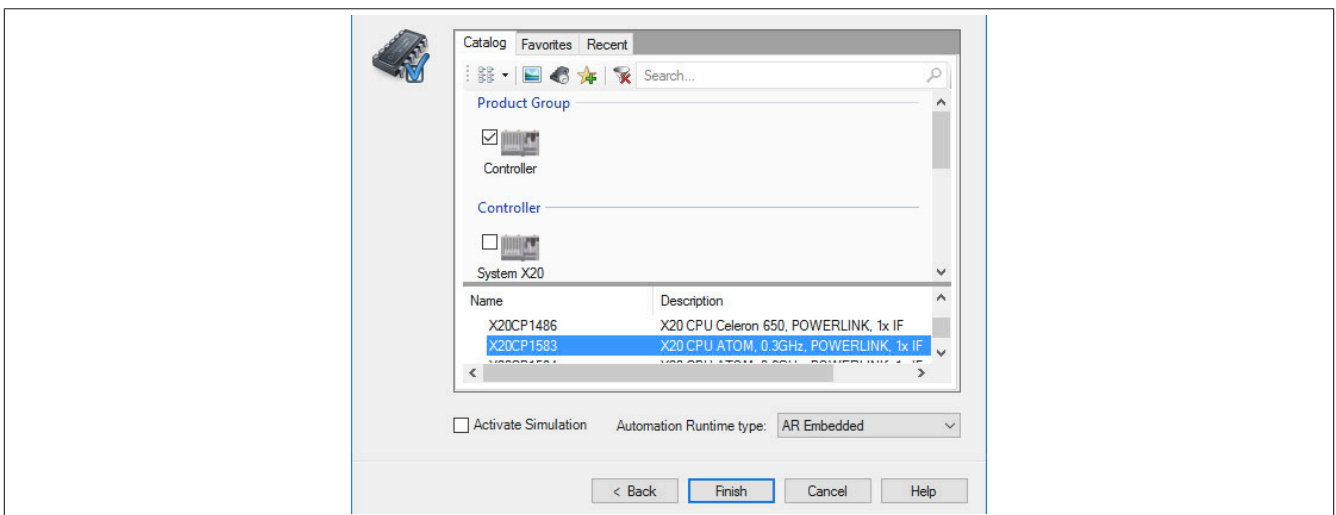

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

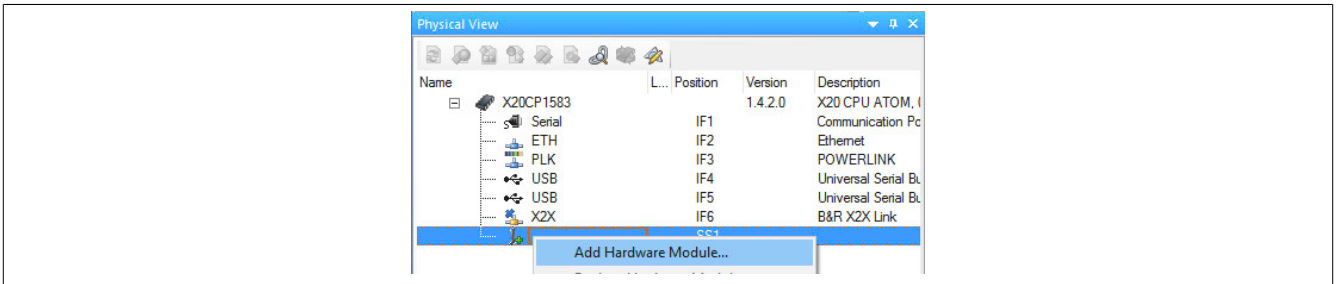

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

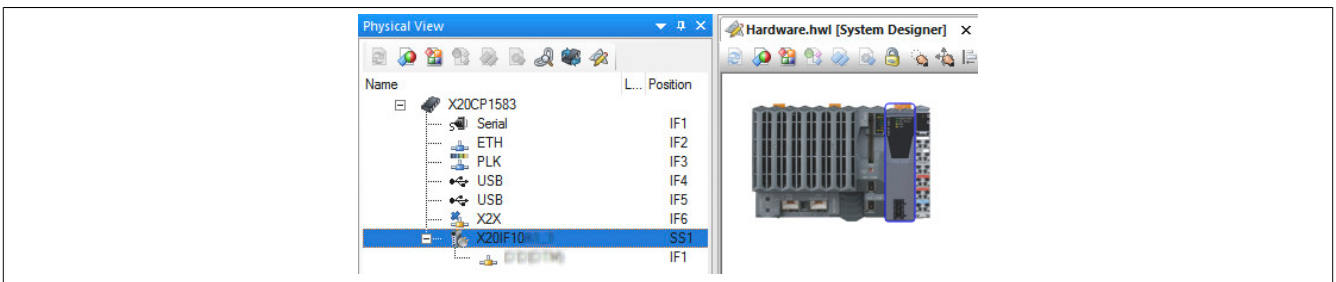

9.23.8.9.1.2 Adding and configuring the interface module

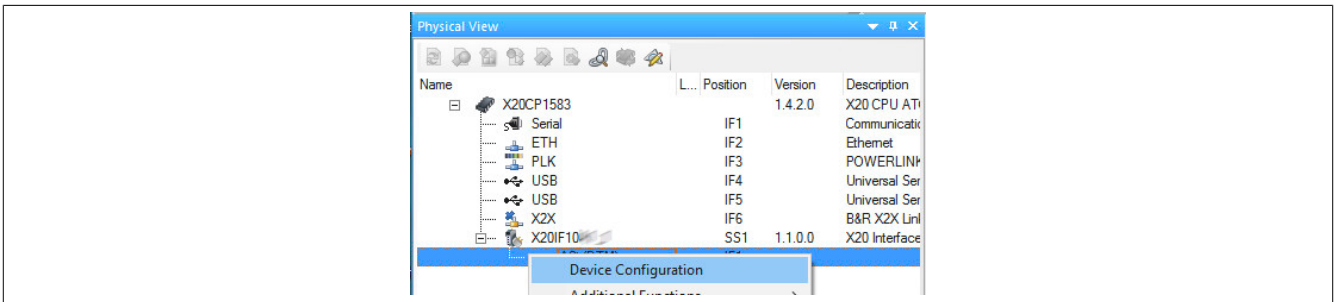

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

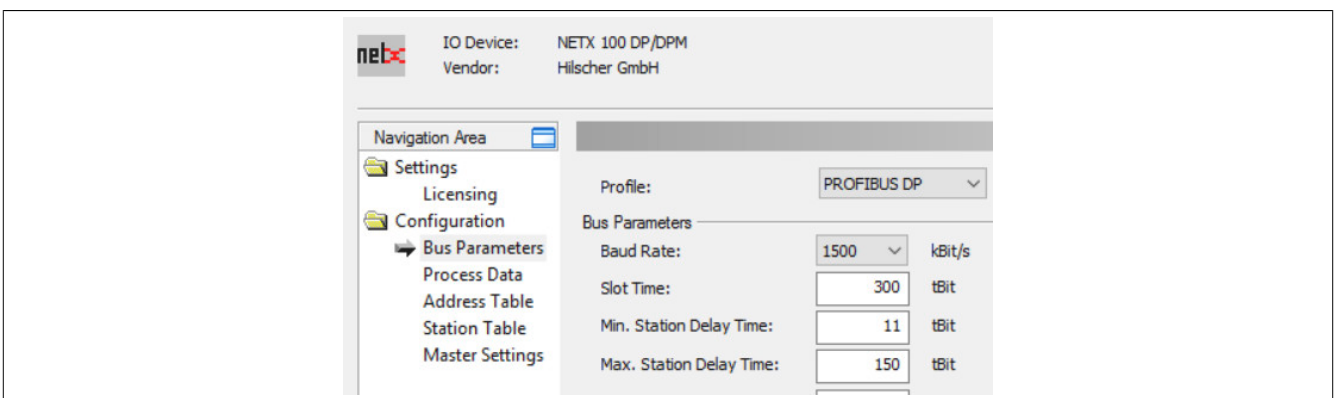

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

Bus parameters

- Profile

The desired PROFIBUS profile is set here.

| Parameter | Explanation |
|-------------|--|
| PROFIBUS DP | Decentralized peripherals: Used to control sensors and actuators and to connect several controllers with each other. |
| PROFIBUS PA | Process automation: Runs protocol-based via PROFIBUS DP V1 class 2 services just like PROFIBUS DP. PROFIBUS PA runs on a different physical layer, however. |

Both profiles can be connected using a media converter.

- Bus parameters

Depending on the profile used, the bus parameters must be set. When switching the profile, the default settings of the respective profile are automatically added.

| Parameter | Explanation | Values |
|-------------------------------|---|-----------------|
| Baud rate | This parameter must be set the same for all devices. Changing the baud rate results in an automatic recalculation of dependent parameters, such as "Slot time". | |
| Slot time | This parameter is the monitoring time of the telegram transmitter and is used for the acknowledgment of the recipient. | 37 to 16383 |
| Min. station delay time | This parameter (min T_{SDR}) is the shortest time that must elapse between receiving the last bit of the telegram and transmitting the first bit of the following one. | 1 to 65535 |
| Max. station delay time | This parameter (max T_{SDR}) is the longest time span that must elapse between receiving the last bit of the telegram and transmitting the first bit of the following one. If an unanswered telegram (e.g. broadcast) is received, the transmitter must wait for this time to elapse before transmitting a new telegram. | 1 to 65535 |
| Quiet time | This parameter (T_{QUI}) defines the time delay that occurs with modulators and repeaters for the change from transmit to receive. | 0 to 127 |
| Setup time | This parameter (T_{SET}) is the response time of the transmitter. It determines the minimum time between receiving a confirmation and transmitting a new poll telegram. | 0 to 255 |
| Station address | This parameter defines the station address of the master. | 0 to 125 |
| Target rotation time | This parameter (T_{TR}) is the nominal token cycle time in milliseconds. The time the master has for transmitting the telegrams to the slaves depends on the difference between normal and actual token cycle time. The default value depends on the number of slaves and how they have been configured. | 1 to $2^{24}-1$ |
| GAP actualization factor | This parameter (G) determines after how many token cycles an added station is included in the token ring. After time " $G * T_{TR}$ " has elapsed, the station searches for other stations who want to be included in the logical ring. | 0 to 255 |
| Max. retry limit | This parameter determines the maximum number of retries to search for a station. | 1 to 15 |
| Highest station address (HSA) | This parameter is the highest bus address up to which the master searches to pass on the token to another master. <div style="border-left: 2px solid black; padding-left: 5px; margin-left: 20px;"> The address must always be higher than the station address of the master </div> | 1 to 126 |

Settings for correct communication:

$$T_{QUI} < \min T_{SDR}$$

$$T_{RDY} < \min T_{SDR}$$

$$T_{QUI} < T_{RDY}$$

t_{BIT} (Bit time) is composed as follows:

$$t_{BIT} = 1 / \text{Baud rate (in bit/s)}$$

$$\text{Bit time} = \text{Time[ms]} * \text{baud rate}$$

- Bus monitoring

| Parameter | Explanation | Values |
|---|--|------------------|
| Data control time | This parameter defines the time in which Data_Transfer_List is updated at least once. After this time has elapsed, the master automatically reports its operating state via command "Global_Control". | 10 to 655,350 |
| Min. slave interval | This parameter defines the minimum time period between 2 slave list cycles. The maximum value required by the active stations is specified here. | 100 to 6,553,500 |
| Override slave-specific watchdog control time | Each slave transmits a specific watchdog control time back to the master. This parameter makes it possible to overwrite individual slave-specific settings with the same value for all slaves configured on this master, for example, to set a consistent value for slower transfer rates for critical environments. | |
| Watchdog control time | The DP slaves use the watchdog control time setting to detect communication errors on the assigned master. If the slave detects an interruption in an already operational communication defined by a watchdog time, the slave performs an independent reset and sets the outputs to the safe state. | |

Information:

If the bus configurations are changed and this change affects the bus parameters, a symbol (yellow exclamation mark) is displayed next to the affected parameters.

| Bus Monitoring | | | |
|----------------------|---|----------------------------------|--|
| Data Control Time: |  | <input type="text" value="20"/> | ms <input checked="" type="checkbox"/> Override slave specific Watchdog Control Time |
| Min. Slave Interval: | | <input type="text" value="200"/> | µs |
| | | Watchdog Control Time: | <input type="text" value="20"/> ms |

The bus parameters can be recalculated by clicking on "Adjust".

| | | |
|---|---|---------------------------------------|
|  | Values marked with this symbol should be adjusted to changes in the topology. | <input type="button" value="Adjust"/> |
|---|---|---------------------------------------|

Error handling

"Auto clear" ON is used for error handling.

| Parameter | Explanation |
|-----------|---|
| Enabled | The master changes from mode Operate to mode Clear (standby mode) and ends communication with all slaves as soon as at least one slave does not respond within the data control time. |
| Disabled | The master remains in mode Operate and communication with all accessible slaves is maintained. |

- Calculated timing

Calculated timing is the time the transmitter remains idle after receiving the last bit of a telegram on the bus until the first bit of a new telegram is transmitted on the bus.

| Bus time | Explanation | Formula |
|----------|---|--|
| Tid1 | Tid1 starts after the initiator has received an acknowledgment, response or token telegram. | $T_{id1} = \max(T_{QUI} + 2 * T_{SET} + 2 + T_{SYN}, \min T_{SDR})$ $T_{SYN} (*)$ |
| Tid2 | Tid2 starts after the initiator has transmitted a telegram that is not confirmed. | $T_{id2} = \max(T_{QUI} + 2 * T_{SET} + 2 + T_{SYN}, \max T_{SDR})$ $T_{SYN} (*)$ |

Process data

This table lists the process data of the individual slaves.

| Parameter | Explanation |
|-----------|---|
| Type | Device designation specified by the hardware. Further description of modules configured on the device or the input or output signals. |
| Tag | Name of the input or output data. |
| SCADA | This parameter is not supported. |

Address table

This table lists all slaves categorized according to their input and output data. The respective length of the input and output data as well as the assigned address can be read.

"Display mode" allows toggling between decimal and hexadecimal display.

| Parameter | Explanation |
|-----------------|---|
| Station address | Station address of the assigned slave device |
| Device | Actual device name of the slave assigned from the GSD file. |
| Name | Name of the assigned slave device |
| Modules | Name of the module per the GSD file |
| Type | Type of input or output data |
| Length | Number of data types contained |
| Address | Offset address of the input or output data |

The address table can also be exported as a CSV file.

If auto-addressing is disabled, addresses can be entered manually.

Information:

If addresses are assigned twice, an error is output and the addresses affected are marked with a red exclamation mark.

Station table

All slaves are listed in this table.

| Parameter | Explanation |
|-----------------|--|
| Activate | This allows the slaves to be enabled or disabled. <ul style="list-style-type: none"> • Slave disabled: The master reserves memory in the process data image for the slave, but no data is exchanged. • Slave enabled: The master reserves memory in the process data image for the slave, and data is exchanged. |
| Station address | Station address of the assigned slave device. This address can be changed. |

Master settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

- Module alignment

The addressing mode is defined by the process image here. The addresses (offsets) of the process data are always interpreted as byte addresses.

| Addressing mode | Explanation |
|-------------------|---|
| Byte boundaries | The module address can start on any offset. |
| 2 byte boundaries | The module address can only start on even byte offsets. |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|-----------------------------|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values | 20 to 65535 ms |
| | Default value: 1000 ms | |

Information:

The watchdog time is reset automatically by Automation Runtime.

- Process data handshake

This parameter configures the handshake for the data exchange between application and device. Only "Buffered, host-controlled" is supported here.

- Process image storage format

This is used to define how data is stored in the process image (I/O mapping). The storage format is only applied to data type "Word". This change has no effect on other data types.

| Storage format | Explanation |
|----------------|---|
| Big-endian | MSB/LSB = Higher/Lower byte (Motorola format) |
| Little-endian | MSB/LSB = Higher/Lower byte (Intel format) |

Input process image

Storage format - Little-endian (default setting)

| | | | | | | | | | |
|--------------------|---------|--------------------------|---------|-------|--------------------|---------|--------------------------|---------|-------|
| Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT | Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT |
| Module003_Input_2 | 16#3344 | <input type="checkbox"/> | 16#0000 | UINT | Module003_Input_2 | 16#4433 | <input type="checkbox"/> | 16#0000 | UINT |
| Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT | Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT |

Storage format - Big-endian

- Advanced

Information:

Function "Enable configuration download during network state operate" is not permitted to be enabled.

- Device status offset

Here, the status offset can be set to be calculated automatically or using a predefined value.

| Status offset | Explanation |
|-----------------------|--|
| Automatic calculation | The device status always directly follows the input bytes. If input data is added in the configuration, the start address of the device status is moved back in the dual-ported memory. |
| Static | <p>Here, the distance (free buffer) between the last input byte and the start of the device status can be set. This way, the start address of the device status never changes in the dual-ported memory. If additional input data is added, the distance (free buffer) is reduced. If the free buffer does not have enough space available for the data added to it, the start address of the device status in the dual-ported memory must be shifted.</p> <p>If the offset is too small, an error is output. To correct the error, the free buffer must be increased to a sufficient size.</p> |

Information:

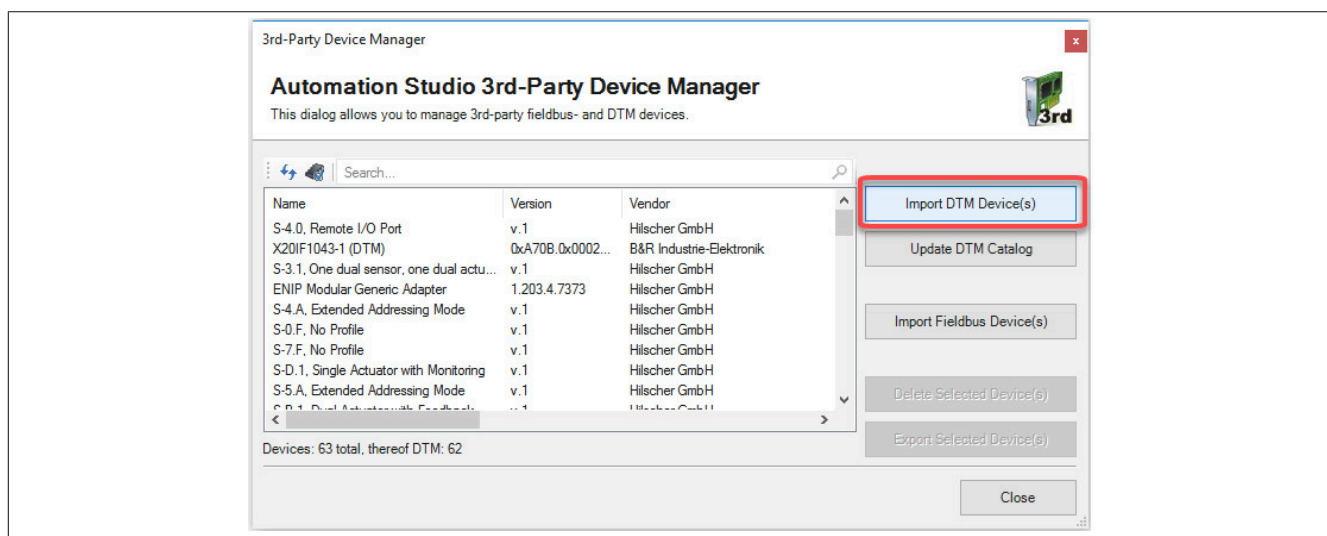

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

9.23.8.9.1.3 Adding the GSD file in Automation Studio

A device description file (GSD file) is required to inform the PROFIBUS DP master which slaves were connected and how they were configured.

To add and use a device description file in Automation Studio, perform the following steps:

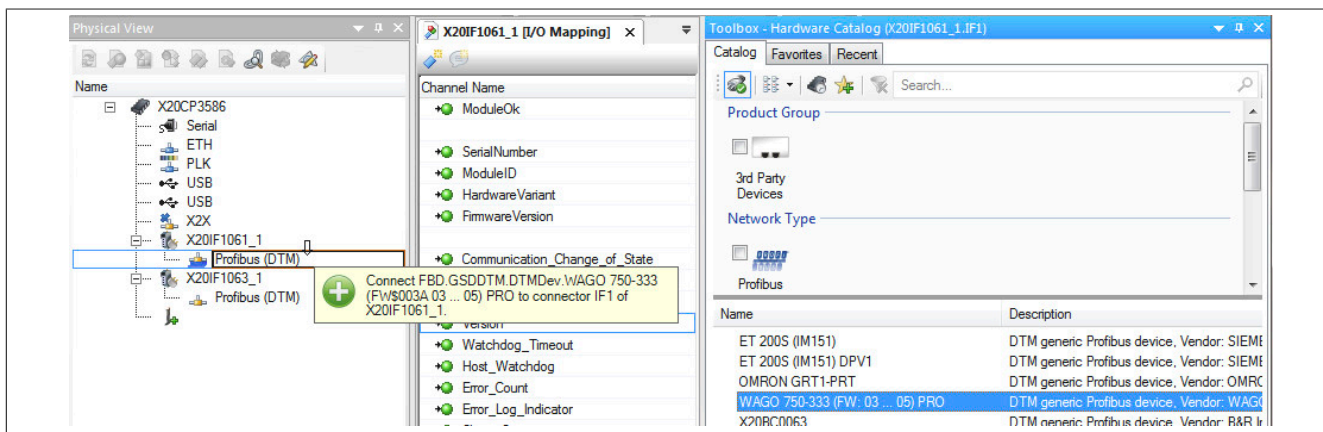

- If the PROFIBUS slave from B&R is used, download the GSD file from the B&R website (www.br-automation.com) and unzip the ZIP file.
- Open the dialog box in Automation Studio under "Tools - Manage 3rd-party devices" and select "Import DTM device(s)".

- Select the GSD file to be imported and confirm with OK. The GSD file is imported into Automation Studio.

- Click on "PROFIBUS (DTM)" on PROFIBUS DP master X20IF1061-1, drag the GSD file from the Hardware Catalog and attach it to the PROFIBUS DP master.

- Right-click on the IF interface and select "Device configuration" to open the configuration environment for the GSD file.

9.23.9 X20IF1063

Data sheet version: 2.23

9.23.9.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with a PROFIBUS DP V0 slave interface.

- PROFIBUS DP V0 slave connection

9.23.9.8 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.10 X20(c)IF1063-1

Data sheet version: 2.04

9.23.10.1 General information

The interface module is equipped with a PROFIBUS DP V1 interface. This allows the B&R system (I/O modules, POWERLINK, etc.) to be connected to systems from other manufacturers and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

- PROFIBUS DP V1 slave

9.23.10.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.10.2.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.23.10.3 Order data

| Model number | Short description | Figure |

- 2) Cable color: Green

9.23.10.6 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.10.6.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.10.6.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.10.7 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.10.8 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.10.9 Minimum DTM version for coated modules

Information:

The minimum DTM version required for coated modules is 1.0370.140220.12186. This version is included starting with Automation Studio upgrade packs V4.0.18.x and V3.0.90.29.

9.23.10.10 The PROFIBUS interface

Two steps are generally necessary for connecting module X20IF1063-1 to an external master environment.

- 1) Add and configure the X20 interface module in B&R's Automation Studio.
- 2) Add the PROFIBUS slave GSD device description file in the external master environment, e.g. Siemens STEP 7 or Siemens TIA-Portal. The interface module must then be configured.

Information:

To ensure error-free PROFIBUS communication between master and slave, the settings for the interface module in Automation Studio must match the settings of the GSD device description file in the master environment.

9.23.10.10.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

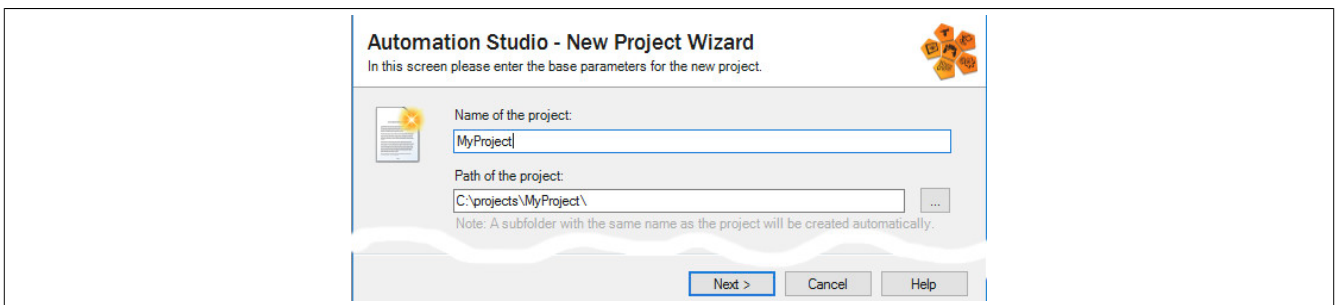

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.10.10.1.1 Creating an Automation Studio project

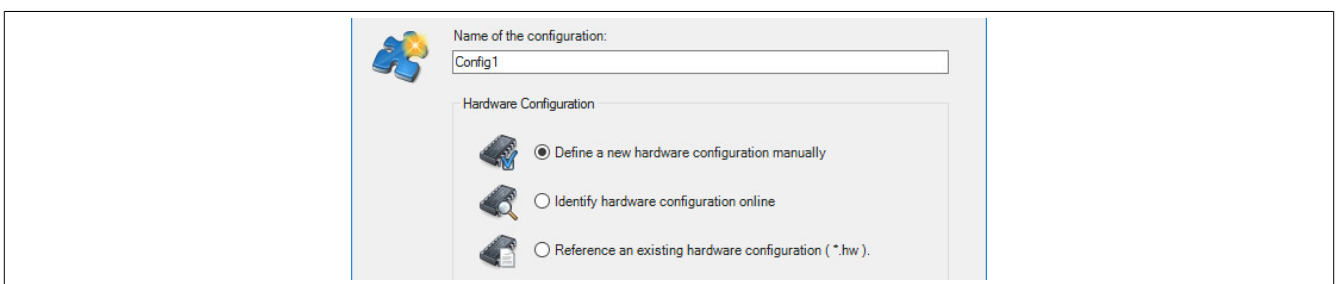

- Create a new Automation Studio project by selecting "New project".

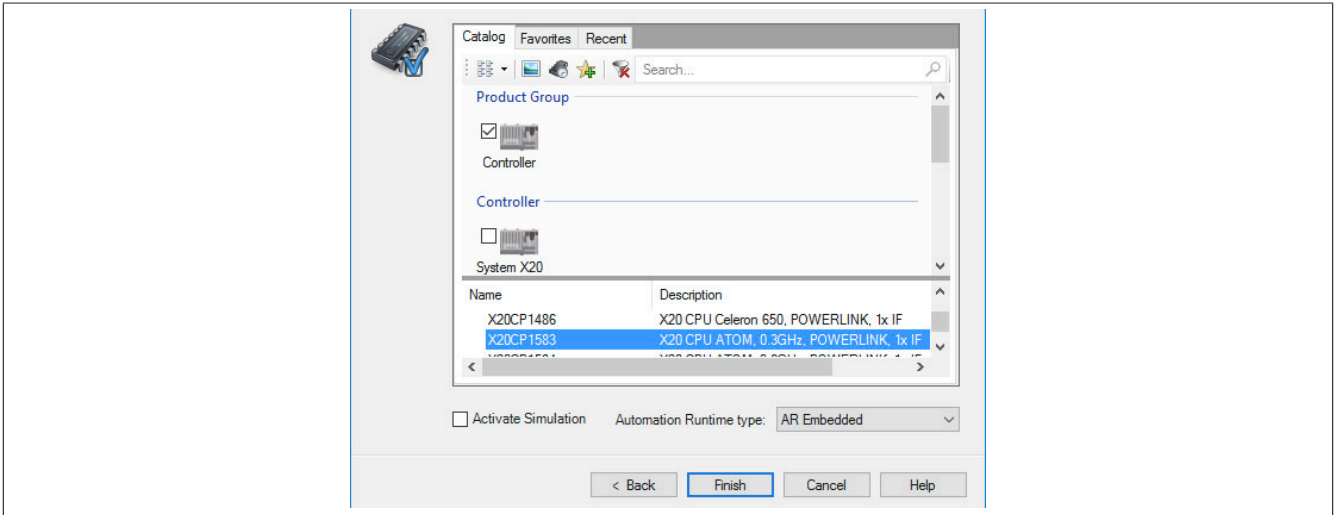

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

9.23.10.10.1.2 Adding and configuring the interface module

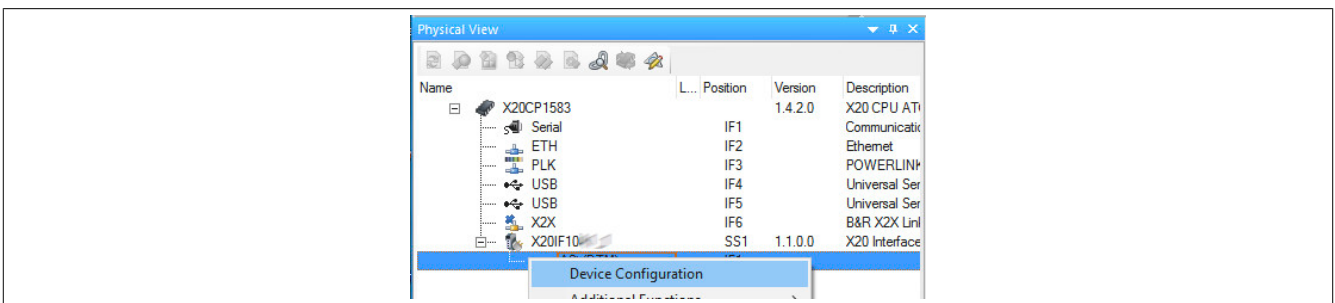

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

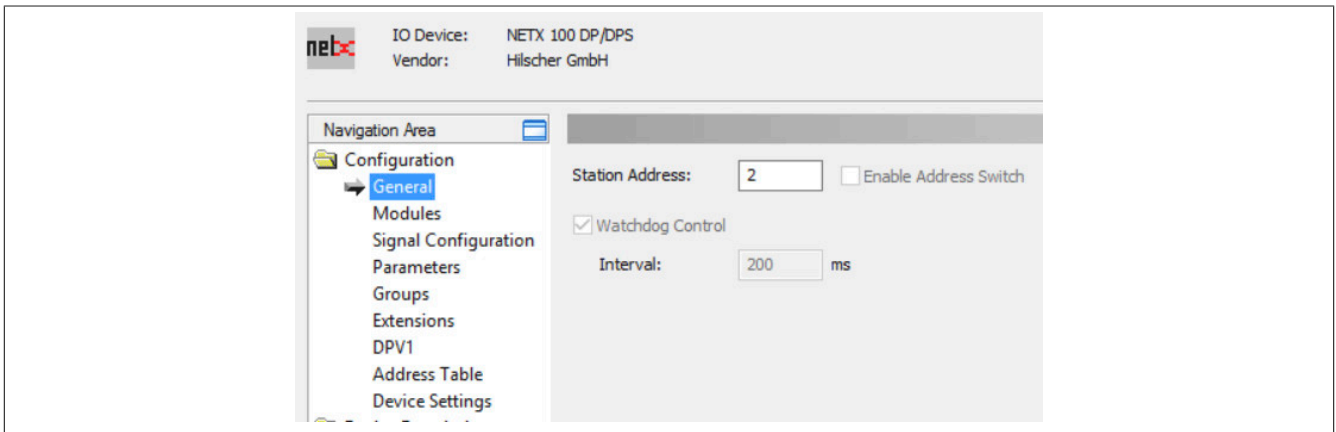

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

General

Only the station addresses can be set here. No other setting options are supported for this module.

| Parameter | Explanation | Values |
|-------------------------------|--------------------------------------|----------|
| Station address | The desired station address. | 0 to 125 |
| Enable address switch | This parameter is not supported. | |
| Watchdog control and interval | These parameters are only displayed. | |

Modules

- Available modules

All available modules are listed in this table. Modules can be added to the configuration using buttons **Insert** and **Append**.

- **Insert:** Adds a new module before the selected module.
- **Append:** Adds a new module at the end of the configured modules list.

- Configured modules

The configured modules are listed in this table. If necessary, these can be removed with button **Remove**.

Signal configuration

The data structure of the individual modules can be defined here; the name and data type of the inputs and outputs can also be adjusted. Data types can also be combined.

| Parameter | Explanation |
|-------------|--|
| Slot | Position of the slot |
| Name | Name of the slot |
| Module type | Number of bytes and type of connection (input or output) |

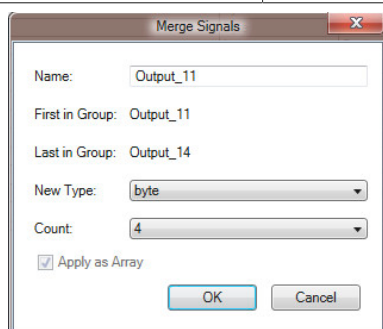

After selecting a slot, the type, data type and offset are displayed in another table below.

After right-clicking on the signal to be configured, the following options can be selected in the shortcut menu:

- **Edit signal**

This allows the currently selected signal to be edited.

| Parameter | Explanation |
|----------------|--|
| Name | The new name for the signal |
| New type | The new data type for the signal |
| Count | Number of individually listed data type elements for the signal. Only the data of the original type is re-structured; the quantity is not adjusted. - The maximum number corresponds to the quantity that the new data type requires to display the original type. - If fewer elements are selected, the last data type element is listed as an array of all remaining elements. |
| Apply as array | If selected, the new data type is displayed as an array. Otherwise, the data type elements set under "Count" are displayed. |

| Slot 5 12 Bytes Out | | |
|-----------------------|--------------|--------|
| Name | Type | Offset |
| Output_3 | byte | 3 |
| Output_4 | byte | 4 |
| Output_5 | byte | 5 |
| Output_6 | byte | 6 |
| Output_7 | byte | 7 |
| Output_8 | byte | 8 |
| Output_9 | byte | 9 |
| Output_10 | byte | 10 |
| Output_11 | 4 byte array | 11 |

- **Reset**

This can be used to undo the signal change or a merge previously completed with "Merge signal".

- **Merge signal**

This allows all signals between "First in group" and "Last in group" to be merged to form a new group. The same settings can be made for the new group as under "Edit signal".

The settings made are reflected in the process image (I/O mapping).

Configuring the signal

| Slot | Name | Type | Offset |
|--------|----------------------|-------|--------|
| Slot 1 | 8 Bytes In | | |
| | Temp_1 | byte | 0 |
| | Pressure_5 | byte | 1 |
| | Input_3_Byte_0_Bit_0 | bit | 2.0 |
| | Input_3_Byte_0_Bit_1 | bit | 2.1 |
| | Input_3_Byte_0_Bit_2 | bit | 2.2 |
| | Input_3_Byte_0_Bit_3 | bit | 2.3 |
| | Input_3_Byte_0_Bit_4 | bit | 2.4 |
| | Input_3_Byte_0_Bit_5 | bit | 2.5 |
| | Input_3_Byte_0_Bit_6 | bit | 2.6 |
| | Input_3_Byte_0_Bit_7 | bit | 2.7 |
| | Input_4 | byte | 3 |
| | Counter_Airflow_1 | dword | 4 |

Process image

| | | | | |
|--------------------------------|-------|--------------------------|-------|-------|
| Module001_Temp_1 | 0 | <input type="checkbox"/> | 0 | USINT |
| Module001_Pressure_5 | 0 | <input type="checkbox"/> | 0 | USINT |
| Module001_Input_3_Byte_0_Bit_0 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_1 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_2 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_3 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_4 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_5 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_6 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_7 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_4 | 0 | <input type="checkbox"/> | 0 | USINT |
| Module001_Counter_Airflow_1 | 0 | <input type="checkbox"/> | 0 | UDINT |

Parameters

These settings are not relevant because data types "Byte" and "Word" do not have parameter data.

Groups

These settings are configured in the GSD device description file on the PROFIBUS master. The master communicates the configuration to the slave via PROFIBUS.

The selected group memberships are transferred to the slave during startup. The group membership acts as a filter for global commands "Sync" and "Freeze". These are output as broadcast telegrams in order to synchronize the input and output data of the slaves. Only the slaves that have assigned to the group with the command respond to it.

| Parameter | Explanation |
|--------------------|------------------------------|
| Groups 1 through 8 | Selectable group memberships |

Extensions

These settings are configured in the GSD device description file on the PROFIBUS master. The master communicates the configuration to the slave via PROFIBUS.

- Auto clear

Function "Auto clear" is only used if "Auto clear on" has been enabled on the master.

| Parameter | Explanation |
|----------------------|---|
| Process "Auto clear" | In the event of a communication error, the master is put into standby mode and communication to the other slaves is aborted. |
| Ignore "Auto clear" | Communication errors to this slave are ignored. The master remains in mode "Operate" and communication to the other slaves is maintained. |

- Fail safe behavior

The "Fail safe" behavior shows the master whether the affected slave is working in mode "Fail safe".

| Parameter | Explanation |
|--|---|
| Slave receives zero data in Clear Mode | Mode "Fail safe" is enabled. In mode "Standby", the slave receives output data with a length of zero. |
| Slave receive no data in Clear Mode | Mode "Fail safe" is disabled. In mode "Standby", the slave does not receive output data. |

- Configuration data convention

Defines how configuration data is interpreted.

| Parameter | Explanation |
|-------------------|---|
| DPV1 compliant | Not supported by the module |
| EN50170 compliant | Configuration data interpreted per EN 50170 |

- Error on cyclic data exchange

Defines the behavior of the master in the event of error during cyclic data exchange.

| Parameter | Explanation |
|---|--|
| Continue if slave not responding. | The master remains in state DATA_EXCHANGE and retains the connection to the slave, even though the slave no longer responds and the master is not receiving any data from the slave. |
| Do not try to connect to slave on failure | The master does not remain in state DATA_EXCHANGE for the affected slave if the slave was detected as incorrect. |

- Diagnosis update delay

Some slaves require more time for the consistency check to process the SET_PRM configuration telegrams. In this case, the standard diagnostic cycle after the configuration phase is not sufficient for recognizing the arrangement of the slave for the DATA_EXCHANGE. "Diagnosis update delay" extends the number of diagnostic cycles after the configuration phase.

| Parameter | Explanation | Values |
|------------------------|--|----------|
| Diagnosis update delay | Specifies the delay time in cycles which the master waits before starting a new configuration phase. | 0 to 255 |

DPV1

These settings are configured in the GSD device description file on the PROFIBUS master. The master communicates the configuration to the slave via PROFIBUS.

Acyclic data exchange and alarm handling can be configured here.

| Parameter | Explanation | Values |
|--------------------------|---|----------|
| Enable DPV1 | Enables or disables the acyclic data exchange and alarm handling. | |
| Max. channel data length | Specifies the maximum length of the DPV1 alarm telegrams. The slave adapts its buffer size to the amount of data. | 4 to 244 |
| Max. alarm PDU length | Specifies the maximum number of active alarms | 4 to 64 |

- Alarm mode

This determines which alarms are transmitted by the slave.

| Parameter | Explanation |
|--|--|
| Alarm mode | Defines the maximum number of active alarms possible |
| Pull plug alarm Process alarm Diagnosis alarm Manufacturer specific alarm Status alarm Update alarm | Selection of alarms transmitted by the slave |

- Extra alarm SAP

This determines how the DPV1 master acknowledges an alarm from the DPV1 slave.

| Parameter | Explanation |
|------------------------------|--|
| Alarm acknowledge via SAP 51 | The PROFIBUS DPV1 master acknowledges alarms via SAP51 and uses SAP51 for DPV1 read/write. |
| Alarm acknowledge via SAP 50 | The PROFIBUS DPV1 master acknowledges alarms via SAP50. Nevertheless, the master still uses SAP51 for DPV1 read/write services. SAP50 is only used for acknowledging alarms and is not delayed by running DPV1 read-write services; this allows a higher performance to be achieved. |

Address table

This table provides information about the addresses of the input and output data (in decimal or hexadecimal notation).

"Display mode" allows toggling between decimal and hexadecimal display.

| Parameter | Explanation |
|-----------|--|
| Modules | Name of the module per the GSD file |
| Type | Type of input or output data |
| Length | Number of data types contained |
| Address | Offset address of the input or output data |

The address table can also be exported as a CSV file.

Device settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

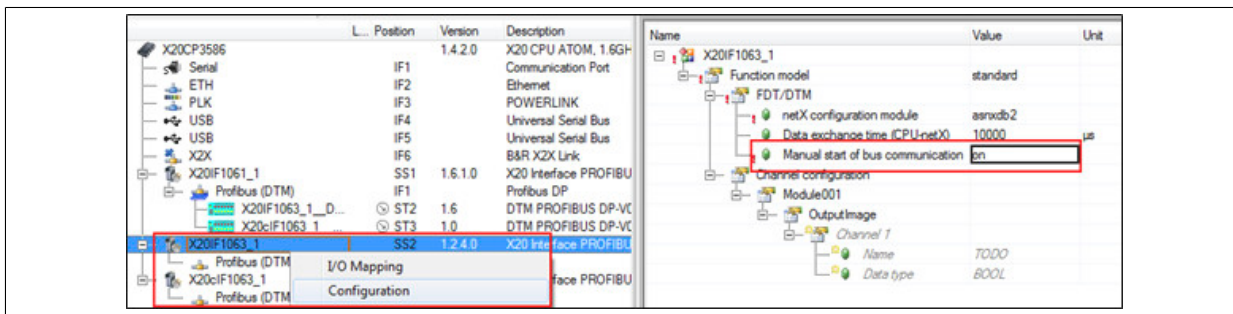

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

Information:

Parameter "Manual start of bus communication" can be enabled under the I/O configuration of the PROFIBUS slave.

The following settings must be made in order to avoid automatic data exchange:

- In the IF module configuration, "Manual start of bus communication" must be set to "On".

- "Start of bus communication" must be set to "Controlled by application".

With this setting, the communication can only be started via function block **AsNxDpS - nx dpsStartBusComm()**.

- Process image storage format

This is used to define how data is stored in the process image (I/O mapping). The storage format is only applied to data type "Word". This change has no effect on other data types.

| Storage format | Explanation |
|----------------|---|
| Big-endian | MSB/LSB = Higher/Lower byte (Motorola format) |
| Little-endian | MSB/LSB = Higher/Lower byte (Intel format) |

Storage format - Little-endian (default setting)

| | | | | | | | | | |
|--------------------|---------|--------------------------|---------|-------|--------------------|---------|--------------------------|---------|-------|
| Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT | Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT |
| Module003_Input_2 | 16#3344 | <input type="checkbox"/> | 16#0000 | UINT | Module003_Input_2 | 16#4433 | <input type="checkbox"/> | 16#0000 | UINT |
| Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT | Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT |

Storage format - Big-endian

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|-----------------------------|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values | 20 to 65535 ms |
| | Default value: 1000 ms | |

Information:

The watchdog time is reset automatically by Automation Runtime.

- Configuration data flag

The configuration used is defined here.

| Parameter | Explanation |
|---------------------------|--|
| Fixed configuration | Uses the configuration created in the slave DTM |
| Configuration from master | Not supported, i.e. no connection is established |

Device description

General device information and the entire GSD file can be read here.

9.23.10.10.2 GSD device description file

The module description is made available to the master in an GSD file. This text file contains the description of the slave's complete range of functions. The GSD file can be downloaded from the B&R website (www.br-automation.com) in the Downloads section for the interface module and then imported into the respective master environment.

9.23.11 X20(c)IF1072

Data sheet version: 2.34

9.23.11.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with a CAN bus interface.

- CAN bus connection
- Integrated terminating resistor

Information:

This module does not support CAN RTR messages with extended CAN identifiers (29-bit) (memory/performance bottleneck).

9.23.11.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.11.3 Order data

| Model number | Short description | Figure |

1) This CAN bus interface can be configured as a CANopen master in Automation Studio 3.0 and higher.

9.23.11.5 LED status indicators

| Figure | LED | Color | Status | Description |
|---|--------|--------|--------|---|
|  | STATUS | Green | On | Interface module active |
| | | Red | On | CPU starting up |
| | TxD | Yellow | On | The module is sending data via the CAN bus interface |
| | TERM | Yellow | On | Terminating resistor integrated in the module switched on |

9.23.11.6 Operating and connection elements

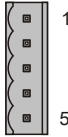

9.23.11.7 Node number switch

The node number for the interface is set with the two hex switches.

9.23.11.8 CAN bus interface

The interface is a 5-pin multipoint connector. Terminal block 0TB2105 must be ordered separately.

| Interface | | Pinout | |
|--|----------|------------------|------------|
|  5-pin male multipoint connector | Terminal | Function | |
| | 1 | CAN _⊥ | CAN ground |
| | 2 | CAN _L | CAN low |
| | 3 | SHLD | Shield |
| | 4 | CAN _H | CAN high |
| 5 | NC | | |

9.23.11.9 Terminating resistor

A terminating resistor is integrated in the interface module. It can be switched on or off with a switch on the bottom of the housing. A switched-on terminating resistor is indicated by LED "TERM".

9.23.11.10 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.12 X20IF1082

Data sheet version: 2.25

9.23.12.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an POWERLINK interface.

The interface has two RJ45 sockets. Both connections lead to an integrated hub. This makes it easy to create daisy-chain connections using POWERLINK.

- POWERLINK for real-time Ethernet communication
- Integrated hub for efficient cabling
- Configurable ring redundancy

9.23.12.2 Order data

| Model number | Short description | Figure |
|--------------|---|--|
| | X20 interface module communication | |

Table 442: X20IF1082 - Technical data

1) See Automation Help under "Communication / POWERLINK / General information / Hardware - IF/LS" for more information.

9.23.12.4 LED status indicators

| Figure | LED | Color | Status | Description |
|---|---------|-----------|----------|--|
|  | S/E | Green/Red | | Status/Error LED. The LED indicators are described in section "LED "S/E" (LED "Status/Error")" on page 2359. |
| | L/A IFx | Green | On | A link to the remote station has been established. |
| | | | Blinking | A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus |

9.23.12.4.1 LED "S/E" (LED "Status/Error")

This LED is a green/red dual LED and indicates the state of the POWERLINK interface. The LED states have a different meaning depending on the operating mode of the POWERLINK interface.

9.23.12.4.1.1 Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

| LED "S/E" | | Description |
|-----------|-----|---|
| Green | Red | |
| On | Off | The interface is operated as an Ethernet interface. |

Table: LED "S/E": Interface in Ethernet mode

9.23.12.4.1.2 POWERLINK V1 mode

| LED "S/E" | | Current state of the POWERLINK node |
|----------------------|----------|--|
| Green | Red | |
| On | Off | The POWERLINK node is running with no errors. |
| Off | On | A system error occurred. The type of error can be read using the PLC logbook. An irreparable problem has occurred. The system can no longer properly carry out its tasks. This state can only be changed by resetting the module. |
| Blinking alternately | | The POWERLINK managing node has failed. This error code can only occur when operated as a controlled node. This means that the set node number lies within the range 0x01 - 0xFD. |
| Off | Blinking | System stop. The red blinking LED indicates an error code (see "System stop error codes" on page 2361). |
| Off | Off | The interface is either not active or one of the following states or errors is present: <ul style="list-style-type: none"> The device is switched off. The device is in the startup phase. The interface or device is not configured correctly in Automation Studio. The interface or device is defective. |

Table 443: LED "S/E": POWERLINK V1 mode

9.23.12.4.1.3 POWERLINK V2 mode

Error message

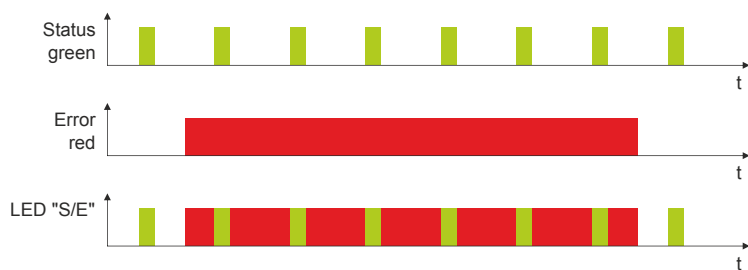

| LED "S/E" | | Description |
|-----------|-----|--|
| Green | Red | |
| Off | On | The interface is in error mode (failed Ethernet frames, increased number of collisions on the network, etc.). Note: Several red blinking signals are displayed immediately after the device is switched on. These are not errors, however. |
| Blinking | On | If an error occurs in the following modes, then the green LED blinks over the red LED: <ul style="list-style-type: none"> PRE_OPERATIONAL_1 PRE_OPERATIONAL_2 READY_TO_OPERATE  |

Table: LED "S/E" - Error message (interface in POWERLINK mode)

Interface status

| LED "S/E" | | Description |
|-----------------------------|-----|--|
| Green | Red | |
| Off | Off | <p>Mode: NOT_ACTIVE The interface is either in mode NOT_ACTIVE or one of the following modes or errors is present:</p> <ul style="list-style-type: none"> The device is switched off. The device is in the startup phase. The interface or device is not configured correctly in Automation Studio. The interface or device is defective. <p>Managing node (MN) The network is monitored for POWERLINK frames. If a frame is not received within the configured time window (timeout), the interface immediately enters mode PRE_OPERATIONAL_1. If POWERLINK communication is detected before the time has elapsed, however, the MN is not started.</p> <p>Controlled node (CN) The network is monitored for POWERLINK frames. If a frame is not received within the configured time window (timeout), the interface immediately enters mode BASIC_ETHERNET. If POWERLINK communication is detected before this time expires, however, the interface immediately enters mode PRE_OPERATIONAL_1.</p> |
| Flickering (approx. 10 Hz) | Off | <p>Mode: BASIC_ETHERNET The interface is in mode BASIC_ETHERNET. The interface is operated in <i>Ethernet mode</i>.</p> <p>Managing node (MN) This mode can only be exited by resetting the controller.</p> <p>Controlled node (CN) If POWERLINK communication is detected during this mode, the interface enters mode PRE_OPERATIONAL_1.</p> |
| Single flash (approx. 1 Hz) | Off | <p>Mode: PRE_OPERATIONAL_1 The interface is in mode PRE_OPERATIONAL_1.</p> <p>Managing node (MN) The MN is in "reduced cycle" operation. The CNs are configured in this mode. Cyclic communication is not yet taking place.</p> <p>Controlled node (CN) The CN can be configured by the MN in this mode. The CN waits until it receives an SoC frame and then switches to mode PRE_OPERATIONAL_2.</p> |
| | On | <p>Controlled node (CN) If the red LED lights up in this mode, this means that the MN has failed.</p> |
| Double flash (approx. 1 Hz) | Off | <p>Mode: PRE_OPERATIONAL_2 The interface is in mode PRE_OPERATIONAL_2.</p> <p>Managing node (MN) The MN starts cyclic communication (cyclic input data is not yet evaluated). The CNs are configured in this mode.</p> <p>Controlled node (CN) The CN can be configured by the MN in this mode. A command then switches the mode to READY_TO_OPERATE.</p> |
| | On | <p>Controlled node (CN) If the red LED lights up in this mode, this means that the MN has failed.</p> |
| Triple flash (approx. 1 Hz) | Off | <p>Mode: READY_TO_OPERATE The interface is in mode READY_TO_OPERATE.</p> <p>Managing node (MN) Cyclic and asynchronous communication. Received PDO data is ignored.</p> <p>Controlled node (CN) The configuration of the CN is completed. Normal cyclic and asynchronous communication. The transmitted PDO data corresponds to the PDO mapping. However, cyclic data is not yet evaluated.</p> |
| | On | <p>Controlled node (CN) If the red LED lights up in this mode, this means that the MN has failed.</p> |
| On | Off | <p>Mode: OPERATIONAL The interface is in mode OPERATIONAL. PDO mapping is active and cyclic data is evaluated.</p> |
| Blinking (approx. 2.5 Hz) | Off | <p>Mode: STOPPED The interface is in mode STOPPED.</p> <p>Managing node (MN) This mode does not occur for the MN.</p> <p>Controlled node (CN) Output data is not being output, and no input data is being provided. This mode can only be reached and exited by a corresponding command from the MN.</p> |

Table: LED "S/E" - Interface state (interface in POWERLINK mode)

Blink times

9.23.12.4.1.4 System stop error codes

A system stop error can occur due to incorrect configuration or defective hardware.

The error code is indicated by LED "S/E" blinking red. The blinking signal of the error code consists of 4 switch-on phases with short (150 ms) or long (600 ms) duration. The error code is repeated every 2 seconds.

| Error | Error description |
|----------------|---|
| RAM error | The device is defective and must be replaced. |
| Hardware error | The device or a system component is defective and must be replaced. |

9.23.12.5 Operating and connection elements

9.23.12.6 POWERLINK node number

The node number for the POWERLINK station is set using the two number switches. The node number can also be directly configured using Automation Studio.

9.23.12.6.1 POWERLINK V1

| Switch position | Description |
|-----------------|--|
| 0x00 | Operation as managing node. |
| 0x01 - 0xFD | Node number of the POWERLINK node. Operation as controlled node. |
| 0xFE - 0xFF | Reserved, switch position not permitted |

9.23.12.6.2 POWERLINK V2

| Switch position | Description |
|-----------------|---|
| 0x00 | Reserved, switch position not permitted. |
| 0x01 - 0xEF | Node number of the POWERLINK node. Operation as a controlled node (CN). |
| 0xF0 | Operation as a managing node (MN). |
| 0xF1 - 0xFF | Reserved, switch position not permitted. |

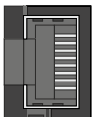

9.23.12.6.3 Ethernet mode

In this mode, the interface is operated as an Ethernet interface. The INA2000 station number is set using the B&R Automation Studio software.

9.23.12.7 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see ["Cabling guidelines for X20 modules with an Ethernet cable" on page 58](#).

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.23.12.8 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.13 X20(c)IF1082-2

Data sheet version: 1.25

9.23.13.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an POWERLINK interface.

The interface has two RJ45 sockets. Both connections lead to an integrated hub. This makes it easy to create daisy-chain connections using POWERLINK.

- POWERLINK for real-time Ethernet communication
- Integrated hub for efficient cabling
- Configurable ring redundancy
- Poll response chaining
- Dynamic Node Allocation (DNA)

9.23.13.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.13.5 LED status indicators

| Figure | LED | Color | Status | Description |
|---|-----------|-----------|----------|--|
|  | S/E | Green/Red | | Status/Error LED. The LED indicators are described in section "LED "S/E" (LED "Status/Error")" on page 2365. |
| | L/A X1/X2 | Green | On | A link to the remote station has been established. |
| | | | Blinking | A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus |

9.23.13.5.1 LED "S/E" (LED "Status/Error")

This LED is a green/red dual LED and indicates the state of the POWERLINK interface. The LED states have a different meaning depending on the operating mode of the POWERLINK interface.

9.23.13.5.1.1 Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

| LED "S/E" | | Description |
|-----------|-----|---|
| Green | Red | |
| On | Off | The interface is operated as an Ethernet interface. |

Table: LED "S/E": Interface in Ethernet mode

9.23.13.5.1.2 POWERLINK V1 mode

| LED "S/E" | | Current state of the POWERLINK node |
|----------------------|----------|--|
| Green | Red | |
| On | Off | The POWERLINK node is running with no errors. |
| Off | On | A system error occurred. The type of error can be read using the PLC logbook. An irreparable problem has occurred. The system can no longer properly carry out its tasks. This state can only be changed by resetting the module. |
| Blinking alternately | | The POWERLINK managing node has failed. This error code can only occur when operated as a controlled node. This means that the set node number lies within the range 0x01 - 0xFD. |
| Off | Blinking | System stop. The red blinking LED indicates an error code (see "System stop error codes" on page 2367). |
| Off | Off | The interface is either not active or one of the following states or errors is present: <ul style="list-style-type: none"> • The device is switched off. • The device is in the startup phase. • The interface or device is not configured correctly in Automation Studio. • The interface or device is defective. |

Table 446: LED "S/E": POWERLINK V1 mode

9.23.13.5.1.3 POWERLINK V2 mode

Error message

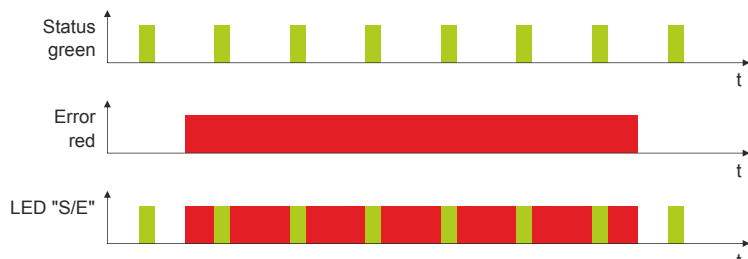

| LED "S/E" | | Description |
|-----------|-----|--|
| Green | Red | |
| Off | On | The interface is in error mode (failed Ethernet frames, increased number of collisions on the network, etc.). Note: Several red blinking signals are displayed immediately after the device is switched on. These are not errors, however. |
| Blinking | On | If an error occurs in the following modes, then the green LED blinks over the red LED: <ul style="list-style-type: none"> • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  |

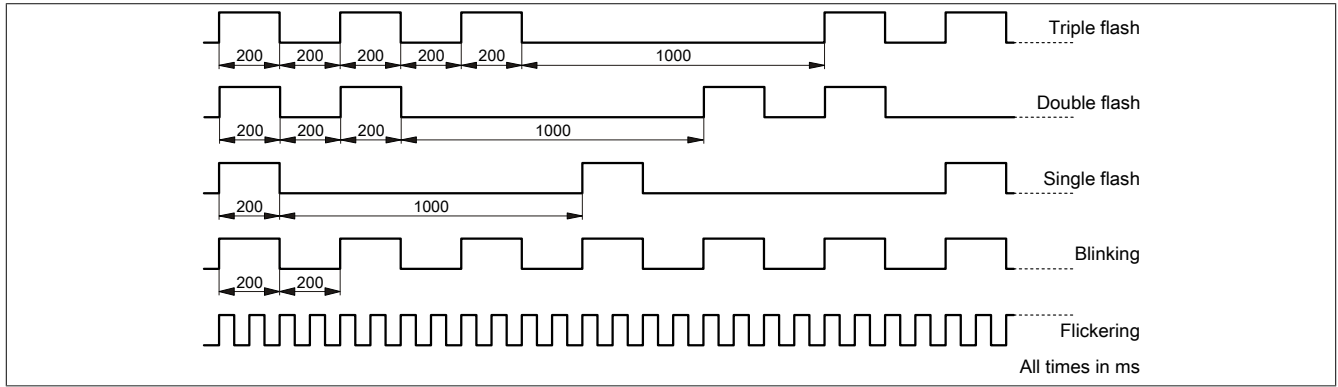

Table: LED "S/E" - Error message (interface in POWERLINK mode)

Interface status

| LED "S/E" | | Description |
|-----------------------------|-----|--|
| Green | Red | |
| Off | Off | <p>Mode: NOT_ACTIVE The interface is either in mode NOT_ACTIVE or one of the following modes or errors is present:</p> <ul style="list-style-type: none"> The device is switched off. The device is in the startup phase. The interface or device is not configured correctly in Automation Studio. The interface or device is defective. <p>Managing node (MN) The network is monitored for POWERLINK frames. If a frame is not received within the configured time window (timeout), the interface immediately enters mode PRE_OPERATIONAL_1. If POWERLINK communication is detected before the time has elapsed, however, the MN is not started.</p> <p>Controlled node (CN) The network is monitored for POWERLINK frames. If a frame is not received within the configured time window (timeout), the interface immediately enters mode BASIC_ETHERNET. If POWERLINK communication is detected before this time expires, however, the interface immediately enters mode PRE_OPERATIONAL_1.</p> |
| Flickering (approx. 10 Hz) | Off | <p>Mode: BASIC_ETHERNET The interface is in mode BASIC_ETHERNET. The interface is operated in <i>Ethernet mode</i>.</p> <p>Managing node (MN) This mode can only be exited by resetting the controller.</p> <p>Controlled node (CN) If POWERLINK communication is detected during this mode, the interface enters mode PRE_OPERATIONAL_1.</p> |
| Single flash (approx. 1 Hz) | Off | <p>Mode: PRE_OPERATIONAL_1 The interface is in mode PRE_OPERATIONAL_1.</p> <p>Managing node (MN) The MN is in "reduced cycle" operation. The CNs are configured in this mode. Cyclic communication is not yet taking place.</p> <p>Controlled node (CN) The CN can be configured by the MN in this mode. The CN waits until it receives an SoC frame and then switches to mode PRE_OPERATIONAL_2.</p> |
| | On | <p>Controlled node (CN) If the red LED lights up in this mode, this means that the MN has failed.</p> |
| Double flash (approx. 1 Hz) | Off | <p>Mode: PRE_OPERATIONAL_2 The interface is in mode PRE_OPERATIONAL_2.</p> <p>Managing node (MN) The MN starts cyclic communication (cyclic input data is not yet evaluated). The CNs are configured in this mode.</p> <p>Controlled node (CN) The CN can be configured by the MN in this mode. A command then switches the mode to READY_TO_OPERATE.</p> |
| | On | <p>Controlled node (CN) If the red LED lights up in this mode, this means that the MN has failed.</p> |
| Triple flash (approx. 1 Hz) | Off | <p>Mode: READY_TO_OPERATE The interface is in mode READY_TO_OPERATE.</p> <p>Managing node (MN) Cyclic and asynchronous communication. Received PDO data is ignored.</p> <p>Controlled node (CN) The configuration of the CN is completed. Normal cyclic and asynchronous communication. The transmitted PDO data corresponds to the PDO mapping. However, cyclic data is not yet evaluated.</p> |
| | On | <p>Controlled node (CN) If the red LED lights up in this mode, this means that the MN has failed.</p> |
| On | Off | <p>Mode: OPERATIONAL The interface is in mode OPERATIONAL. PDO mapping is active and cyclic data is evaluated.</p> |
| Blinking (approx. 2.5 Hz) | Off | <p>Mode: STOPPED The interface is in mode STOPPED.</p> <p>Managing node (MN) This mode does not occur for the MN.</p> <p>Controlled node (CN) Output data is not being output, and no input data is being provided. This mode can only be reached and exited by a corresponding command from the MN.</p> |

Table: LED "S/E" - Interface state (interface in POWERLINK mode)

Blink times

9.23.13.5.1.4 System stop error codes

A system stop error can occur due to incorrect configuration or defective hardware.

The error code is indicated by LED "S/E" blinking red. The blinking signal of the error code consists of 4 switch-on phases with short (150 ms) or long (600 ms) duration. The error code is repeated every 2 seconds.

| Error | Error description |
|----------------|---|
| RAM error | The device is defective and must be replaced. |
| Hardware error | The device or a system component is defective and must be replaced. |

9.23.13.6 Operating and connection elements

9.23.13.7 POWERLINK node number

The node number for the POWERLINK station is set using the two number switches. The node number can also be directly configured using Automation Studio.

9.23.13.7.1 POWERLINK V1

| Switch position | Description |
|-----------------|--|
| 0x00 | Operation as managing node. |
| 0x01 - 0xFD | Node number of the POWERLINK node. Operation as controlled node. |
| 0xFE - 0xFF | Reserved, switch position not permitted |

9.23.13.7.2 POWERLINK V2

| Switch position | Description |
|-----------------|---|
| 0x00 | Reserved, switch position not permitted. |
| 0x01 - 0xEF | Node number of the POWERLINK node. Operation as a controlled node (CN). |
| 0xF0 | Operation as a managing node (MN). |
| 0xF1 - 0xFF | Reserved, switch position not permitted. |

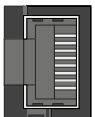

9.23.13.7.3 Ethernet mode

In this mode, the interface is operated as an Ethernet interface. The INA2000 station number is set using the B&R Automation Studio software.

9.23.13.8 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see ["Cabling guidelines for X20 modules with an Ethernet cable" on page 58](#).

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.23.13.9 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.14 X20IF1086-2

Data sheet version: 1.16

9.23.14.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an POWERLINK interface.

This interface uses a 100 Base-FX port. The POWERLINK connection is made using 62.5/125 μm or 50/125 μm fiber optic multimode cable with a duplex LC connection. The module and network status is indicated using LEDs.

- POWERLINK for real-time Ethernet communication
- 100 Base-FX port
- Poll response chaining
- Dynamic Node Allocation (DNA)

9.23.14.4.4.1 Wiring guidelines for X20 modules with fiber optic cable

The following wiring guidelines must be observed:

- Cable fiber type: Multimode fiber with 62.5/125 μm or 50/125 μm core diameter
- On both sides: Duplex LC male connector
- Observe minimum cable flex radius (see data sheet for the cable)

9.23.14.5 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.15 X20IF1091

Data sheet version: 2.23

9.23.15.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an X2X Link master interface.

- X2X Link connection

9.23.15.2 Order data

| Model number | Short description | Figure |

| | 2 | ASi+ |
| | 3 | ASi- |
| | 4 | ASi- |

9.23.16.5 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.16.5.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.16.5.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.16.6 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.16.7 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.16.8 The ASi interface

ASi stands for "Actuator Sensor Interface" and is a bus system for the lowest field level of automation technology. Using ASi bus systems provides an easy and affordable way to connect, operate and service sensors and actuators.

ASi is particularly suitable for safety-related components such as safety monitors, emergency stop switches or door locks.

The bus system is composed of a 2-conductor cable that transfers both power and information at the same time. This eliminates the need for parallel wiring, where each individual sensor or actuator is connected to the controller's input or output module via a separate wire.

ASi is a single master system, meaning only one master can be operated in a network at a time. The communication between master and slave works via the cyclic polling method. The master sends a poll request to each slave, which is answered by the individual slaves with a poll response.

Either 31 or 62 slaves can be operated depending on the type of addressing.

- Standard addressing is suitable for 1 to 32 slaves.
- Extended addressing is suitable for up to 62 slaves. Here, the slaves are grouped as A and B slaves, i.e. 1A to 31A and 1B to 31B).

Information:

Only ASi slaves with the ID code A can be addressed in extended form. With an ID code other than A, only the standard addressing of up to 32 slaves can be used.

9.23.16.8.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

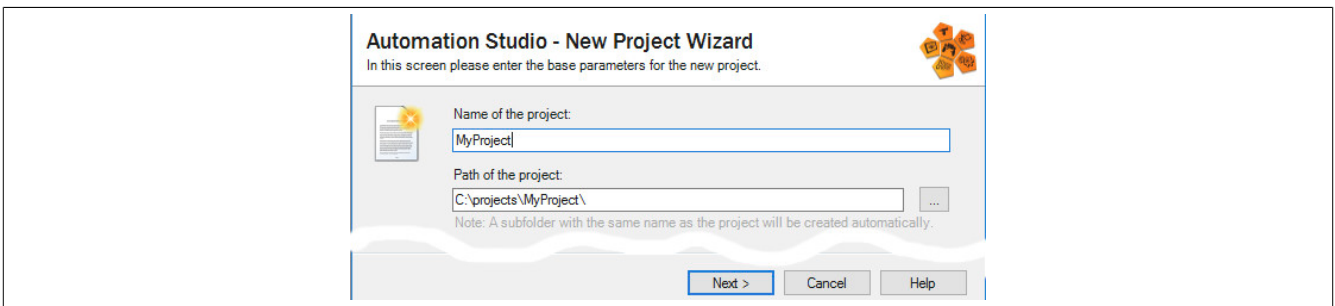

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.16.8.1.1 Creating an Automation Studio project

- Create a new Automation Studio project by selecting "New project".

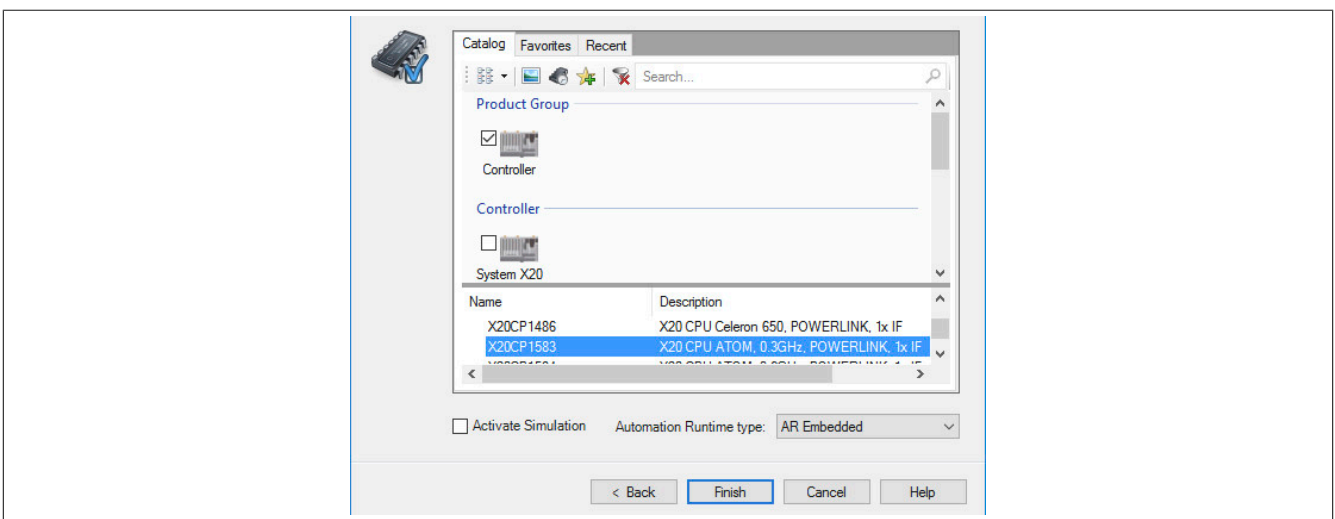

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

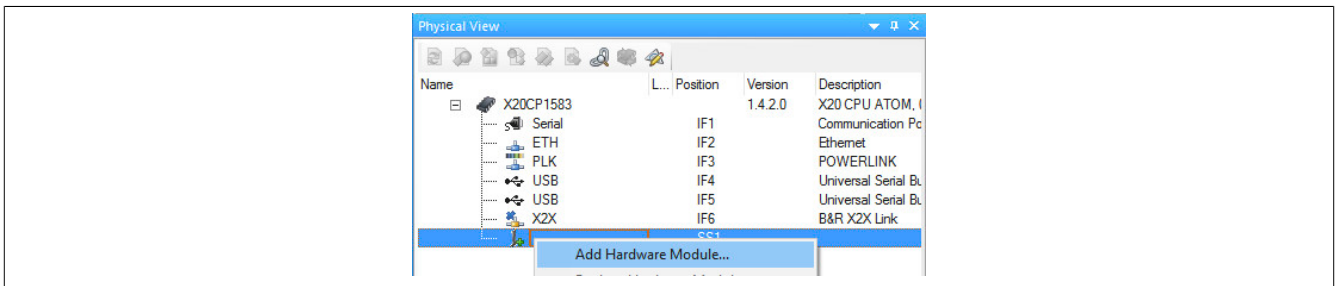

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

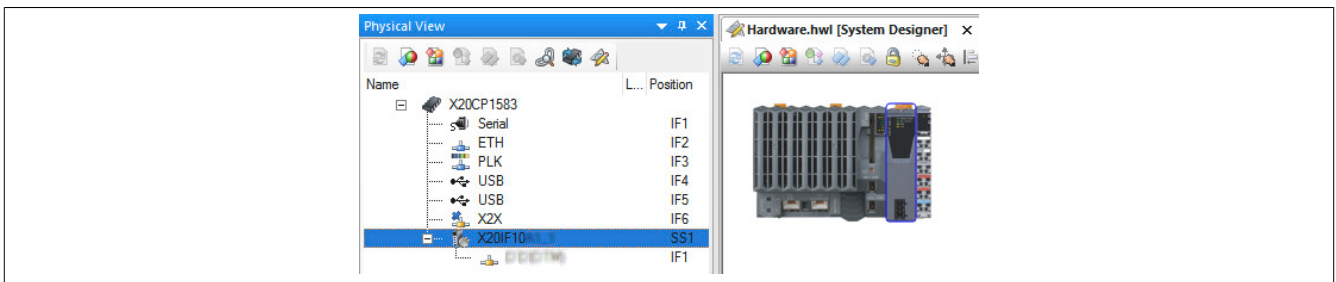

9.23.16.8.1.2 Adding an interface module

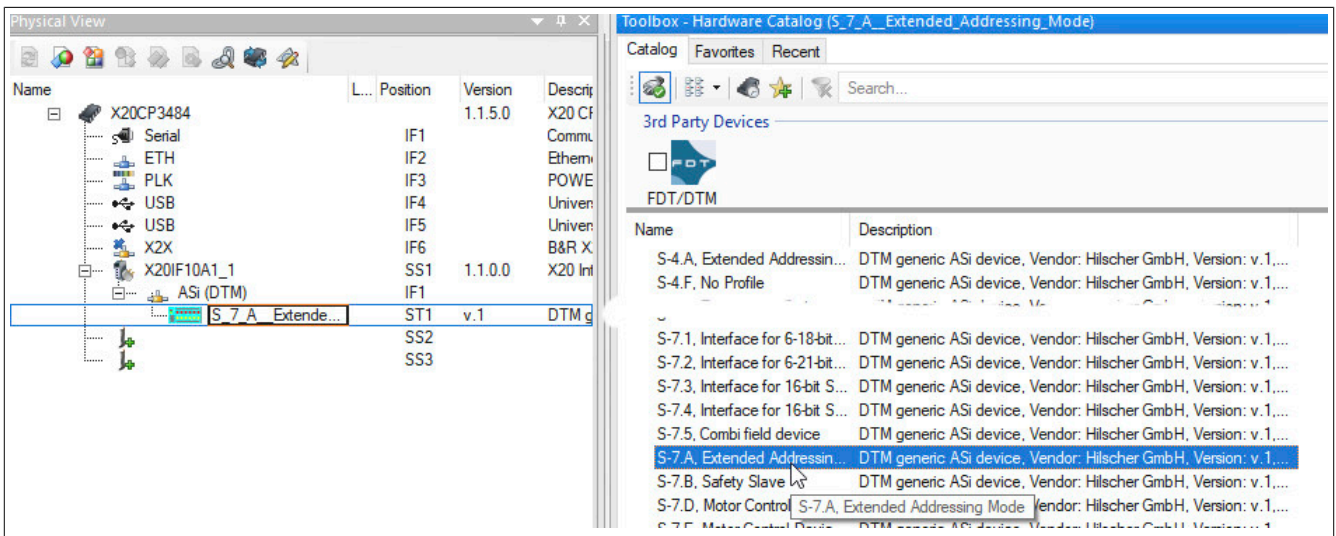

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- ASi slaves from the Hardware Catalog containing the required ASi profile can now be connected to the ASi master via drag-and-drop.

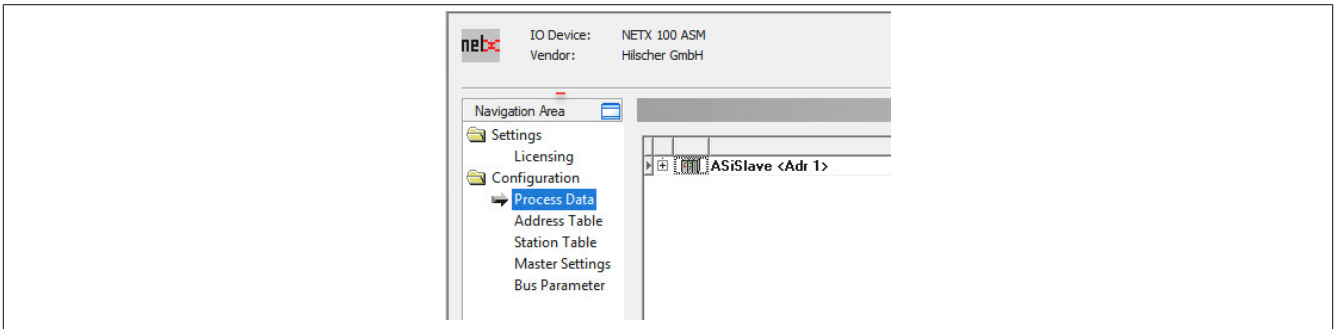

9.23.16.8.1.3 Configuring the ASi master

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

Process data

This table lists the process data of all attached slaves (device description files).

| Parameter | Explanation |
|-----------|---|
| Type | Device designation specified by the hardware. Further description of modules configured on the device or the input or output signals. |
| Tag | The name of the input and output data can be changed in column "Tag". |
| SCADA | This parameter is not supported. |

Address table

Contains a list of all slaves which are categorized according to their input and output data.

"Display mode" allows toggling between decimal and hexadecimal display.

| Parameter | Explanation |
|-----------------|---|
| Station address | Station address of the assigned slave device. |
| Device | Current device name of the assigned slave |
| Name | Device name of the assigned slave |
| Module | Name of the module |
| Type | Input or output type |
| Length | Number of bytes inserted (IB, QB, IW or QW). |
| Address | Input or output data offset address |

The address table can also be exported as a CSV file.

Station table

All ASi slaves are listed here.

| Parameter | Explanation |
|-----------------|---|
| Activate | This allows the slaves to be enabled or disabled. <ul style="list-style-type: none"> Enabled: Process memory is reserved and data is exchanged. Disabled: The master reserves memory in the process data image for the slave, but no data is exchanged. |
| Station address | Station address of the slave. Valid addresses: <ul style="list-style-type: none"> Standard address range: 1 to 31 Extended address range: 1A to 31A and 1B to 31B. In the application, this corresponds to the ranges 1 to 31 and 32 to 62. A/B slaves contain an "A" in their ID code. |
| Device | Name of the assigned slave |
| Name | Name of the assigned slave |
| Vendor | Vendor information |

Master settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

- Module alignment

The addressing mode is defined by the process image here. The addresses (offsets) of the process data are always interpreted as byte addresses.

| Addressing mode | Explanation |
|-------------------|---|
| Byte boundaries | The module address can start on any offset. |
| 2 byte boundaries | The module address can only start on even byte offsets. |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|-----------------------------|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values | 20 to 65535 ms |
| | Default value: 1000 ms | |

Information:

The watchdog time is reset automatically by Automation Runtime.

- Process image storage format

This is used to define how data is stored in the process image (I/O mapping). The storage format is only applied to data type "Word". This change has no effect on other data types.

| Storage format | Explanation |
|----------------|---|
| Big-endian | MSB/LSB = Higher/Lower byte (Motorola format) |
| Little-endian | MSB/LSB = Higher/Lower byte (Intel format) |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

- Process data handshake

This parameter configures the handshake for the data exchange between application and device. Only "Buffered, host-controlled" is supported here.

Bus parameters

— Behavior in case of defective slave device

The selection depends on the settings under "Behavior during startup sequence".

- **Don't take care about the status of any connected slave devices** - The slave status is disregarded but the communication remains intact.
- **Stop communication if a device is missing** - Communication is stopped if a slave is missing.
- **Stop communication if a device is reporting a periphery failure** - Communication is stopped if a slave reports a peripheral fault.
- **Stop communication if a device is missing or reporting a periphery failure** - Communication is stopped if a slave is missing or a peripheral fault is reported.

— Behavior during startup sequence

Determines the procedure of the master during startup in correlation with the connected slaves.

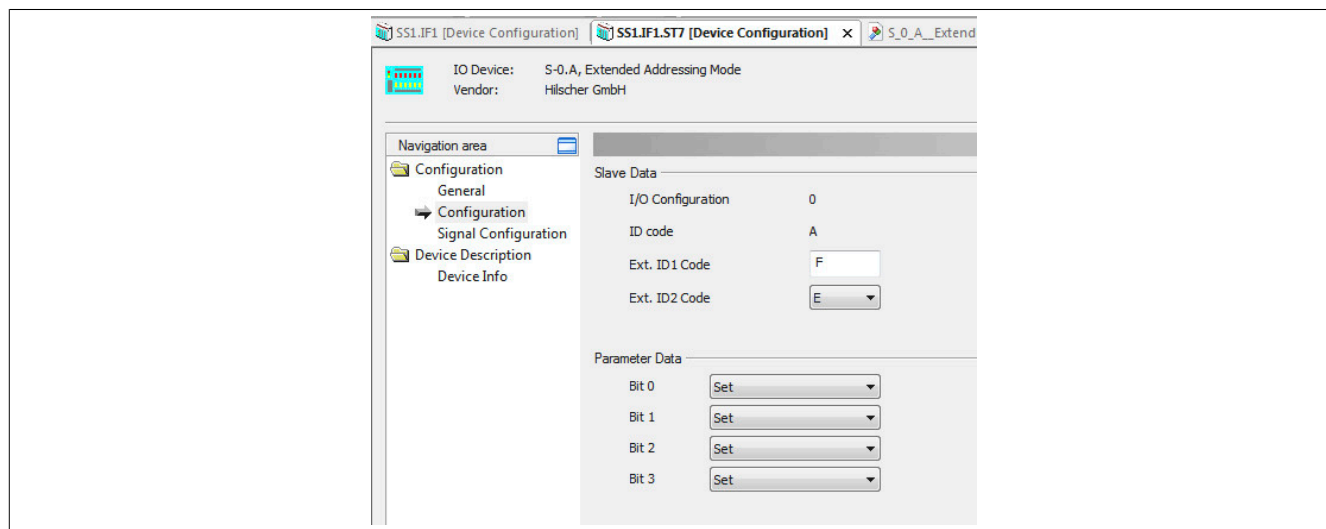

- **Protected mode** - If enabled, the master enters protected data exchange mode. If not enabled, the master enters configuration mode.
- **Auto address assignment** - If enabled, the master assigns a slave the address of a missing slave if it has an identical I/O, ID, ID1 and ID2 code and address 0.

— Overwrite configuration database

This parameter is not supported.

9.23.16.8.1.4 Configuring the ASi slave

- General settings can be made on the ASi slave using "Device configuration."

General

The description can be adjusted here. However, this is only used by the configuration dialog boxes and not by Automation Studio.

The slave address set on the master is also displayed. See "[Station table](#)" on page 2386 for setting the address.

Configuration

- Slave data

| Parameter | Explanation |
|-------------------|--|
| I/O configuration | I/O configuration used in the EDS file. This corresponds to the first position of the slave profile. |
| ID code | I/O code used in the EDS file. This corresponds to the second position of the slave profile. |
| Ext. ID1 code | Extended ID code, user-specific |
| Ext. ID2 code | Extended ID code, user-specific |

- Parameter data

| Parameter | Explanation | Values |
|----------------|---|--------------|
| Bit 0 to bit 3 | Parameter data to be set by the user. If these are contained in the EDS file, they are displayed here. | Set Reset |

Signal configuration

The name and data type of the I/O data point can be adjusted here.

The signal configuration can be set to the default values for the specified slave profile by clicking on "Default".

| Parameter | Explanation |
|-----------|--|
| Modules | Input or output modules of the signal configuration |
| Tag | Editable name of the individual input or output signals. The name can also be changed via the master (see " Process data " on page 2385) |
| Data type | Editable data type of the individual input or output signals. The data type can be selected from a list according to the AS slave profile defined in the EDS file. |
| Type | Type of input or output signal |

Device description

General device information can be read here.

9.23.16.8.2 EDS device description file

All possible ASi slave variants have already been imported into Automation Studio as device description files and can be taken from the Hardware Catalog.

Each ASi slave is assigned an ASi profile. The ASi profile is composed of 4 components:

- **I/O configuration**
Contains information about the configuration of individual ASi slave ports: output, input or bidirectional input/output.
- **ID code**
Contains the ID code of the slave.
- **Extended ID code 1**
Length: 4 bits
In extended address mode, the MSB indicates whether it is an A (MSB = 0) or B (MSB = 1) slave (starting with specification 3.0). In the Automation Studio Hardware Catalog, the extended address mode can be identified by an "A" in the slave address (e. g. "S-0. A"). The lower 3 bits contain additional slave-specific information.
- **Extended ID code 2**
Used for slave-specific settings. See description of the corresponding slave.

9.23.16.8.3 Slave addressing

There are 3 ways to assign an address to an ASi slave.

- With the programming device

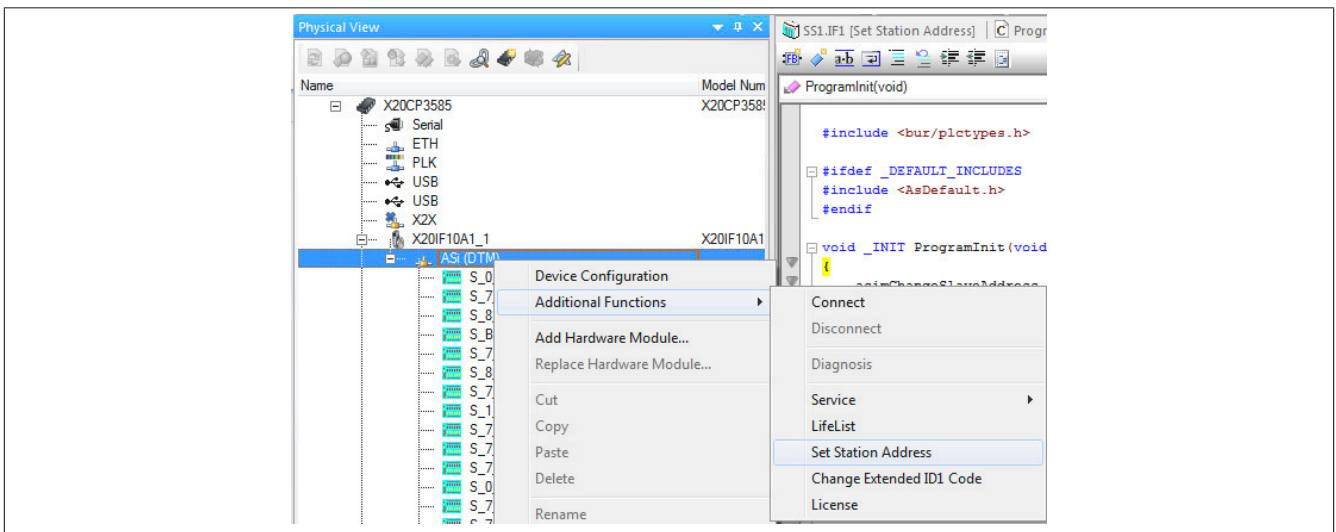

A programming interface is required for this, which does not exist for every slave. If a programming interface is installed in the ASi slave, the slave address can be adjusted via the programming device and the ASi profile can also be read.

- Assignment via function block

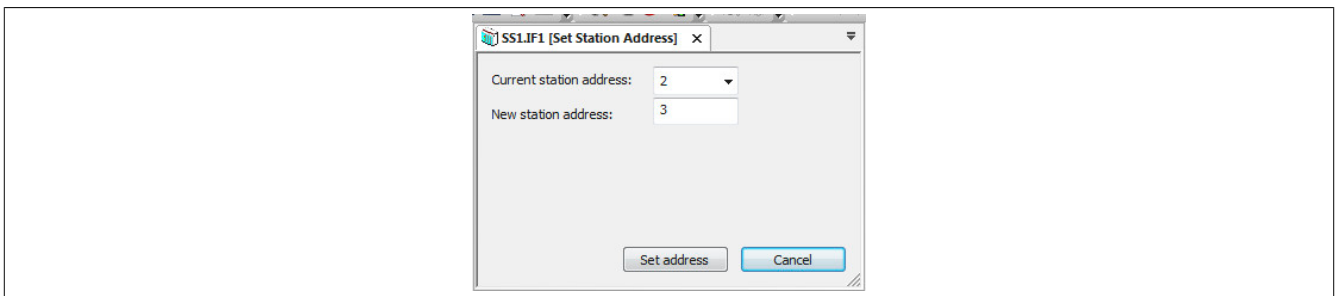

To do this, a program must be created and function block **AsNxAsiM - asimChangeSlaveAddress()** must be programmed. In order to change the slave address using this function block, the current address must be known. In most cases, address 0 (delivery state) is applied to a new ASi slave since no slave is permitted to have address 0.

- Direct mapping via the master

The current slave address is also required here. In the Physical View (Automation Studio), the slave address can be adjusted with a right-click on the ASi interface of the master → Additional functions → Set station address.

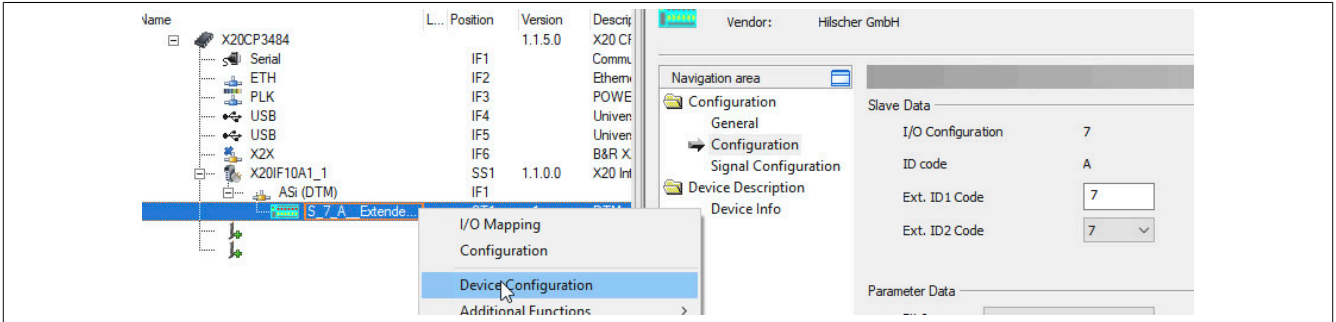

First, the slave to be addressed is selected and the desired new address is specified. A new address can be assigned using "Set address".

9.23.16.8.4 Configuration example

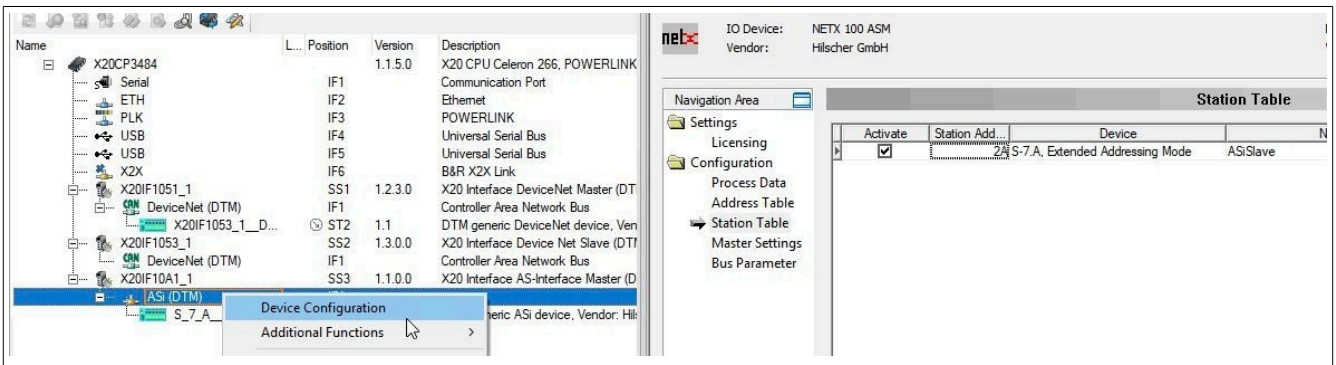

In this example, an ASi slave with the profile S-7.A is configured.

- The desired profile is first selected from the Hardware Catalog and added to the ASi master. See ["Adding an interface module" on page 2384](#).
- The ID code settings of the connected device are specified by the ASi slave manufacturer and must be set in the profile. The values under "Ext. ID1 code" and "Ext. ID2 code" are therefore entered via the device configuration of the device description file.

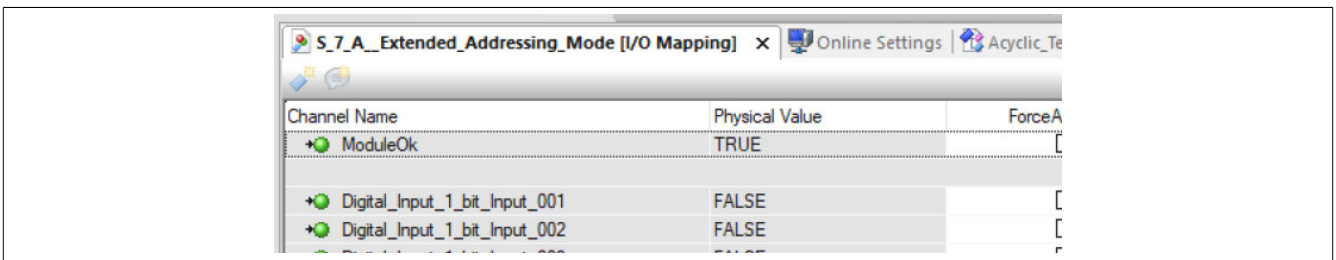

- The address of the ASi slave is then set in the device configuration on the master under "Station table".

Setting the address on the device itself is done differently depending on the ASi slave used, e.g. by a programming device, via a function block or via the master. See ["Slave addressing" on page 2389](#).

- Confirm and save all settings with OK. The configuration is transferred to the CPU and, if correct, a connection between master and slave is automatically established.

The connection status can be checked with the ModulOK bit in the I/O mapping of the device description file. When ModulOK = True, data can be exchanged between master and slave.

9.23.17 X20(c)IF10D1-1

Data sheet version: 3.04

9.23.17.1 General information

The interface module is equipped with an EtherNet/IP scanner interface. This allows third-party components to be integrated in the B&R system and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

The interface is equipped with 2 RJ45 connections. Both connections result in an integrated switch. This makes it easy to implement daisy chain cabling.

- EtherNet/IP scanner (master)
- Integrated switch for efficient wiring

9.23.17.1.1 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.17.1.1.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.23.17.2 Order data

| Model number | Short description | Figure |

9.23.17.4 Operating and connection elements

9.23.17.4.1 LED status indicators

| Figure | LED | Color | Status | Description |
|----------|--------------------------|------------|--|--|
| | READY/RUN | Green/Red | Off | No power to module |
| | | Green | On | PCI bus communication in progress |
| | | Red | Blinking | Boot error |
| | Mod status ¹⁾ | Green | Blinking | Communication on the PCI bus has not yet been started. |
| | | | On | The interface module has not yet been configured. |
| | | Red | Blinking | Scanner (master) is ready for operation. |
| | | | On | Correctable hardware errors |
| | Net status ¹⁾ | Green/Red | Blinking | Uncorrectable hardware errors |
| | | | On | Initialization/Self-test |
| | | Green | Off | No power to module |
| | | | Blinking | No active connections available |
| | | | On | A least one established active connection available |
| | L/A IF1/IF2 | Red | Blinking | A timeout occurred on at least one connection. |
| | | | On | An IP address has been used more than once. |
| | | Green/Red | Off | No IP address assigned or module not supplied |
| Blinking | | | Initialization/Self-test | |
| | Green | Off | No link to remote station | |
| | | Flickering | The link to the remote station is established. The LED blinks if Ethernet activity is taking place on the bus. | |
| | | On | The link to the remote station is established. | |

1) This LED is a green/red dual LED.

9.23.17.4.2 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see ["Cabling guidelines for X20 modules with an Ethernet cable"](#) on page 58.

| Interface | Pinout | | |
|----------------------|--------|-------------|----------------|
| | Pin | Ethernet | |
| <p>Shielded RJ45</p> | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.23.17.5 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.17.5.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.17.5.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.17.6 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.17.7 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.17.8 The EtherNet/IP interface

9.23.17.8.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

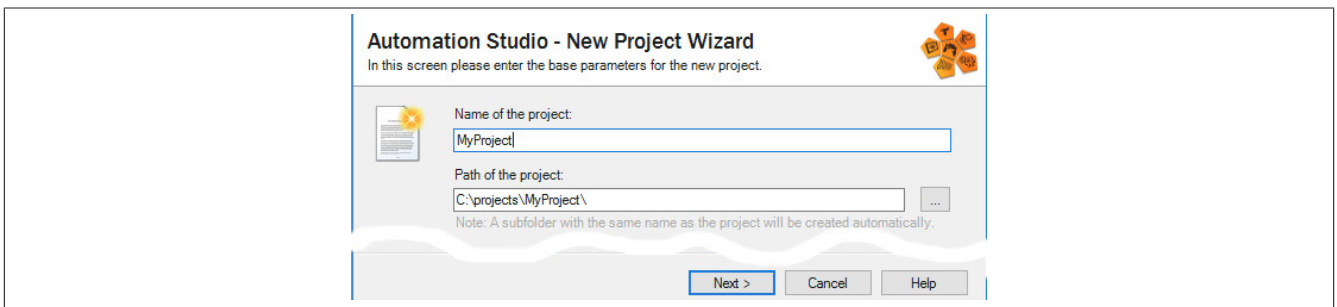

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.17.8.1.1 Creating an Automation Studio project

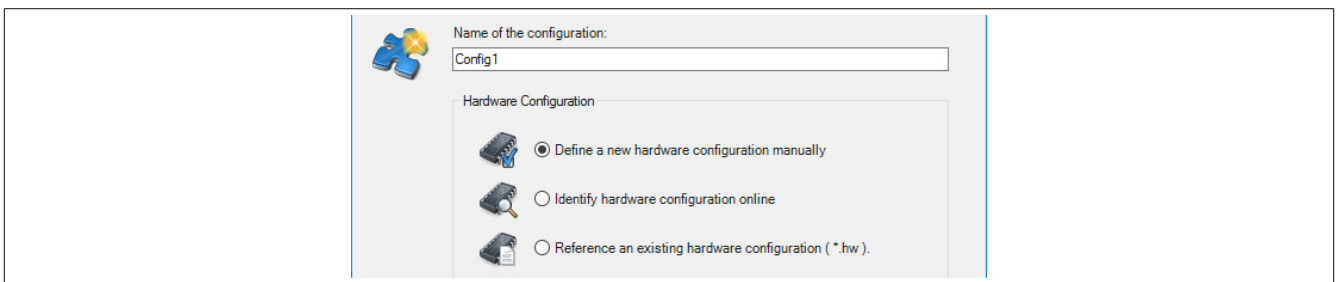

- Create a new Automation Studio project by selecting "New project".

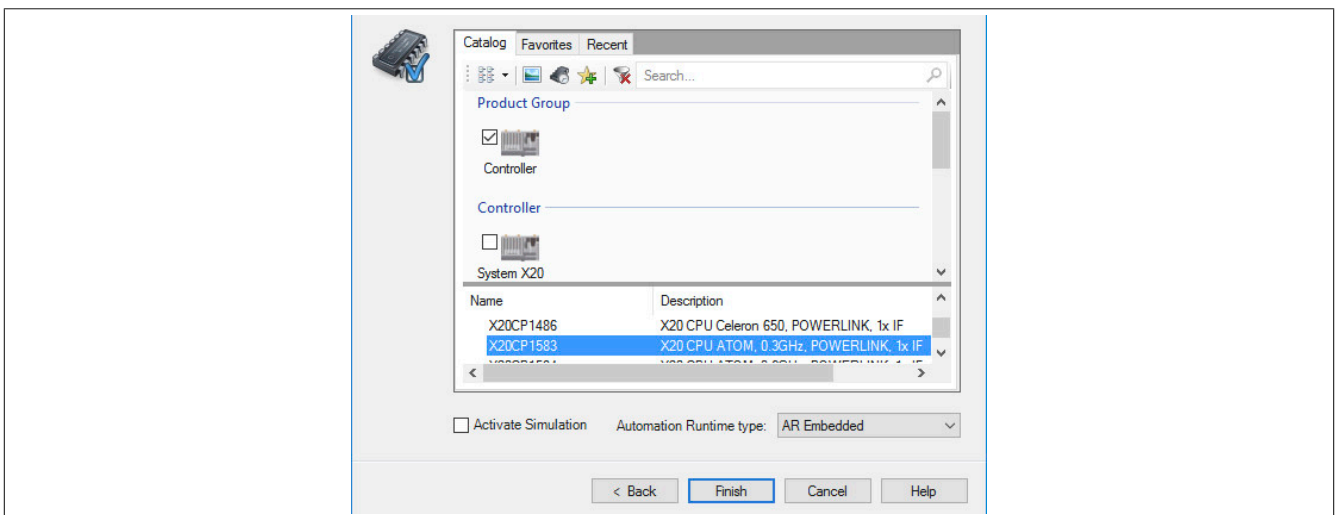

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

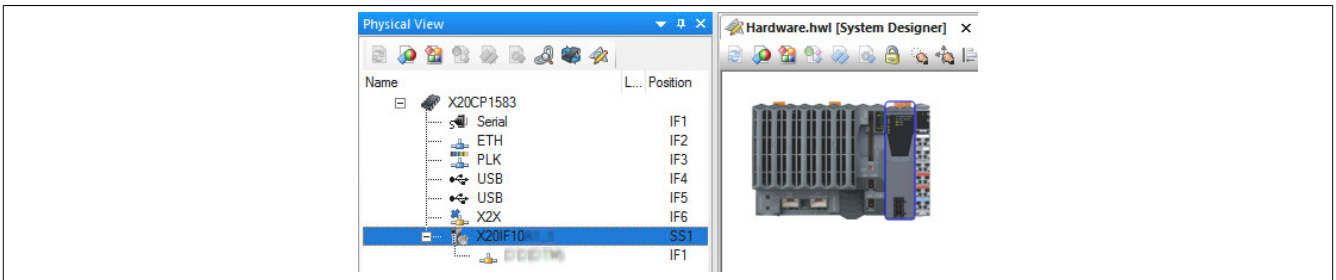

9.23.17.8.1.2 Adding and configuring the interface module

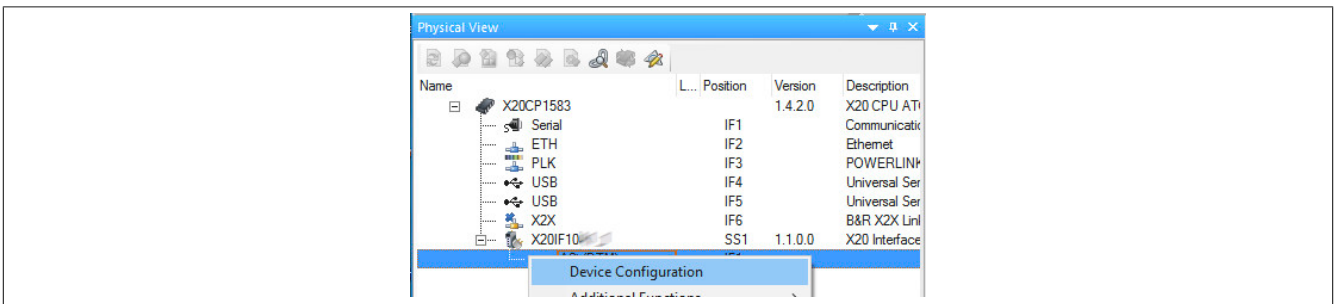

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

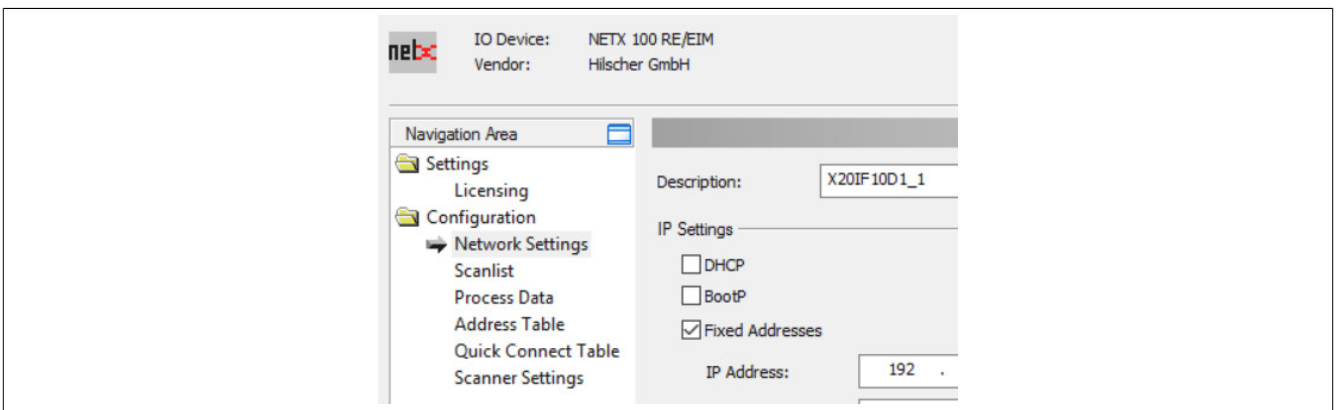

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

Network settings

Contains the symbolic name of the module

| Parameter | Explanation |
|-------------|----------------------------|
| Description | Module name of the scanner |

- IP settings

The IP addresses and operation modes of the Ethernet interface are set here.

| Parameter | Explanation |
|-----------------|--|
| DHCP | IP address determined via DHCP protocol. |
| BootP | IP address determined via BootP protocol. |
| Fixed addresses | The IP address is static. The IP address is defined by the following 3 parameters. |
| IP address | IP address of the EtherNet/IP scanner station |
| Network mask | Network mask of the EtherNet/IP scanner station |
| Gateway address | Gateway address of the EtherNet/IP scanner station |

- Port 1

| Parameter | Explanation |
|----------------|--|
| Operating mode | Operating mode of the EtherNet/IP scanner (master) |
| MDI mode | Configure cable type <ul style="list-style-type: none"> • Auto MDI-X: Detect cable type automatically • MDI-X: Use crossover cable. • MDI: Use straight-through cable. |

- Port 2

Identical to port 1

Scan list

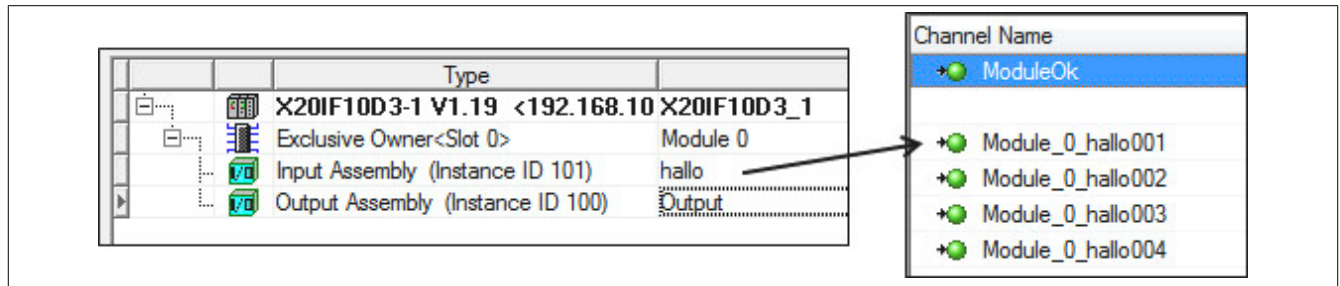

This table lists all attached EtherNet/IP adapters (slaves).

| Parameter | Explanation | Values | | | | | | | | | | | | | | | | | | | | |
|--------------------|---|---|-------|------------|---|-----|---|-----|---|------|---|----------------|---|------|---|-------|---|-------|---|-------|----------|----------|
| Activate | This is used to enable or disable the adapters. <ul style="list-style-type: none"> • Enabled: Process memory is reserved and data is exchanged. • Disabled: The master reserves memory in the process data image for the adapter, but no data is exchanged. | | | | | | | | | | | | | | | | | | | | | |
| Index | Continuous numbering of the EtherNet/IP devices in the scan list. | | | | | | | | | | | | | | | | | | | | | |
| IP address | Configurable IP address of the EtherNet/IP adapter station. | | | | | | | | | | | | | | | | | | | | | |
| Name | Editable station name. | | | | | | | | | | | | | | | | | | | | | |
| Description | Symbolic, non-editable station name | | | | | | | | | | | | | | | | | | | | | |
| RPI (ms) | Requested packet interval in milliseconds for a connection. For values in the microsecond range, the fixed point format can be used, e.g. 0.2 for 200 microseconds. | 0.001 to 4294967 (default: 100) | | | | | | | | | | | | | | | | | | | | |
| Timeout multiplier | Multiplication factor applied to the expected packet rate to obtain the connection timeout value. Whenever a timeout occurs during connection, modules should stop transmission over a connection, even if the pending closing signal has been transmitted. | <table border="1"> <thead> <tr> <th>Value</th> <th>Multiplier</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>x 4</td> </tr> <tr> <td>1</td> <td>x 8</td> </tr> <tr> <td>2</td> <td>x 16</td> </tr> <tr> <td>3</td> <td>x 32 (default)</td> </tr> <tr> <td>4</td> <td>x 64</td> </tr> <tr> <td>5</td> <td>x 128</td> </tr> <tr> <td>6</td> <td>x 256</td> </tr> <tr> <td>7</td> <td>x 512</td> </tr> <tr> <td>8 to 255</td> <td>Reserved</td> </tr> </tbody> </table> | Value | Multiplier | 0 | x 4 | 1 | x 8 | 2 | x 16 | 3 | x 32 (default) | 4 | x 64 | 5 | x 128 | 6 | x 256 | 7 | x 512 | 8 to 255 | Reserved |
| Value | Multiplier | | | | | | | | | | | | | | | | | | | | | |
| 0 | x 4 | | | | | | | | | | | | | | | | | | | | | |
| 1 | x 8 | | | | | | | | | | | | | | | | | | | | | |
| 2 | x 16 | | | | | | | | | | | | | | | | | | | | | |
| 3 | x 32 (default) | | | | | | | | | | | | | | | | | | | | | |
| 4 | x 64 | | | | | | | | | | | | | | | | | | | | | |
| 5 | x 128 | | | | | | | | | | | | | | | | | | | | | |
| 6 | x 256 | | | | | | | | | | | | | | | | | | | | | |
| 7 | x 512 | | | | | | | | | | | | | | | | | | | | | |
| 8 to 255 | Reserved | | | | | | | | | | | | | | | | | | | | | |

Process data

This table lists the process data of the individual Ethernet/IP adapters (slaves).

| Parameter | Explanation |
|-----------|---|
| Type | Device designation specified by the hardware. Further description of modules configured on the device or the input or output signals. |
| Day | The name of the input and output data can be changed in column "Day". |
| SCADA | This parameter is not supported. |

Address table

This table provides information about the addresses of the input and output data (in decimal or hexadecimal notation).

"Display mode" allows toggling between decimal and hexadecimal display.

| Parameter | Explanation |
|-----------------|-------------------------------------|
| Device | Device name of the adapter |
| Slot | Slot number for modular adapters |
| Connection name | Text-based name of the connection |
| Instance ID | Assembly instance ID |
| Length | Byte length of the instance |
| Address | Data offset address of the instance |

The address table can also be exported as a CSV file.

Quick connect table

This parameter is not supported.

Scanner settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

- Module alignment

The addressing mode is defined by the process image here. The addresses (offsets) of the process data are always interpreted as byte addresses.

| Addressing mode | Explanation |
|-------------------|---|
| Byte boundaries | The module address can start on any offset. |
| 2 byte boundaries | The module address can only start on even byte offsets. |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|---|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values Default value: 1000 ms | 20 to 65535 ms |

Information:

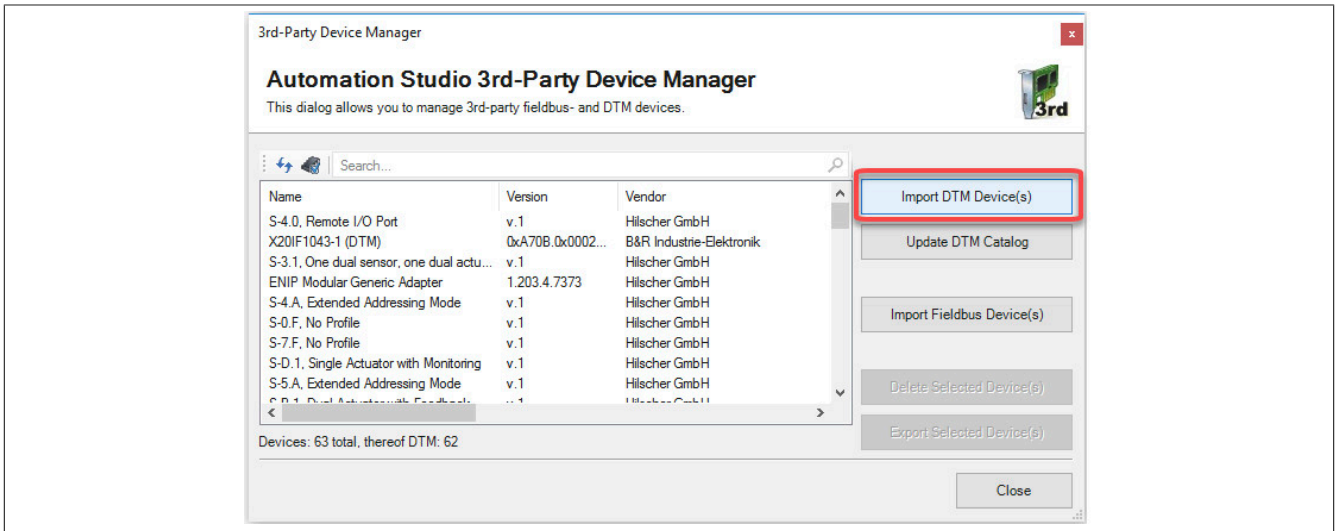

The watchdog time is reset automatically by Automation Runtime.

9.23.17.8.1.3 Adding the EDS file in Automation Studio

To tell the EtherNet/IP scanner (master) which adapters (slaves) were connected and how they were configured, a description file (EDS file) is required.

To add and use a device description file in Automation Studio, perform the following steps:

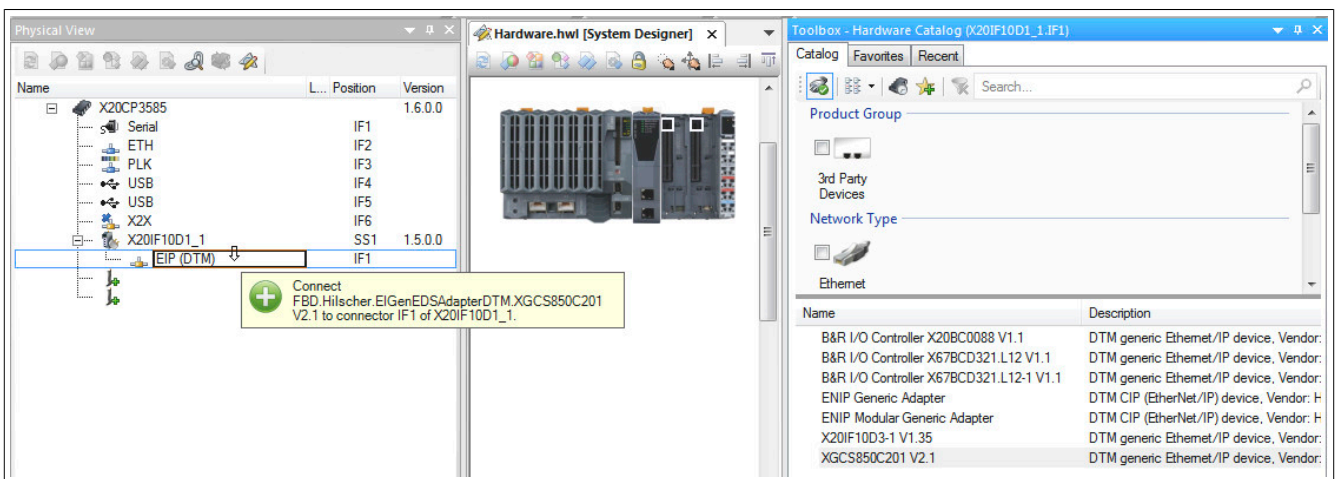

- If the B&R EtherNet/IP adapter (slave) is used, download the EDS file from the B&R website www.br-automation.com and unzip the ZIP file.
- Open the dialog box in Automation Studio under "Tools - Manage 3rd-party devices" and select "Import DTM device(s)".

- Select the EDS file to be imported and confirm with OK. The EDS file is imported into Automation Studio.

- Click on "EIP(DTM)" on EtherNet/IP scanner (master) X20IF10D1-1, drag the EDS file from the Hardware Catalog and attach it to the EtherNet/IP scanner (master).

- Right-click on the IF interface and select "Device configuration" to open the configuration environment for the EDS file.

9.23.18 X20(c)IF10D3-1

Data sheet version: 2.04

9.23.18.1 General information

The interface module is equipped with an EtherNet/IP adapter interface. This allows the B&R system (I/O modules, POWERLINK, etc.) to be connected to systems from other manufacturers and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

The interface is equipped with 2 RJ45 connections. Both connections result in an integrated switch. This makes it easy to implement daisy chain cabling.

- EtherNet/IP adapter (slave)
- Integrated switch for efficient cabling

9.23.18.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.18.2.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.23.18.3 Order data

| Model number | Short description | Figure |
|--------------|---|--------|
| | X20 interface module communication | |
| X20IF10D3-1 | X20 interface module, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated | |
| X20cIF10D3-1 | X20 interface module, coated, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated | |

Table 456: X20IF10D3-1, X20cIF10D3-1 - Order data

Optional accessories

| Model number | Short description |
|-----------------|--|
| X20CA0E61.xxxxx | POWERLINK/Ethernet connection cable, RJ45 to RJ45, 0.2 to 20 m |
| X20CA0E61.xxx | POWERLINK/Ethernet connection cable, RJ45 to RJ45, 20 m and longer |

| | | Green | Off | No power to module |
| | | | Blinking | No active connection |
| | | | On | Indicates at least one active connection |
| | L/A IF1/IF2 | Red | Blinking | Timeout occurred on at least one connection |
| | | | On | An IP address has been used repeatedly |
| | | Green/red | Blinking | Initialization / Self-test |
| Off | | | No IP address assigned or module not supplied | |
| L/A IF1/IF2 | Green | Off | No link to remote station | |
| | | Flickering | A link to the remote station has been established. The LED blinks when Ethernet activity is taking place on the bus. | |
| | | On | A link to the remote station has been established. | |

1) This LED is a green/red dual LED.

9.23.18.5.2 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see "Cabling guidelines for X20 modules with an Ethernet cable" on page 58.

| Interface | Pinout | | |
|-------------------|--------|-------------|----------------|
| | Pin | Ethernet | |
| Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.23.18.6 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.18.6.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.18.6.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.18.7 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.18.8 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.18.9 Minimum DTM version for coated modules

Information:

The minimum DTM version required for coated modules is 1.0370.140220.12186. This version is included starting with Automation Studio upgrade packs V4.0.18.x and V3.0.90.29.

9.23.18.10 EtherNet/IP interface

Two steps are generally necessary for connecting module X20IF10D3-1 to an external master environment.

- 1) Add and configure the X20 interface module in B&R's Automation Studio.
- 2) Add the EtherNet/IP adapter (slave) EDS device description file in the external master environment, e.g. Rockwell RSLogix 5000. The interface module must then be configured.

Information:

To ensure error-free EtherNet/IP communication between master and slave, the settings for the interface module in Automation Studio must match the settings of the EDS device description file in the master environment.

9.23.18.10.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

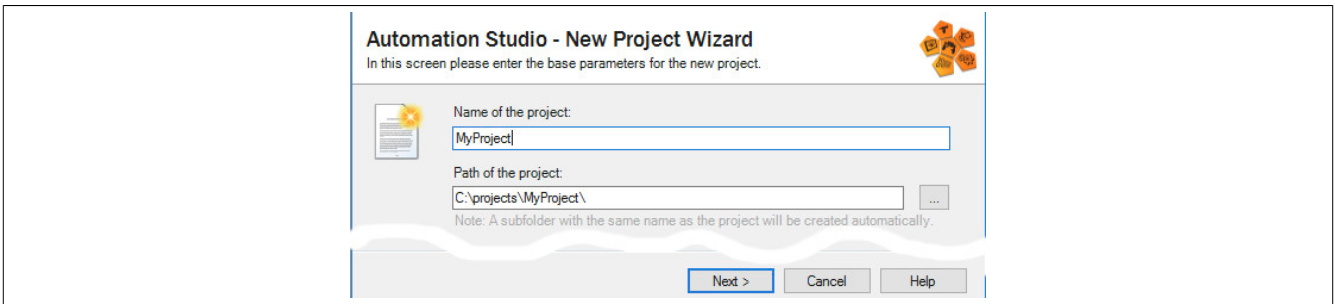

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.18.10.1.1 Creating an Automation Studio project

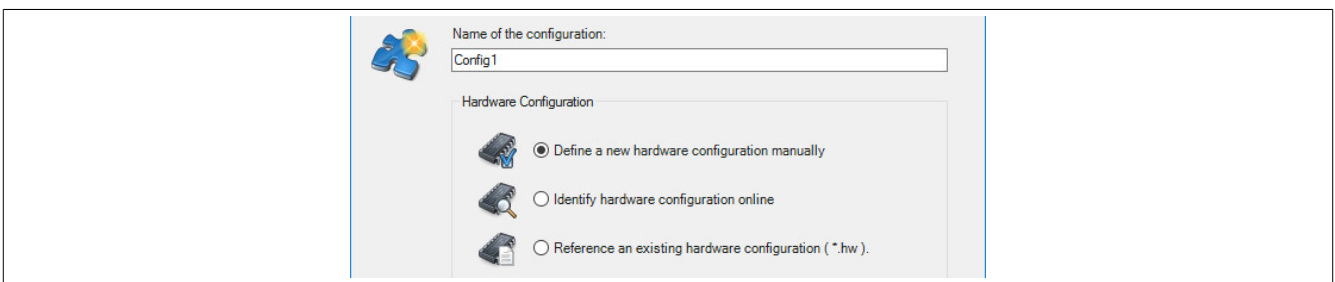

- Create a new Automation Studio project by selecting "New project".

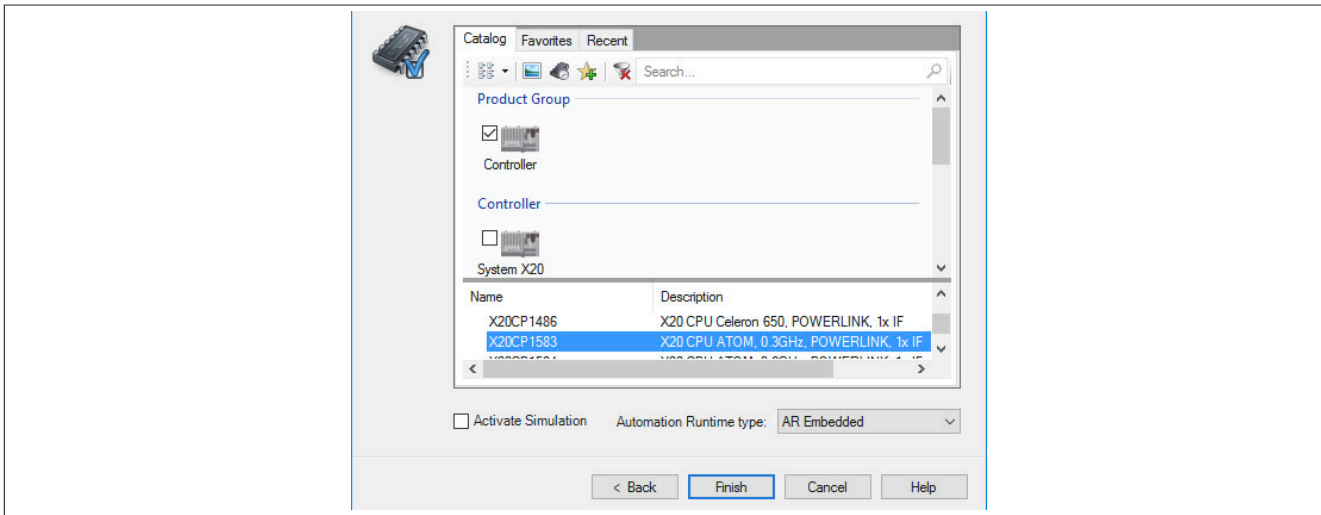

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

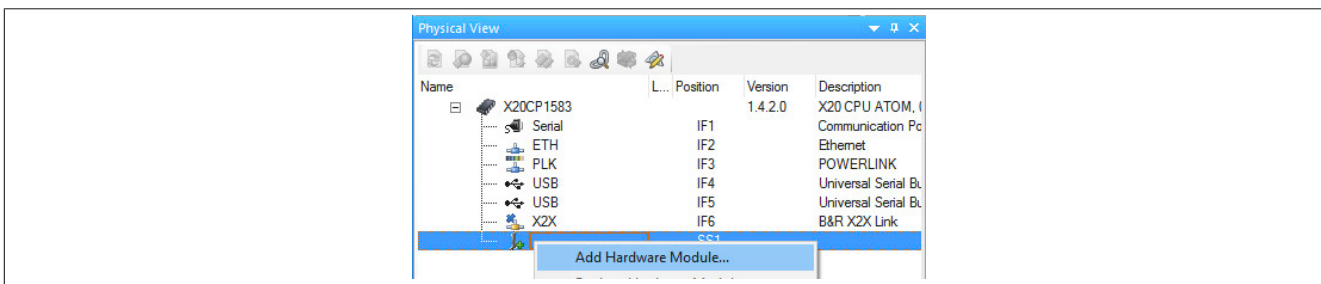

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

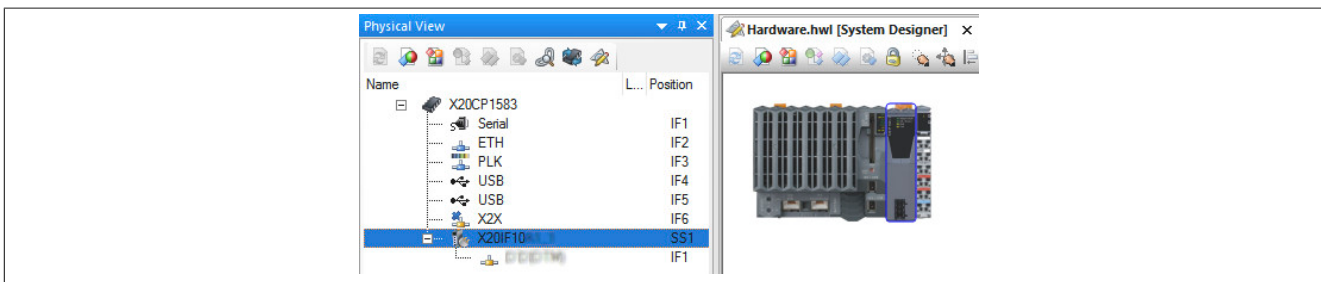

9.23.18.10.1.2 Adding and configuring the interface module

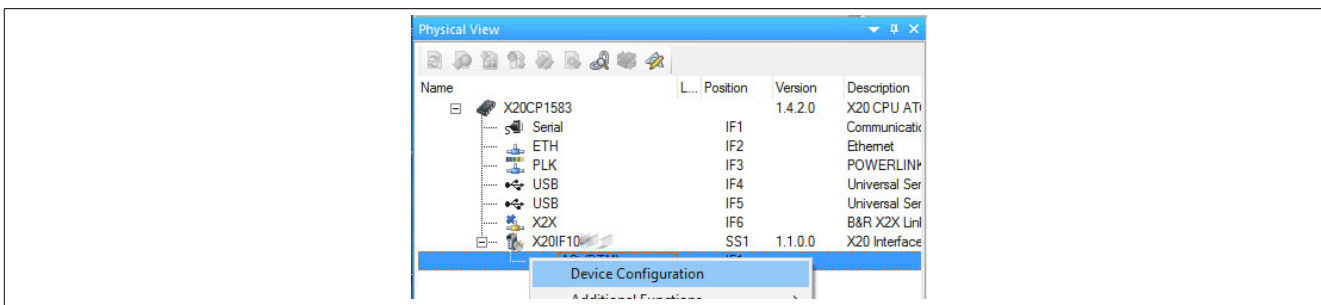

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

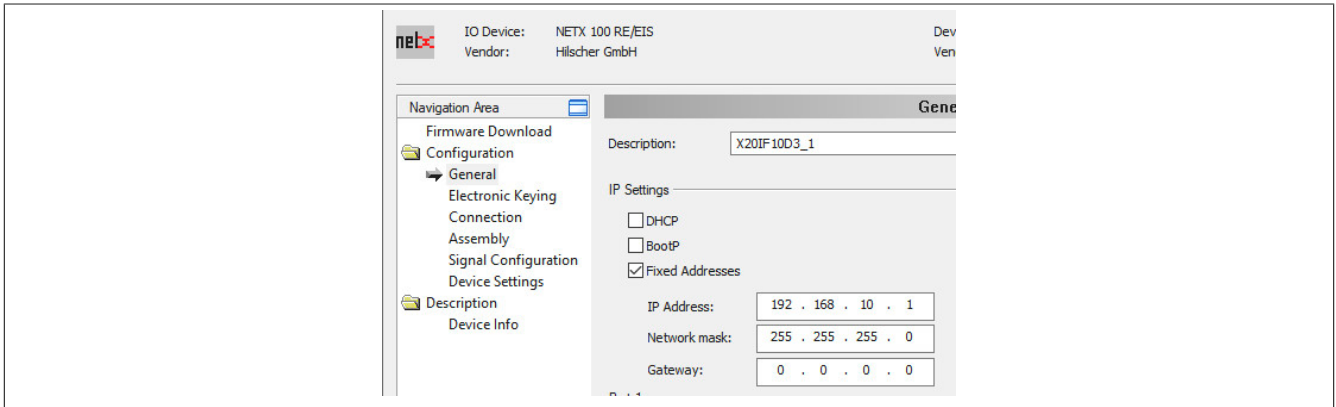

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

General

The IP settings and operation modes of the ports are set here. Only one of the IP settings can be enabled on the adapter (slave).

Contains the symbolic name of the module.

| Parameter | Explanation |
|-------------|----------------------------|
| Description | Module name of the adapter |

- IP settings

The IP addresses and operation modes of the Ethernet interface are set here.

| Parameter | Explanation |
|-----------------|--|
| DHCP | IP address determined via DHCP protocol. |
| BootP | IP address determined via BootP protocol. |
| Fixed addresses | The IP address is static. The IP address is defined by the following 3 parameters. |
| IP address | IP address of the EtherNet/IP adapter |
| Network mask | Network mask of the EtherNet/IP adapter |
| Gateway address | Gateway address of the EtherNet/IP adapter |

- Port 1

| Parameter | Explanation |
|----------------|--|
| Operating mode | Operating mode of the EtherNet/IP adapter (slave) |
| MDI mode | Configure cable type <ul style="list-style-type: none"> • Auto MDI-X: Detect cable type automatically • MDI-X: Use crossover cable. • MDI: Use straight-through cable. |

- Port 2

Identical to port 1

Electronic keying

Here, it is possible to set which parameters on the device and in the master's device description file must match exactly.

A connection between the EtherNet/IP scanner and the adapter can only be established if the parameter settings for the interface module in Automation Studio defined by the keying method match those in the EDS device description file.

| Method | Explanation |
|---------------|--|
| Exact match | When validating an EtherNet/IP adapter connected to the network, all attributes of the electronic identity must correspond to the attributes for an expected device. |
| Custom keying | When validating an EtherNet/IP adapter connected to the network, all attributes must correspond to the configured keying. |
| No keying | The device identity is not validated. |

If "Custom keying" is selected, the following parameters can be checked.

| Parameter | Explanation |
|----------------------|--|
| Relaxed match | Devices can verify their electronic identity in a restricted form. |
| Match minor revision | Checks for compliance with the secondary revision |
| Match major revision | Checks for compliance with the main revision |
| Match product code | Checks for compliance with the product code |
| Match product type | Checks for compliance with the product type |
| Match vendor | Checks for compliance with the vendor ID |

Connection

- Connection name

The name of the connection can be assigned here.

| Parameter | Explanation |
|-----------------|------------------------|
| Connection name | Name of the connection |

- Originator to target

The transfer format from the scanner to the adapter can be assigned here.

| Parameter | Explanation |
|--------------------|---|
| RT transfer format | Transfer format <ul style="list-style-type: none"> • Connection is pure data and is modeless • 32-bit run/idle header |

- Target to originator

The transfer format from the adapter to the scanner can be assigned here.

| Parameter | Explanation |
|--------------------|---|
| RT transfer format | Transfer format <ul style="list-style-type: none"> • Connection is pure data and is modeless • 32-bit run/idle header |

Information:

The default settings for "RT transfer format" can differ depending on the Automation Studio version / DTM version used.

The device description file package available on the B&R website contains 2 different EDS device description files:

- RT_Transfer_format_OT_32bit_TO_32bit
- RT_Transfer_format_OT_32bit_TO_modeless

The settings must be adjusted depending on the EDS file used. Inconsistencies will occur in the I/O image if the settings for the interface module do not match the settings in the EDS device description file in Automation Studio.

Assembly

Here is a list of input and output connections. The data length and the instance ID can be adjusted. If the instance ID or the length of the data is changed, this setting must also be adjusted in the master environment. Otherwise, no connection can be established from the scanner to the adapter.

| Parameter | Explanation | Values |
|-----------------|---|------------|
| In/Out | Input/Output connections of the EtherNet/IP adapter | |
| Connection name | Name of the input or output connection of the EtherNet/IP adapter | |
| Instance ID | Instance ID of the connection (editable) | 1 to 65535 |
| Data length | Data length in bytes (editable) | 0 to 504 |
| Min. length | Minimum data length in bytes | 0 |
| Max. length | Maximum data length in bytes | |

Signal configuration

The data structure of the individual modules can be defined here; the name and data type of the inputs and outputs can also be adjusted. Data types can also be combined.

| Parameter | Explanation |
|-------------|-----------------------|
| Slot | Position of the slot |
| Name | Name of the slot |
| Module type | Data type of the slot |

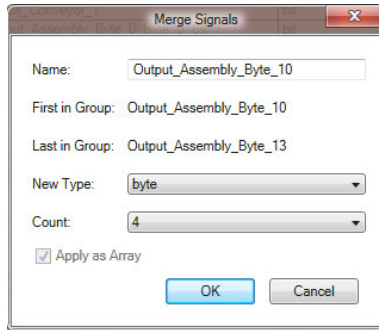

After selecting a slot, the type of the assembly (input or output), data type and offset are displayed in another table below.

After right-clicking on the signal to be configured, the following options can be selected in the shortcut menu:

- **Edit signal**

This allows the currently selected signal to be edited.

| Parameter | Explanation |
|----------------|--|
| Name | The new name for the signal |
| New type | The new data type for the signal |
| Count | Number of individually listed data type elements for the signal. Only the data of the original type is re-structured; the quantity is not adjusted. - The maximum number corresponds to the quantity that the new data type requires to display the original type. - If fewer elements are selected, the last data type element is listed as an array of all remaining elements. |
| Apply as array | If selected, the new data type is displayed as an array. Otherwise, the data type elements set under "Count" are displayed. |

| Slot | Name | Type | Offset |
|--------|-------------------------------------|--------------|--------|
| Slot 1 | Connection1 | | |
| | Status_Conveyor_1 | bit | 0.0 |
| | Output_Assembly_Byte_0_Byte_0_Bit_1 | bit | 0.1 |
| | Output_Assembly_Byte_0_Byte_0_Bit_2 | bit | 0.2 |
| | Output_Assembly_Byte_0_Byte_0_Bit_3 | bit | 0.3 |
| | Output_Assembly_Byte_0_Byte_0_Bit_4 | bit | 0.4 |
| | Output_Assembly_Byte_0_Byte_0_Bit_5 | bit | 0.5 |
| | Output_Assembly_Byte_0_Byte_0_Bit_6 | bit | 0.6 |
| | Output_Assembly_Byte_0_Byte_0_Bit_7 | bit | 0.7 |
| | Temp_1 | byte | 1 |
| | Position_5 | word | 2 |
| | Counter_10 | dword | 4 |
| | Output_Assembly_Byte_8 | byte | 8 |
| | Output_Assembly_Byte_9 | byte | 9 |
| | Output_Assembly_Byte_10 | 4 byte array | 10 |
| | Output_Assembly_Byte_13 | byte | 14 |
| | Output_Assembly_Byte_15 | byte | 15 |

- **Reset**

This can be used to undo the signal change or a merge previously completed with "Merge signal".

- **Merge signal**

This allows all signals between "First in group" and "Last in group" to be merged to form a new group. The same settings can be made for the new group as under "Edit signal".

The settings made are reflected in the process image (I/O mapping).

Configuring the signal

| Name | Type | Offset |
|-------------------------------------|-------|--------|
| Status_Conveyor_1 | bit | 0.0 |
| Output_Assembly_Byte_0_Byte_0_Bit_1 | bit | 0.1 |
| Output_Assembly_Byte_0_Byte_0_Bit_2 | bit | 0.2 |
| Output_Assembly_Byte_0_Byte_0_Bit_3 | bit | 0.3 |
| Output_Assembly_Byte_0_Byte_0_Bit_4 | bit | 0.4 |
| Output_Assembly_Byte_0_Byte_0_Bit_5 | bit | 0.5 |
| Output_Assembly_Byte_0_Byte_0_Bit_6 | bit | 0.6 |
| Output_Assembly_Byte_0_Byte_0_Bit_7 | bit | 0.7 |
| Temp_1 | byte | 1 |
| Position_5 | word | 2 |
| Counter_10 | dword | 4 |
| Output_Assembly_Byte_8 | byte | 8 |

Process image

| | | | | |
|---|---------|--------------------------|---------|-------|
| Connection1_Status_Conveyor_1 | TRUE | <input type="checkbox"/> | FALSE | BOOL |
| Connection1_Output_Assembly_Byte_0_Byte_0_Bit_1 | TRUE | <input type="checkbox"/> | FALSE | BOOL |
| Connection1_Output_Assembly_Byte_0_Byte_0_Bit_2 | TRUE | <input type="checkbox"/> | FALSE | BOOL |
| Connection1_Output_Assembly_Byte_0_Byte_0_Bit_3 | TRUE | <input type="checkbox"/> | FALSE | BOOL |
| Connection1_Output_Assembly_Byte_0_Byte_0_Bit_4 | TRUE | <input type="checkbox"/> | FALSE | BOOL |
| Connection1_Output_Assembly_Byte_0_Byte_0_Bit_5 | TRUE | <input type="checkbox"/> | FALSE | BOOL |
| Connection1_Output_Assembly_Byte_0_Byte_0_Bit_6 | TRUE | <input type="checkbox"/> | FALSE | BOOL |
| Connection1_Output_Assembly_Byte_0_Byte_0_Bit_7 | TRUE | <input type="checkbox"/> | FALSE | BOOL |
| Connection1_Temp_1 | 16#11 | <input type="checkbox"/> | 16#00 | USINT |
| Connection1_Position_5 | 16#3322 | <input type="checkbox"/> | 16#0000 | UINT |
| Connection1_Counter_10 | 16#7766 | <input type="checkbox"/> | 16#0000 | UDINT |
| Connection1_Output_Assembly_Byte_8 | 0 | <input type="checkbox"/> | 0 | USINT |

Device settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|---|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values Default value: 1000 ms | 20 to 65535 ms |

Information:

The watchdog time is reset automatically by Automation Runtime.

- Process image storage format

This parameter is not supported.

Description

General device information and the entire GSDML file can be read here.

9.23.18.10.2 EDS device description file

The module description is made available to the master in an EDS file. This file contains the description of the slave's complete range of functions. The EDS file can be downloaded from the B&R website (www.br-automation.com) in the Downloads section for the interface module and then imported into the respective master environment.

9.23.19 X20IF10E1-1

Data sheet version: 2.04

9.23.19.1 General information

The interface module is equipped with a PROFINET IO controller interface. This allows third-party components to be integrated in the B&R system and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

The interface is equipped with 2 RJ45 connections. Both connections result in an integrated switch. This makes it easy to implement daisy chain cabling.

- PROFINET IO controller
- Integrated switch for efficient cabling

| | | | Blinking | Configuration error: Not all configured I/O modules are connected | |
| | L/A IF1/IF2 | Green | On | No link to remote station | |
| | | | Off | No link to remote station | |
| | | | Flickering | A link to the remote station has been established. The LED blinks when Ethernet activity is taking place on the bus. | |
| | | | On | A link to the remote station has been established. | |

9.23.19.4.2 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see "[Cabling guidelines for X20 modules with an Ethernet cable](#)" on page 58.

| Interface | Pinout | | |
|----------------------|--------|-------------|----------------|
| | Pin | Ethernet | |
| <p>Shielded RJ45</p> | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.23.19.5 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.19.5.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.19.5.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.19.6 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.19.7 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.19.8 PROFINET IO interface

9.23.19.8.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

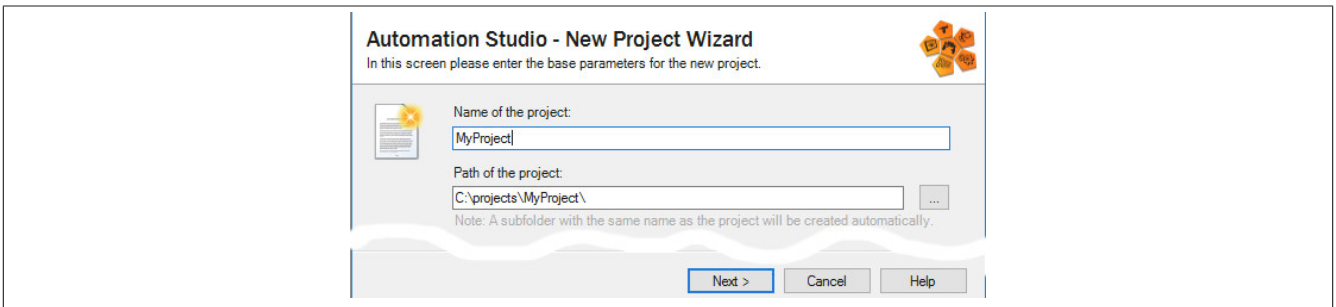

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.19.8.1.1 Creating an Automation Studio project

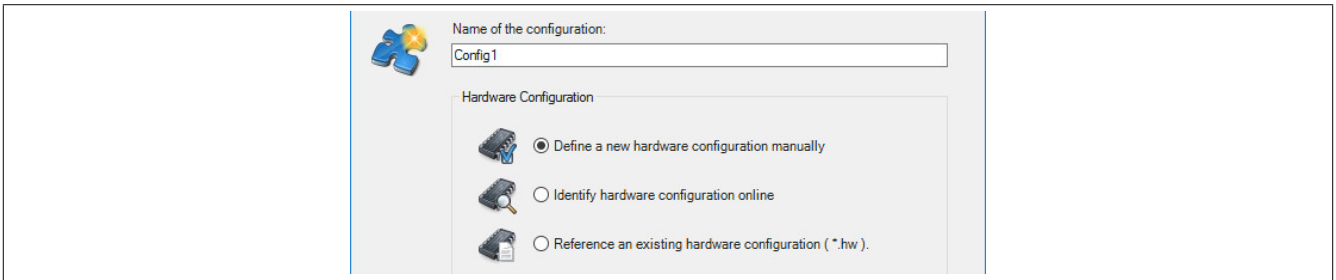

- Create a new Automation Studio project by selecting "New project".

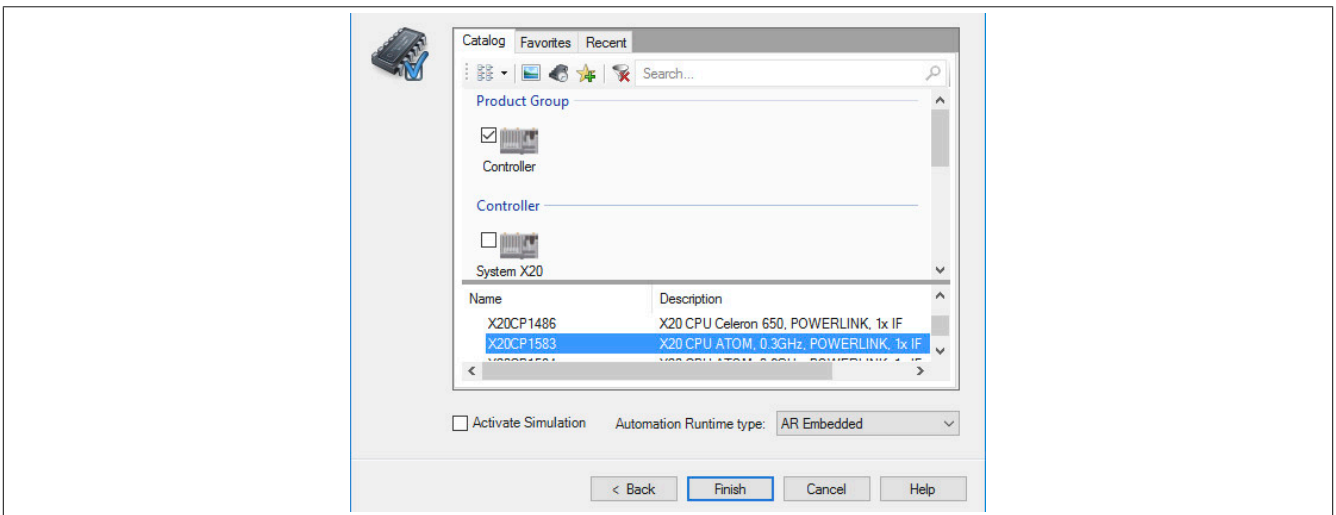

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

9.23.19.8.1.2 Adding and configuring the interface module

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

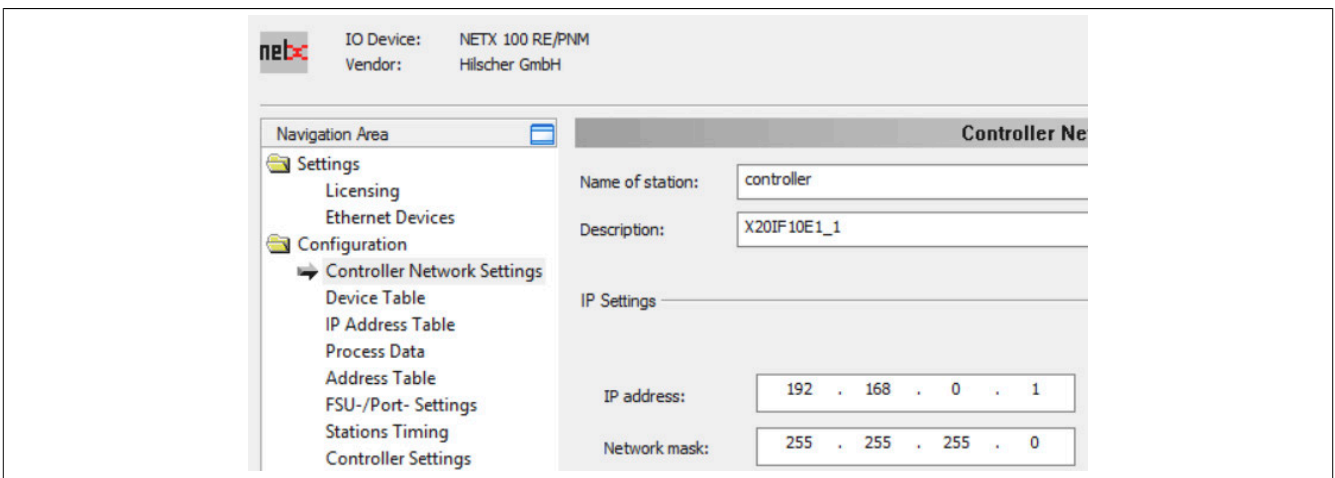

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

Controller network settings

Contains the name and symbolic name of the PROFINET IO controller.

| Parameter | Explanation | Values |
|-----------------|---------------|---------------------|
| Name of station | Name | 1 to 240 characters |
| Description | Symbolic name | |

- IP settings

Contains the IP address of the PROFINET IO controller.

| Parameter | Explanation |
|-----------------|-----------------|
| IP address | IP address |
| Network mask | Subnet mask |
| Gateway address | Gateway address |

Device table

All PROFINET IO devices configured on the PROFINET IO controller are listed here.

| Parameter | Explanation | Values |
|-----------------|---|---------------------|
| Activate | This allows the slaves to be enabled or disabled. <ul style="list-style-type: none"> • Enabled: Process memory is reserved and data is exchanged. • Disabled: The master reserves memory in the process data image for the slave, but no data is exchanged. | |
| Index | Consecutive numbering of the PROFINET IO devices in the scan list. | |
| Name of station | Editable station name. | 1 to 240 characters |
| Device | Physical, non-editable station name | |
| Description | Symbolic, non-editable station name | |
| Vendor | Vendor information | |

IP address table

The IP addresses of the slaves are set here.

| Parameter | Explanation |
|-----------------|---|
| Name of station | Network name of the PROFINET station. The value is set in the DTM of the PROFINET IO controller. |
| IP address | IP address of the PROFINET station |
| Inherit | This permits the network mask and gateway address to be obtained from the master. <ul style="list-style-type: none"> • Selected: Network mask and gateway address are obtained from the master. • Not selected: The network mask and gateway address are configured manually. |
| Network mask | Subnet mask of the PROFINET station. |
| Gateway address | Gateway address of the PROFINET station |

Process data

This table lists the process data of the individual slaves.

| Parameter | Explanation |
|-----------|---|
| Type | Device designation specified by the hardware. Further description of modules configured on the device or the input or output signals. |
| Tag | Name of the input or output data. |
| SCADA | This parameter is not supported. |

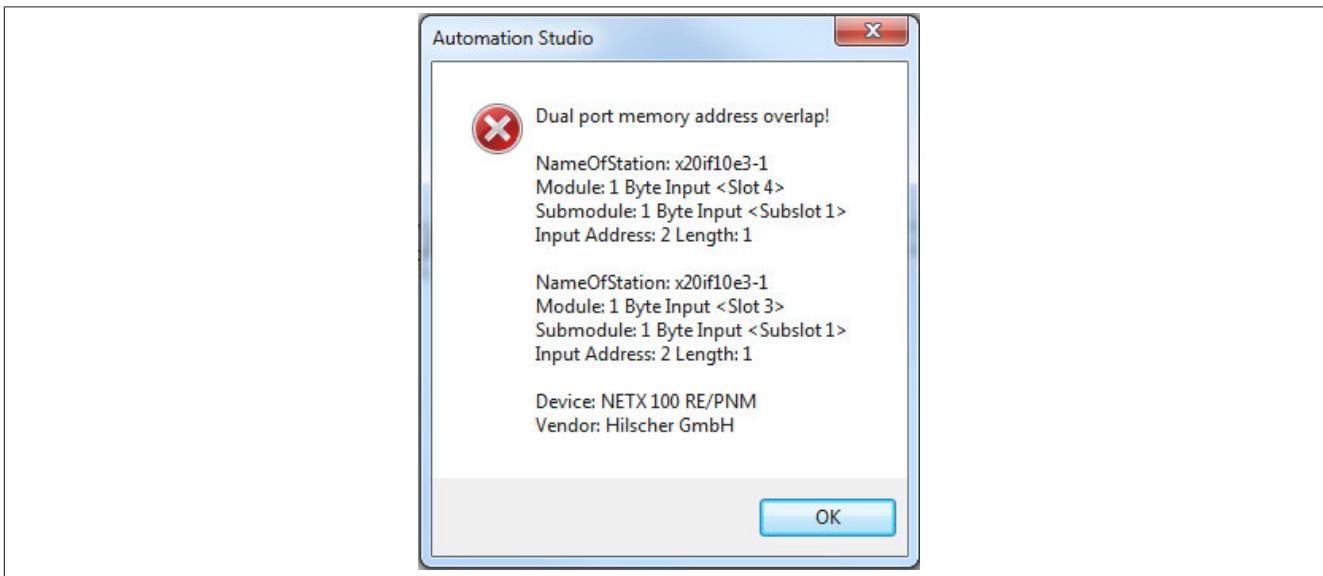

Address table

This table provides information about the addresses of the input and output data (in decimal or hexadecimal notation).

Auto addressing is used to select whether the addresses are assigned automatically or manually.

Information:

If addresses are assigned twice, an error is output and the addresses affected are marked with a red exclamation mark.

"Display mode" allows toggling between decimal and hexadecimal display.

| Parameter | Explanation |
|-----------------|--|
| Name of station | Network name of the PROFINET station. The value is set in the DTM of the PROFINET IO controller. |
| Modules | Module name |
| Submodule | Submodule name |
| Type | Data type |
| Length | Length of the module/submodule in bytes. |
| Address | Data offset address |

The address table can also be exported as a CSV file.

FSU / Port settings

The medium attachment unit (MAU) type can be set and fast startup (FSU) enabled here.

| Parameter | Explanation |
|-----------------|--|
| Name of station | Network name of the PROFINET station. The value is set in the DTM of the PROFINET IO controller. |
| MAU type | The MAU type must be set individually for each interface. <ul style="list-style-type: none"> • Auto: The connection between 2 adjacent devices is established automatically and takes about 2 to 3 seconds. • 100BASETXFD: The connection between adjacent devices is established with 100 Mbit / full-duplex. |
| FSU | Enables or disables FSU (fast startup). <p>If FSU is enabled, MAU type "100BASETXFD" should always be used, otherwise autonegotiation and auto-crossover (with MAU type = "AUTO") prevent a fast Ethernet connection.</p> |

Information:

The interfaces that are connected to each other must have the same MAU type; otherwise, no connection can be established. When FSU is enabled, the slave uses the fast start up connection to establish the cyclic data exchange.

Station timing

The timing of the individual PROFINET devices can be adjusted here.

| Parameter | Explanation |
|-----------------|---|
| Name of station | Device names of all PROFINET IO devices connected to the PROFINET IO controller. |
| Updating time | Configurable cycle time of the PROFINET IO device for exchanging cyclic data. |
| Watchdog time | Time after which the PROFINET IO device reports the absence of cyclic data and changes to the error state. The watchdog time must be a multiple of the update time. |

Information:

Different update and watchdog times can be set for each PROFINET IO device.

Controller settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

- Module alignment

The addressing mode is defined by the process image here. The addresses (offsets) of the process data are always interpreted as byte addresses.

| Addressing mode | Explanation |
|-------------------|---|
| Byte boundaries | The module address can start on any offset. |
| 2 byte boundaries | The module address can only start on even byte offsets. |

Information:

This configuration is automatically managed by Automation Runtime and is not permitted to be changed (default setting).

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|---|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values Default value: 1000 ms | 20 to 65535 ms |

Information:

The watchdog time is reset automatically by Automation Runtime.

Information:

This value refers exclusively to the software watchdog and not to the PROFINET watchdog time set in the station timing.

- Process image storage format

This is used to define how data is stored in the process image (I/O mapping). The storage format is only applied to data type "Word". This change has no effect on other data types.

| Storage format | Explanation |
|----------------|---|
| Big-endian | MSB/LSB = Higher/Lower byte (Motorola format) |
| Little-endian | MSB/LSB = Higher/Lower byte (Intel format) |

Input process image

Storage format - Little-endian (default setting)

| | | | | | | | | | |
|--------------------|---------|--------------------------|---------|-------|--------------------|---------|--------------------------|---------|-------|
| Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT | Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT |
| Module003_Input_2 | 16#3344 | <input type="checkbox"/> | 16#0000 | UINT | Module003_Input_2 | 16#4433 | <input type="checkbox"/> | 16#0000 | UINT |
| Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT | Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT |

Storage format - Big-endian

| | | | | | | | | | |
|--------------------|---------|--------------------------|---------|-------|--------------------|---------|--------------------------|---------|-------|
| Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT | Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT |
| Module003_Input_2 | 16#3344 | <input type="checkbox"/> | 16#0000 | UINT | Module003_Input_2 | 16#4433 | <input type="checkbox"/> | 16#0000 | UINT |
| Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT | Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT |

— Port settings

The settings must be made separately for each of the 2 interfaces.

| Setting | Explanation |
|-------------|--|
| Auto | The connection between 2 adjacent devices is established automatically and takes about 2 to 3 seconds. |
| 100BASETXFD | The connection between adjacent devices is established with 100 Mbit / full-duplex. |

Information:

The interfaces that are connected to each other must have the same settings; otherwise, no connection can be established.

— I/O state information

The IOPS interface can be configured here. If configured, the PROFINET input/output object provider state (IOPS) permits the PROFINET IO device application program to recognize whether the received data from the PROFINET device is valid or not and declares the output data as valid or invalid.

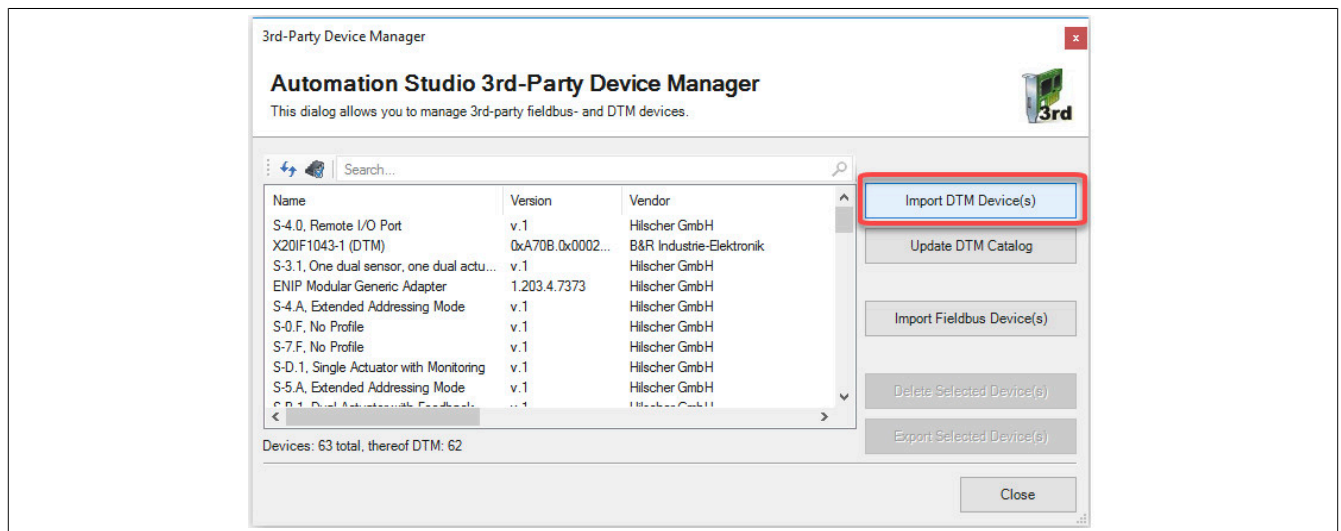

| Setting | Explanation |
|----------|--|
| Disabled | I/O state information disabled. |
| Bit | The IOPS is treated as a bit list in the DPM (Dual Port Memory) of the PROFINET IO device. For this purpose, 2 I/O data points (InIOPS and OutIOPS) are listed in the I/O assignment for the individual input and output data. <ul style="list-style-type: none"> Respective bit set to 1: Data is valid. Respective bit set to 0: Data is invalid. |
| Byte | The IOPS is treated as a byte array in the dual-ported memory (DPM) of the PROFINET IO device. For this purpose, 2 I/O data points (InIOPS and OutIOPS) are listed in the I/O assignment for the individual input and output data of the slave. <ul style="list-style-type: none"> Respective byte set to 0x80: Data is valid. Respective bit set to not equal to 0x80: Data is invalid. |

9.23.19.8.1.3 Adding the GSD file in Automation Studio

A device description file (GSDML file) is required to inform the PROFINET IO controller which slaves were connected and how they were configured.

To add and use a device description file in Automation Studio, perform the following steps:

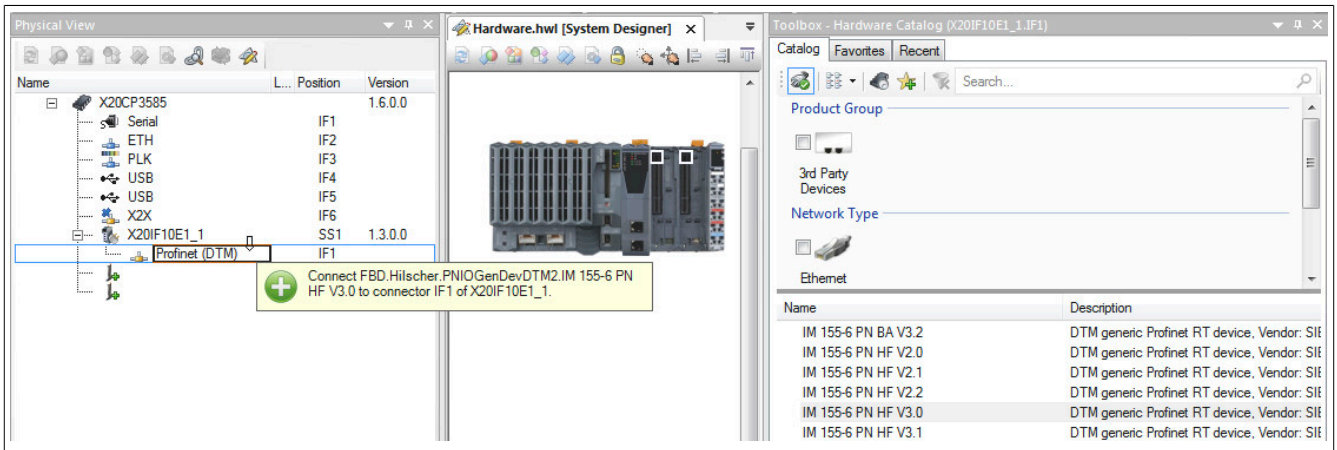

- If the PROFINET slave from B&R is used, download the GSDML file from the B&R website www.br-automation.com and unzip the ZIP file.
- Open the dialog box in Automation Studio under "Tools - Manage 3rd-party devices" and select "Import DTM device(s)".

- Select the GSDML file to be imported and confirm with OK. The GSDML file is imported into Automation Studio.

- Click on "PROFINET (DTM)" on PROFINET IO controller X20IF10E1-1, drag the GSDML file from the Hardware Catalog and attach it to the PROFINET IO controller.

- Right-click on the IF interface and select "Device configuration" to open the configuration environment for the GSDML file.

9.23.20 X20(c)IF10E3-1

Data sheet version: 2.08

9.23.20.1 General information

The interface module is equipped with a PROFINET IO device interface. This allows the B&R system (I/O modules, POWERLINK, etc.) to be connected to systems from other manufacturers and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

The interface is equipped with 2 RJ45 connections. Both connections result in an integrated switch. This makes it easy to implement daisy chain cabling.

- PROFINET IO device
- Integrated switch for efficient cabling

9.23.20.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.20.3 Order data

| Model number | Short description | Figure |
|--------------|---|--------|
| | X20 interface module communication | |
| X20IF10E3-1 | X20 interface module, for DTM configuration, 1 PROFINET IO device (slave) interface module, electrically isolated | |

9.23.20.5 Operating and connection elements

9.23.20.5.1 LED status indicators

| Figure | LED | Color | Status | Description | |
|--------|-------------|-----------|---|--|----------|
| | READY/RUN | Green/red | Off | No power to module | |
| | | Red | Blinking | Boot error | |
| | | On | Communication on the PCI bus has not yet been started | | |
| | SF | Green | On | PCI bus communication in progress | |
| | | | Red | Off | No error |
| | | | Cyc. Blinking ¹⁾ | DCP signal service triggered via bus | |
| | BF | Red | On | System errors | |
| | | | Off | No error | |
| | | | Blinking | No data exchange | |
| | L/A IF1/IF2 | Green | On | No configuration or physical connection error | |
| | | | Off | No link to remote station | |
| | | | Flickering | A link to the remote station has been established. The LED blinks when Ethernet activity is taking place on the bus. | |
| | | | On | A link to the remote station has been established. | |

1) Blinks cyclically at 2 Hz, duration 3 s.

9.23.20.5.2 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see "Cabling guidelines for X20 modules with an Ethernet cable" on page 58.

| Interface | Pinout | | |
|-------------------|--------|-------------|----------------|
| | Pin | Ethernet | |
| Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.23.20.6 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.20.6.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.20.6.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision \geq E0 is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.20.7 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.20.8 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.20.9 Recognizing an invalid connection

All cyclic data is set to zero in the event of an invalid connection between the master and slave.

An invalid connection may be caused by the following:

- No connection between the master and the slave
- Interface card initialization is not yet complete.
- The master is in error mode.
- Data is marked as invalid (IOPS = Bad).

It cannot be determined whether the data is valid or invalid based on the transmitted data. In order to be able to reliably recognize an invalid connection, it is necessary to evaluate the master's IOPS data additionally in the application.

Forwarding IOPS data to the application can be enabled via the interface card's DTM ("I/O state information" in Automation Studio).

9.23.20.10 Minimum DTM version for coated modules

Information:

This module requires at least version 1.0.2.14 of DTM, which can be downloaded from the B&R website www.br-automation.com in category "Software/DTM" of the Downloads section.

9.23.20.11 PROFINET IO interface

2 steps are generally necessary for connecting module X20IF10E3-1 to an external master environment.

- 1) Add and configure the X20 interface module in B&R's Automation Studio.
- 2) Add the PROFINET device (slave) GSDML device description file in the external master environment, e.g. Siemens STEP 7 or Siemens TIA-Portal. The interface module must then be configured.

Information:

To ensure error-free PROFINET communication between controller (master) and device (slave), the settings for the interface module in Automation Studio must match the settings of the GSDML device description file in the master environment.

9.23.20.11.1 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.20.11.1.1 Creating an Automation Studio project

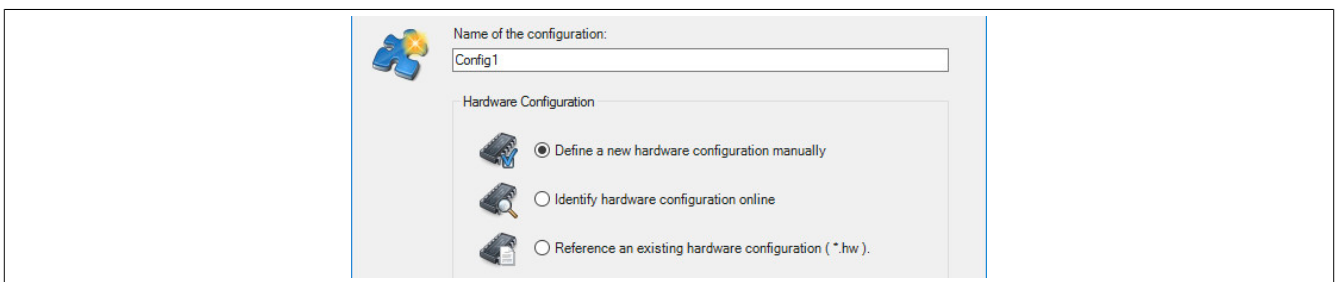

- Create a new Automation Studio project by selecting "New project".

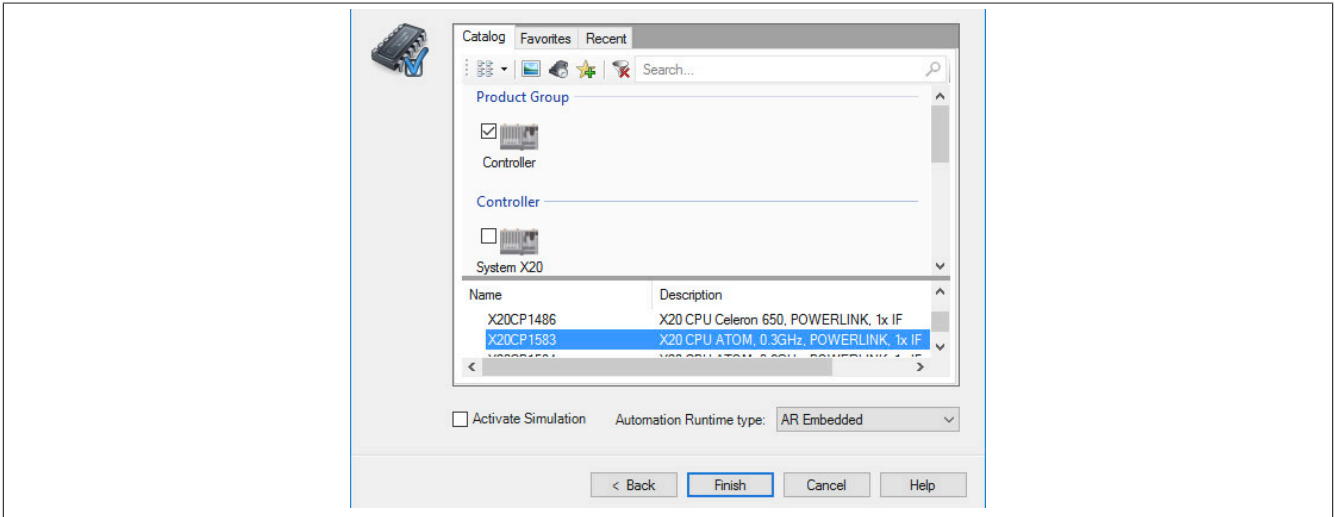

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

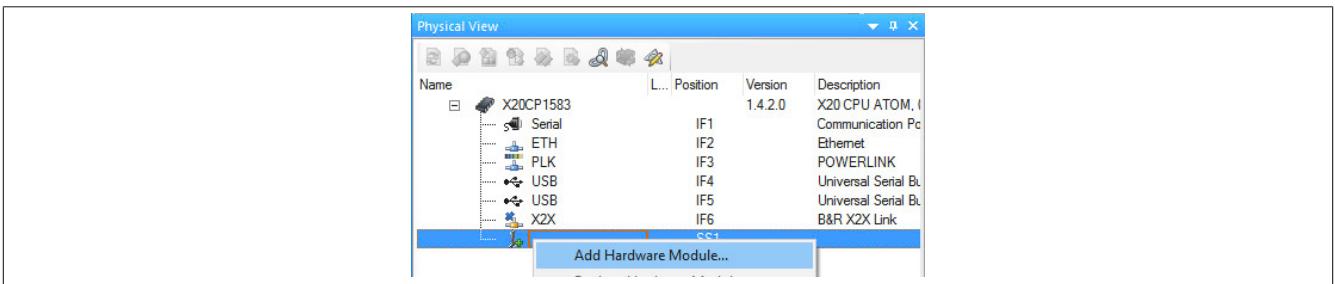

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

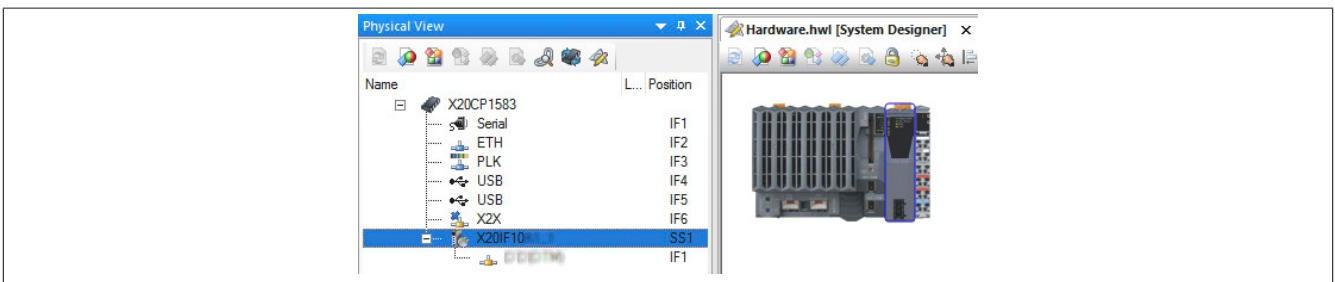

9.23.20.11.1.2 Adding and configuring the interface module

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

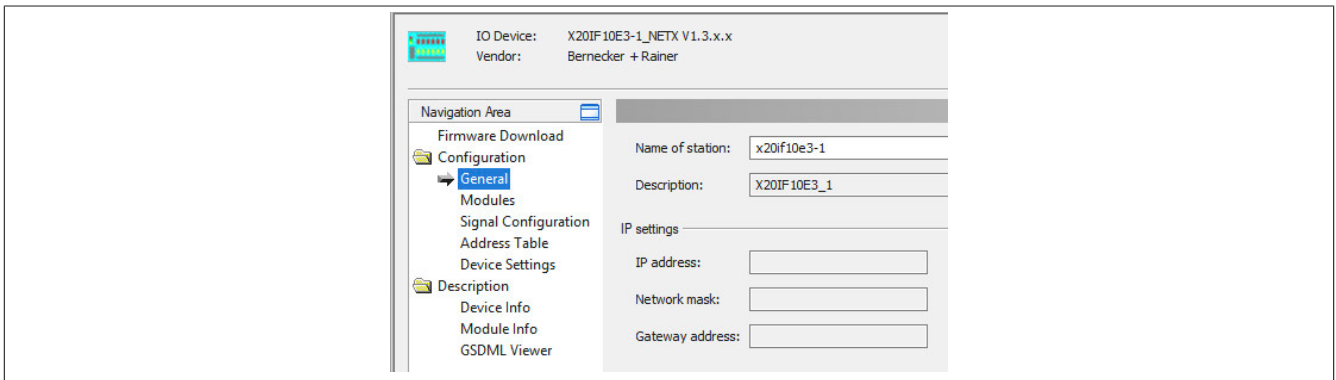

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

- General settings are made in the device configuration.

General

The name of the station (slave) can be set here.

All other parameters are defined at the master. The PROFINET IO device (slave) is identified by the station name. As soon as there is a connection from the controller to the PROFINET IO device (slave), the other parameters (IP address, network mask, etc.) are transferred to the PROFINET IO device (slave).

Modules

Modules can be added to the PROFINET IO device (slave) here.

| Parameter | Explanation | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----------|---|--|---|--|--|--|--------------|--|--|--------------|--|--|---------------|--|--|---------------|--|--|---------------|--|--|---------------|--|--|--------------------|--|--|---------------------|--|--|--------------------|--|--|---------------------|--|--|--------------------|
| | Selecting a submodule If a submodule is selected, more detailed information about the submodule is displayed in the lower table. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Slot | Shows the current slot number assigned to a module. The sequence of the modules can be changed by changing the slot number. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Subslot | Shows the current subslot number assigned to a module. The sequence of the modules can be changed by changing the subslot number. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| ! | Slot symbol: Indicates the use of the (sub)modules. <ul style="list-style-type: none"> • No symbol: (Sub)slot number and name can be changed. • Pin symbol: No change possible | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Modules | The module type can be changed by selecting the desired type in the dropdown box. <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <table border="1"> <tr> <td>!</td> <td>✕</td> <td>X20IF10E3-1_NETX V1.3.x.x [X20IF10E3-1 V1.3.x.x]</td> </tr> <tr> <td></td> <td></td> <td>1 Byte Input</td> </tr> <tr> <td></td> <td></td> <td>1 Byte Input</td> </tr> <tr> <td></td> <td></td> <td>2 Bytes Input</td> </tr> <tr> <td></td> <td></td> <td>3 Bytes Input</td> </tr> <tr> <td></td> <td></td> <td>4 Bytes Input</td> </tr> <tr> <td></td> <td></td> <td>8 Bytes Input</td> </tr> <tr> <td></td> <td></td> <td>1 Unsigned16 Input</td> </tr> <tr> <td></td> <td></td> <td>1 Unsigned32 Output</td> </tr> <tr> <td></td> <td></td> <td>1 Unsigned32 Input</td> </tr> <tr> <td></td> <td></td> <td>1 Unsigned64 Output</td> </tr> <tr> <td></td> <td></td> <td>1 Unsigned64 Input</td> </tr> </table> </div> | ! | ✕ | X20IF10E3-1_NETX V1.3.x.x [X20IF10E3-1 V1.3.x.x] | | | 1 Byte Input | | | 1 Byte Input | | | 2 Bytes Input | | | 3 Bytes Input | | | 4 Bytes Input | | | 8 Bytes Input | | | 1 Unsigned16 Input | | | 1 Unsigned32 Output | | | 1 Unsigned32 Input | | | 1 Unsigned64 Output | | | 1 Unsigned64 Input |
| ! | ✕ | X20IF10E3-1_NETX V1.3.x.x [X20IF10E3-1 V1.3.x.x] | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 1 Byte Input | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 1 Byte Input | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 2 Bytes Input | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 3 Bytes Input | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 4 Bytes Input | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 8 Bytes Input | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 1 Unsigned16 Input | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 1 Unsigned32 Output | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 1 Unsigned32 Input | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 1 Unsigned64 Output | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 1 Unsigned64 Input | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

"Add module" adds the default module "1 byte input" to the slave. This module can be changed via the dropdown menu in column "Modules".

Use "Remove" to remove the modules again.

— Submodule details

"Dataset" can be used to toggle between I/O data and parameters.

"Display mode" allows toggling between decimal and hexadecimal display.

The modules are simple input and output modules. These have no adjustable parameters. I/O data cannot be changed in this table.

Signal configuration

The data structure of the individual modules can be defined here; the name and data type of the inputs and outputs can also be adjusted. Data types can also be combined.

| Parameter | Explanation |
|-------------|--|
| Slot | Position of the slot |
| Name | Name of the slot |
| Module type | Number of bytes and type of connection (input or output) |

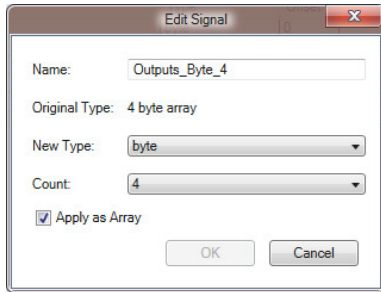

After selecting a slot, the type, data type and offset are displayed in another table below.

After right-clicking on the signal to be configured, the following options can be selected in the shortcut menu:

- **Edit signal**

This allows the currently selected signal to be edited.

| Parameter | Explanation |
|----------------|--|
| Name | The new name for the signal |
| New type | The new data type for the signal |
| Count | Number of individually listed data type elements for the signal. Only the data of the original type is re-structured; the quantity is not adjusted. - The maximum number corresponds to the quantity that the new data type requires to display the original type. - If fewer elements are selected, the last data type element is listed as an array of all remaining elements. |
| Apply as array | If selected, the new data type is displayed as an array. Otherwise, the data type elements set under "Count" are displayed. |

| Slot | Name |
|--------------------|---------------------------------|
| Slot 1 / Subslot 1 | 8 Bytes Input / 8 Bytes Input |
| Slot 2 / Subslot 1 | 8 Bytes Output / 8 Bytes Output |

| Name | Type | Offset |
|----------------|--------------|--------|
| Outputs_Byte_0 | byte | 0 |
| Outputs_Byte_1 | byte | 1 |
| Outputs_Byte_2 | byte | 2 |
| Outputs_Byte_3 | byte | 3 |
| Outputs_Byte_4 | 4 byte array | 4 |

- **Reset**

This can be used to undo the signal change or a merge previously completed with "Merge signal".

- **Merge signal**

This allows all signals to be merged into a new group. The same settings can be made for the new group as under "Edit signal".

The settings made are reflected in the process image (I/O mapping).

Configuring the signal

| Slot | Name |
|--------|------------|
| Slot 1 | 8 Bytes In |

| Name | Type | Offset |
|----------------------|-------|--------|
| Temp_1 | byte | 0 |
| Pressure_5 | byte | 1 |
| Input_3_Byte_0_Bit_0 | bit | 2.0 |
| Input_3_Byte_0_Bit_1 | bit | 2.1 |
| Input_3_Byte_0_Bit_2 | bit | 2.2 |
| Input_3_Byte_0_Bit_3 | bit | 2.3 |
| Input_3_Byte_0_Bit_4 | bit | 2.4 |
| Input_3_Byte_0_Bit_5 | bit | 2.5 |
| Input_3_Byte_0_Bit_6 | bit | 2.6 |
| Input_3_Byte_0_Bit_7 | bit | 2.7 |
| Input_4 | byte | 3 |
| Counter_Airflow_1 | dword | 4 |

Process image

| | | | | |
|--------------------------------|-------|--------------------------|-------|-------|
| Module001_Temp_1 | 0 | <input type="checkbox"/> | 0 | USINT |
| Module001_Pressure_5 | 0 | <input type="checkbox"/> | 0 | USINT |
| Module001_Input_3_Byte_0_Bit_0 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_1 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_2 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_3 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_4 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_5 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_6 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_3_Byte_0_Bit_7 | FALSE | <input type="checkbox"/> | FALSE | BOOL |
| Module001_Input_4 | 0 | <input type="checkbox"/> | 0 | USINT |
| Module001_Counter_Airflow_1 | 0 | <input type="checkbox"/> | 0 | UDINT |

Address table

This table provides information about the addresses of the input and output data (in decimal or hexadecimal notation).

"Display mode" allows toggling between decimal and hexadecimal display.

| Parameter | Explanation |
|-----------|---|
| Modules | Name of the module |
| Submodule | Name of the submodule |
| Type | Data type |
| Length | Length of the module/submodule in bytes |
| Address | Offset address of the data |

The address table can also be exported as a CSV file.

Device settings

- Start of bus communication

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

Information:

Parameter "Manual start of bus communication" can be enabled under the I/O configuration of the PROFINET IO device (slave).

| Name | Value | Unit | Description |
|-----------------------------------|----------|------|-------------------------------------|
| X20IF10E3_1 | | | |
| Function model | standard | | Module's operating mode |
| FDT/DTM | | | |
| netX configuration module | asrxd2 | | Module containing the netX configu |
| Data exchange time (CPU-netX) | 10000 | µs | Cycle time for data exchange betwe |
| Manual start of bus communication | on | | If set to on, bus communication has |
| Channel configuration | | | |
| Module001 | | | 1 Byte Input |
| Output Image | | | 1 Byte(s) |
| Channel 1 | | | |
| Name | TODO | | |
| Data type | BOOL | | |

The following settings must be made in order to avoid automatic data exchange:

- In the IF module configuration, "Manual start of bus communication" must be set to "On".
- "Start of bus communication" must be set to "Controlled by application".

With this setting, the communication can only be started via function block **AsNxPnS - nxpnsStartBusComm()**.

- Application monitoring

The module-internal watchdog time can be set here. If the watchdog has been enabled (watchdog time not equal to 0), the hardware watchdog must be reset after the set time at the latest.

| Parameter | Explanation | Values |
|---------------|-----------------------------|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values | 20 to 65535 ms |
| | Default value: 1000 ms | |

Information:

The watchdog time is reset automatically by Automation Runtime.

Information:

This value refers exclusively to the software watchdog and not to the PROFINET watchdog time set in the PROFINET IO controller.

- Process image storage format

This is used to define how data is stored in the process image (I/O mapping). The storage format is only applied to data type "Word". This change has no effect on other data types.

| Storage format | Explanation |
|----------------|---|
| Big-endian | MSB/LSB = Higher/Lower byte (Motorola format) |
| Little-endian | MSB/LSB = Higher/Lower byte (Intel format) |

Storage format - Little-endian (default setting)

| | | | | |
|----------------------|---------|--------------------------|---------|-------|
| ➔ Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT |
| ➔ Module003_Input_2 | 16#3344 | <input type="checkbox"/> | 16#0000 | UINT |
| ➔ Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT |

Storage format - Big-endian

| | | | | |
|----------------------|---------|--------------------------|---------|-------|
| ➔ Module002_Output_1 | 16#00 | <input type="checkbox"/> | 16#00 | USINT |
| ➔ Module003_Input_2 | 16#4433 | <input type="checkbox"/> | 16#0000 | UINT |
| ➔ Module004_Output_2 | 16#0000 | <input type="checkbox"/> | 16#0000 | UINT |

— I/O state information

The IOPS interface can be configured here. If configured, the PROFINET input/output object provider state (IOPS) permits the PROFINET IO device application program to recognize whether the received data from the PROFINET device is valid or not and declares the output data as valid or invalid.

| Setting | Explanation |
|----------|--|
| Disabled | I/O state information disabled. |
| Bit | The IOPS is treated as a bit list in the DPM (Dual Port Memory) of the PROFINET IO device. For this purpose, 2 I/O data points (InIOPS and OutIOPS) are listed in the I/O assignment for the individual input and output data. <ul style="list-style-type: none"> Respective bit set to 1: Data is valid. Respective bit set to 0: Data is invalid. |
| Byte | The IOPS is treated as a byte array in the dual-ported memory (DPM) of the PROFINET IO device. For this purpose, 2 I/O data points (InIOPS and OutIOPS) are listed in the I/O assignment for the individual input and output data of the slave. <ul style="list-style-type: none"> Respective byte set to 0x80: Data is valid. Respective bit set to not equal to 0x80: Data is invalid. |

Description

General device information and the entire GSDML file can be read [here](#).

9.23.21 X20IF10G3-1

Data sheet version: 2.18

9.23.21.1 General information

The interface module is equipped with an EtherCAT interface. This allows the B&R system (I/O modules, POWERLINK, etc.) to be connected to systems from other manufacturers and makes it possible to quickly and easily transfer data in both directions.

The interface module can be operated in X20 CPUs or in the expandable POWERLINK bus controller X20BC1083.

The interface is equipped with 2 RJ45 connections. Both connections result in an integrated switch. This makes it easy to implement daisy chain cabling.

- EtherCAT slave
- Integrated switch for efficient cabling

| | | | Off | Status INIT | |
| | | | Single flash | Status SAFE-OPERATIONAL | |
| | | | Blinking | Status PREOPERATIONAL | |
| | ECAT ERR | Red | On | Status OPERATIONAL | |
| | | | Off | No error | |
| | | | Single flash | Internal module error, EtherCAT status changed by module | |
| | | | Double flash | Watchdog timeout (process data watchdog or EtherCAT watchdog) | |
| | L/A IN L/A OUT | Green | Blinking | Invalid configuration data | |
| | | | On | Critical communication or application error | |
| | | | Off | No physical Ethernet connection (PORT CLOSED) | |
| | | | Blinking | The respective LED blinks when Ethernet activity is taking place (PORT OPEN) on the corresponding RJ45 interface (in, out). | |
| | | | On | Connection (link) established, but no communication taking place (PORT OPEN) | |

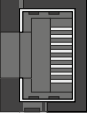

LED status indicators - Blink times

9.23.21.4.2 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see ["Cabling guidelines for X20 modules with an Ethernet cable"](#) on page 58.

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  1 Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.23.21.5 Use in the expandable X20BC1083 POWERLINK bus controller

9.23.21.5.1 Cyclic data

If this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).

When using multiple X20IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

9.23.21.5.2 Operating netX modules

It is important to note the following in order to operate netX modules with the bus controller without problems:

- A minimum revision $\geq E0$ is required for the bus controller.
- netX modules can only be operated with the POWERLINK V2 setting. V1 is not permitted.
- With SDO access to POWERLINK object 0x1011/1 on the bus controller, the netX firmware and the configuration stored on the bus controller are not reset. They can only be overwritten by accessing them again. This affects objects 0x20C0 and 0x20C8, subindexes 92 to 95.

9.23.21.6 netX error codes

netX modules return an error code when an error occurs. These error codes are fieldbus-specific. A complete list of all error codes in PDF format is available in Automation Help in section "Communication / Fieldbus systems / Support with FDT/DTM / Diagnostic functions / Diagnostics on the runtime system / Master diagnostics" under item "Communication_Error".

9.23.21.7 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.21.8 Supported protocols and functions

Supported protocols:

- SDO client-server protocol (CoE object)
- CoE emergency message (CoE object)
- Ethernet over EtherCAT (EoE object)
- File access over EtherCAT (FoE object)
- Complete access (supported since firmware version 18)

Additional supported functions:

- 32-bit "distributed clocks" function

Unsupported functions:

- Reading and writing a logical memory area (LRW)

9.23.21.9 The EtherCAT interface

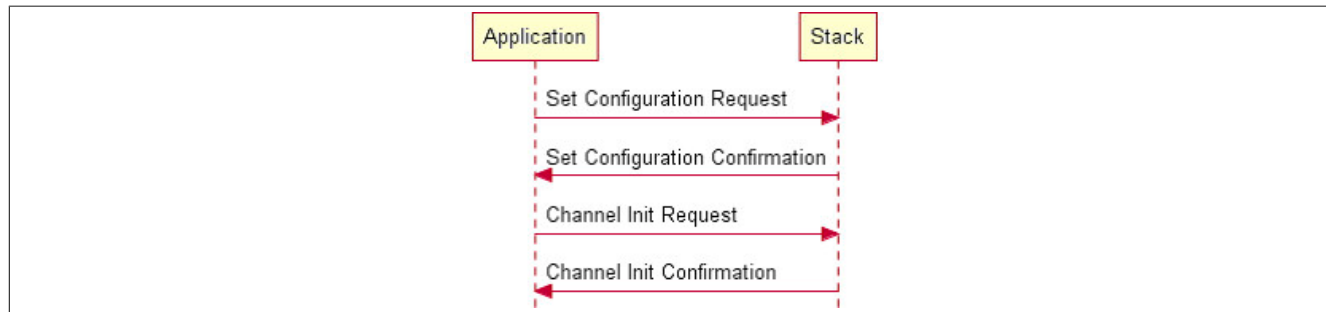

From an Ethernet standpoint, the EtherCAT bus is simply a single large Ethernet station. This "station" receives and transmits Ethernet telegrams. The station does not include an Ethernet controller with downstream microprocessor, however, but rather a large number of EtherCAT slaves. These slaves process the incoming telegrams during the cycle and extract the relevant payload data or add it and then forward the telegram to the next EtherCAT slave. The last EtherCAT slave then returns the now fully processed telegram so that it will be sent back to the master by the first slave as a kind of response telegram. This procedure utilizes the fact that Ethernet deals separately with transfers in separate directions (Tx and Rx lines) and operates in full-duplex mode.

The telegrams are processed in the cycle. While the telegrams are delayed by only a few bits before being forwarded, the slave detects and executes commands that were intended for it. Processing occurs in the hardware and is therefore separate from the slave response times. Each station has an addressable 64 kB memory area that can be written to, read from or simultaneously written to and read from. Multiple EtherCAT commands, which each address individual stations and/or memory areas, can be embedded in one Ethernet telegram.

9.23.21.9.1 Startup sequence

Switching on the power triggers the module initialization phase. These contain basic information such as vendor ID and product code. Then comes channel initialization. The new configurations and parameters are sent to the stack. The stack is then ready to start communicating with the EtherCAT master. The LED "READY/RUN" (see ["LED status indicators" on page 2436](#)) on the interface module indicates any problems during startup by blinking in a certain pattern.

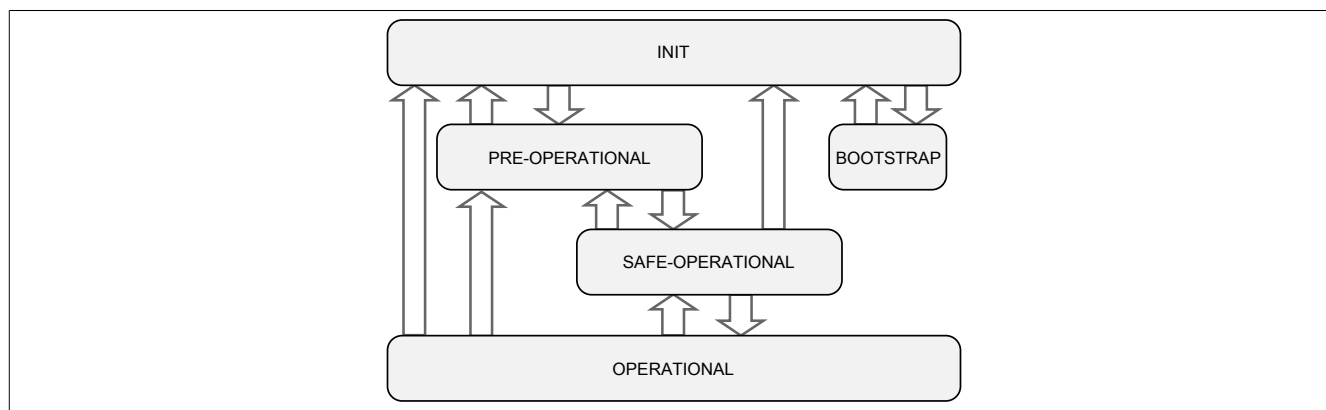

Startup sequence

Operating status

| Status | Description |
|------------------|---|
| INIT | The EtherCAT is being initialized. No process data is being exchanged yet. |
| PREOPERATIONAL | The master and slave are not yet operable but are exchanging parameter data acyclically via the mailbox. No process data is being exchanged yet. |
| SAFE-OPERATIONAL | The EtherCAT slave can process input data. Output data is in status "SAFE" |
| OPERATIONAL | The EtherCAT slave is operational. |
| BOOTSTRAP | Permitted according to EtherCAT specification but not necessary. |

The following diagram shows the possible status changes within the module.

9.23.21.9.2 Object dictionary

The object dictionary is subdivided into different, uniquely defined areas. Detailed information regarding the objects can be found in the EtherCAT specification.

| Index | Area | Description |
|------------------|----------------------|--|
| 0x0000 to 0x0FFF | Data type area | Definition and description of data types |
| 0x1000 to 0x1FFF | Communication area | Definition of generally valid variables (Communication objects for all devices are defined in the CANopen standard DS301) |
| 0x2000 to 0x5FFF | Vendor-specific area | Definition of vendor-specific variables |
| 0x6000 to 0x9FFF | Profile area | Definition of profile-related variables |
| 0xA000 to 0xFFFF | Reserved | Reserved |

9.23.21.9.3 AL status codes

The AL status code reflects the current slave error state. It is located in the ESC register and can be read by the master.

List of standard EtherCAT AL status codes

| Code | Description |
|------------------|---|
| 0x0000 | No error |
| 0x0001 | Unspecified error |
| 0x0011 | Invalid requested state change |
| 0x0012 | Unknown requested state |
| 0x0013 | Bootstrap not supported |
| 0x0014 | No valid firmware |
| 0x0015 | Invalid mailbox configuration (BOOTSTRAP) |
| 0x0016 | Invalid mailbox configuration (PREOP) |
| 0x0017 | Invalid sync manager configuration |
| 0x0018 | No valid inputs available |
| 0x0019 | No valid outputs available |
| 0x001A | Synchronization error |
| 0x001B | Sync manager watchdog |
| 0x001C | Invalid sync manager type |
| 0x001D | Invalid output configuration |
| 0x001E | Invalid input configuration |
| 0x001F | Invalid watchdog configuration |
| 0x0020 | Slave needs cold start |
| 0x0021 | Slave needs "INIT" |
| 0x0022 | Slave needs "PREOP" |
| 0x0023 | Slave needs "SAFEOP" |
| 0x002D | Invalid output "FMMU" configuration |
| 0x002E | Invalid input "FMMU" configuration |
| 0x0030 | Invalid DC "SYNCH" configuration |
| 0x0031 | Invalid DC latch configuration |
| 0x0032 | "PLL" error |
| 0x0033 | Invalid DC I/O error |
| 0x0034 | Invalid DC timeout error |
| 0x0042 | "MBX_EOE" |
| 0x0043 | "MBX_COE" |
| 0x0044 | "MBX_FOE" |
| 0x0045 | "MBX_SOE" |
| 0x004F | "MBX_VOE" |
| 0x0050 to 0x8000 | Reserved |
| 0x800 to 0xFFFF | Vendor-specific |

If the standard EtherCAT error code does not sufficiently describe the current error, then the status error code with an offset of "0x8000" (vendor-specific range) will be written to the "AL status code register".

Supported vendor-specific AL status codes

| Value | AL status code |
|--------|---|
| 0x8000 | ECAT_AL_STATUS_CODE_HOST_NOT_READY |
| 0x8001 | ECAT_AL_STATUS_CODE_IO_DATA_SIZE_NOT_CONFIGURED |
| 0x8002 | ECAT_AL_STATUS_CODE_DPM_HOST_WATCHDOG_TRIGGERED |
| 0x8003 | ECAT_AL_STATUS_CODE_DC_CFG_INVALID |
| 0x8004 | ECAT_AL_STATUS_CODE_FIRMWARE_IS_BOOTING |
| 0x8005 | ECAT_AL_STATUS_CODE_WARMSTART_REQUESTED |
| 0x8006 | ECAT_AL_STATUS_CODE_CHANNEL_INIT_REQUESTED |
| 0x8007 | ECAT_AL_STATUS_CODE_CONFIGURATION_CLEARED |

9.23.21.9.4 Settings in Automation Studio

The interface module can be operated in the slot of a CPU or in the slot of an expandable POWERLINK bus controller.

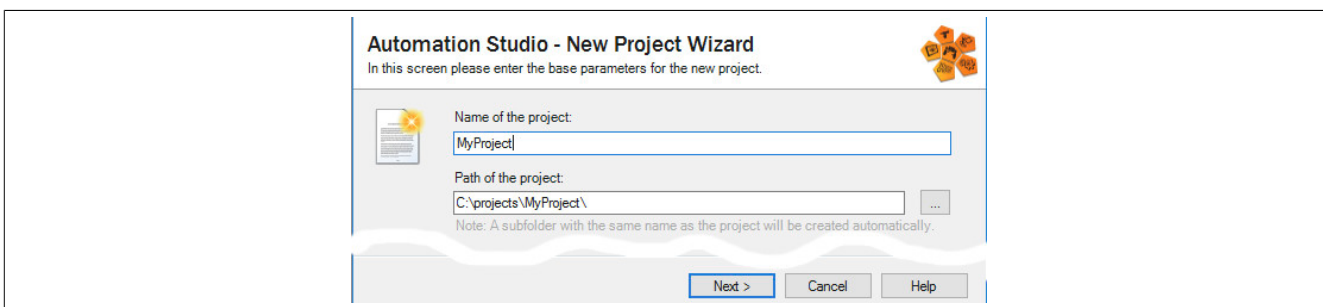

To do this, a new Automation Studio project is created and the suitable settings are made on the module.

9.23.21.9.4.1 Creating an Automation Studio project

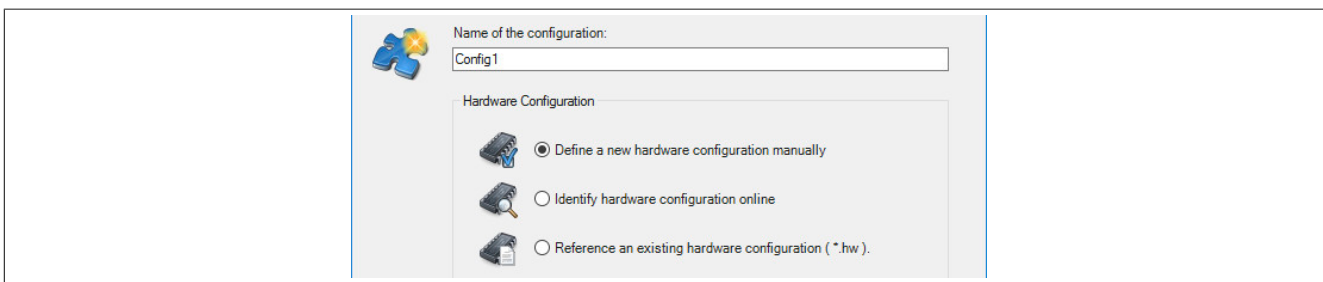

- Create a new Automation Studio project by selecting "New project".

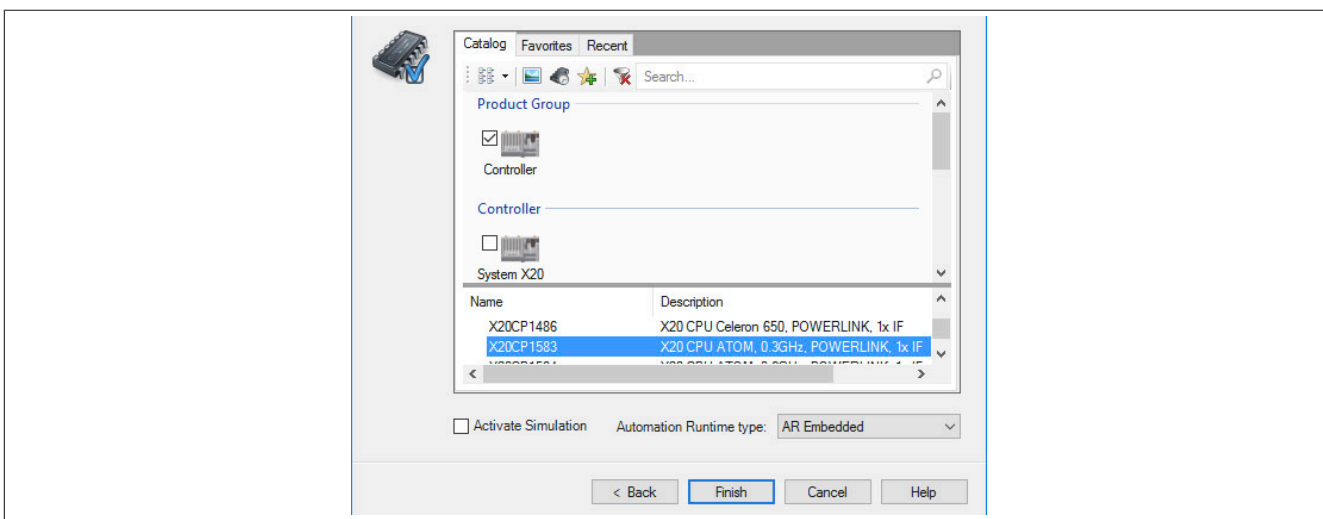

- Assign a project name and set up the project path.

- Assign the hardware configuration type and configuration name.

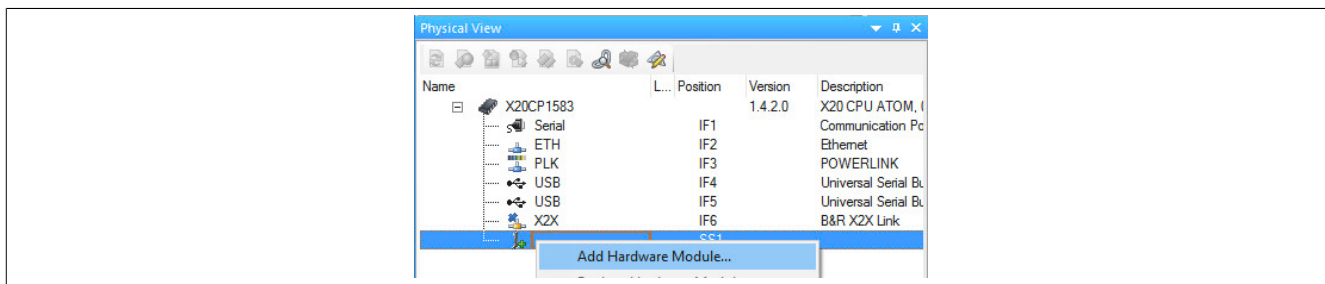

- Select the hardware in the next step if "Define a new hardware configuration manually" was selected. In order to simplify the search, different filters can be set in the Hardware Catalog. Lastly, highlight the required hardware and create the Automation Studio project by clicking on "Finish".

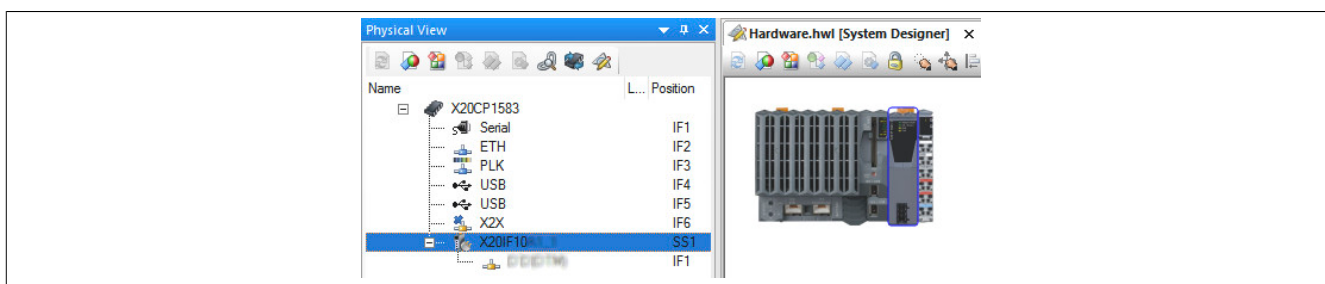

9.23.21.9.4.2 Adding and configuring the interface module

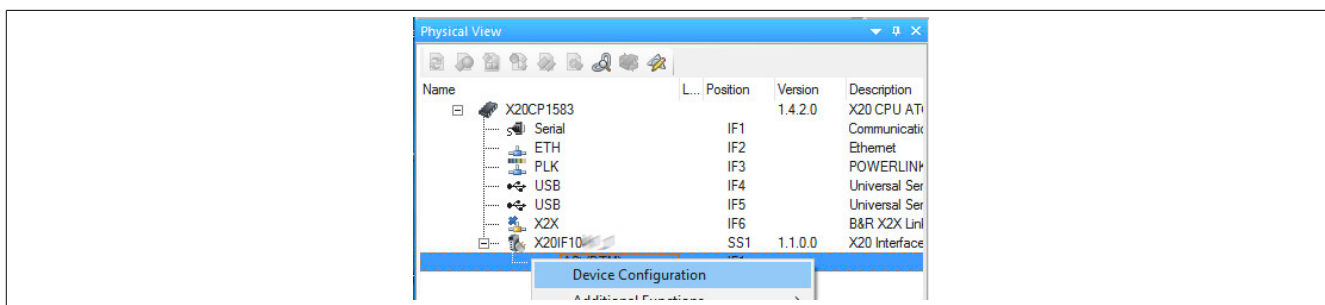

- In this example, the interface card is connected in the slot of a CPU. Right-clicking on the slot and selecting "Add hardware module" opens the Hardware Catalog.

- The module is added to the project via drag-and-drop or by double-clicking on the interface card.

- Additional module settings can be made under "Device configuration". This configuration environment is opened by right-clicking on the IF interface and selecting "Device configuration".

Information:

The settings on the slave must match the settings of the corresponding device description file; otherwise, no connection can be established.

- General settings are made in the device configuration.

General settings

- Bus startup

It is possible to select how data exchange is started on the module.

| Parameter | Explanation |
|---------------------------|--|
| Automatically by device | Data exchange is started automatically after initializing this module. |
| Controlled by application | Data exchange is started by Automation Runtime. |

- Watchdog time

The watchdog is triggered as soon as it receives no feedback after the set "Watchdog time" has expired. In this case, [AL status code 0x8002](#) is output.

| Parameter | Explanation | Values |
|---------------|---|----------------|
| Watchdog time | Watchdog software disabled | 0 ms |
| | Permissible range of values Default value: 1000 ms | 20 to 65535 ms |

Information:

The watchdog time is reset automatically by Automation Runtime.

- Ident

Settings such as the vendor ID or product code can be read out or adjusted here.

| Parameter | Explanation | Default value | Subindex (in object 0x1018) |
|-----------------|--|--|-----------------------------|
| Vendor ID | Manufacturer identification of the EtherCAT device | 0x0000006C (B&R vendor ID) | 1 |
| Product code | Product code of the device | 0xA72C (product code of the X20IF10G3-1) | 2 |
| Revision number | Manufacturer revision number of the device | 0x20000 | 3 |
| Serial number | Serial number of the device | 0 | 4 |

To be able to change the identifier, checkbox "Enable" must be selected.

Information:

Care should be taken when changing the identifier parameters. Problems could arise when establishing a connection since the identifier data is compared in the process. The changed data must also be adjusted on the master side in order to avoid communication errors.

- Data

The length of the input and output data as well as the pulse length can be adjusted.

| Parameter | Explanation | Default value | Maximum value |
|---------------------|--|------------------------------|-------------------|
| Input data bytes | Number of input process data bytes | 200 bytes | 256 bytes |
| Output data bytes | Number of output process data bytes | 200 bytes | 256 bytes |
| Sync impulse length | Length of the synchronization pulse (optional) | 100 (corresponds to 1000 ns) | 65535 (655350 ns) |

Signal configuration

The current signal configuration of the PDOs is displayed here.

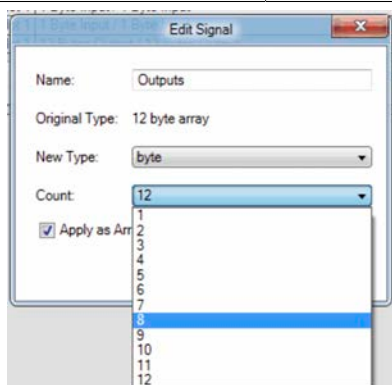

| Parameter | Explanation |
|-----------|----------------------|
| Name | Signal type |
| Type | Data type |
| Offset | Offset of the signal |

After right-clicking on the signal to be configured, the following options can be selected in the shortcut menu:

- **Edit signal**

This allows the currently selected signal to be edited.

| Parameter | Explanation |
|----------------|--|
| Name | The new name for the signal |
| New type | The new data type for the signal |
| Count | Number of individually listed data type elements for the signal. Only the data of the original type is re-structured; the quantity is not adjusted. - The maximum number corresponds to the quantity that the new data type requires to display the original type. - If fewer elements are selected, the last data type element is listed as an array of all remaining elements. |
| Apply as array | If selected, the new data type is displayed as an array. Otherwise, the data type elements set under "Count" are displayed. |

| Slot 4 / Subslot 1 12 Bytes Output / 12 Bytes Output | | |
|--|---------------|--------|
| Name | Type | Offset |
| Outputs | 12 byte array | 0 |
| Outputs_Byte_0 | byte | 0 |
| Outputs_Byte_1 | byte | 1 |
| Outputs_Byte_2 | byte | 2 |
| Outputs_Byte_3 | byte | 3 |
| Outputs_Byte_4 | byte | 4 |
| Outputs_Byte_5 | byte | 5 |
| Outputs_Byte_6 | byte | 6 |
| Outputs_Byte_7 | byte | 7 |
| Outputs_Byte_8 | 4 byte array | 8 |

- **Reset**

This can be used to undo the signal change or a merge previously completed with "Merge signal".

- **Merge signal**

This allows all signals between "First in group" and "Last in group" to be merged to form a new group. The same settings can be made for the new group as under "Edit signal".

XML DDF viewer

The contents of the DDF device description file can be viewed and searched here.

9.23.21.9.5 ESI device description file

The module description is made available to the master in an ESI file. This text file is a general description of the slave. The ESI file can be downloaded from the B&R website (www.br-automation.com) in the Downloads section for the interface module and then imported into the respective master environment.

The device description file defines all necessary sync managers and mailbox parameters.

Mailbox parameter "PdoUpload" is defined with "TRUE". This instructs the EtherCAT master to read all of the process data information via CoE (CANopen over EtherCAT) from the interface card and create a corresponding I/O mapping.

In 3rd-party environments, the interface card is displayed under the name "CIFX RE/ECS".

Sync master

The following entries in the ESI file define the outbox/inbox (required for asynchronous communication between the EtherCAT master and interface card) as well as the properties of the input/output process data (synchronous communication).

```

<!--SM0 MBX OUT-->
<Sm ControlByte="#x36" DefaultSize="128" Enable="1" MaxSize="128" MinSize="128"
  StartAddress="#x1000">MBoxOut</Sm>

<!--SM1 MBX INP-->
<Sm ControlByte="#x32" DefaultSize="128" Enable="1" MaxSize="128" MinSize="128"
  StartAddress="#x1080">MBoxIn</Sm>

<!--SM2 PD OUT-->
<Sm ControlByte="#x74" DefaultSize="200" Enable="1" MaxSize="256" MinSize="0"
  StartAddress="#x1100">Outputs</Sm>

<!--SM3 PD INP-->
<Sm ControlByte="#x30" DefaultSize="200" Enable="1" MaxSize="256" MinSize="0"
  StartAddress="#x1400">Inputs</Sm>

```

Mailbox setting

```

<Mailbox DataLinkLayer="1">
  <CoE CompleteAccess="1"
    PdoUpload="1"
    SdoInfo="1" />
</Mailbox>

```

EEPROM setting

```

<Eeprom>
  <ByteSize>65536</ByteSize>
  <ConfigData>060000CCE8030000</ConfigData>
  <BootStrap>0010800080108000</BootStrap>
</Eeprom>

```

9.23.22 X20(c)IF10X0

Data sheet version: 1.15

9.23.22.1 General information

Interface module for the operation of redundant CPUs.

- CPU-CPU data synchronization module for redundant CPU systems

9.23.22.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.22.5 LED status indicators

| Figure | LED | Color | Status | Description |
|---|-----------------------|------------|--|---------------------------------------|
|  | STATUS ¹⁾ | Green | On | Interface module active |
| | | Red | Blinking | CPU starting up |
| | REDUND ¹⁾ | Green | On | Bumpless switchover of CPU possible |
| | | | Blinking | Minor bump switchover of CPU possible |
| | | | Double flash | Major bump switchover of CPU possible |
| | | Flickering | Application synchronization in progress | |
| | Red | On | Switchover of CPU not possible. It is not differentiated whether it is not possible to switch over only for a short time or whether it is not possible to switch over permanently. | |
| | | Green | On | rCPU = Primary CPU |
| | PRIMARY ¹⁾ | Green | On | rCPU = Primary CPU |
| | | Off | Off | rCPU = Secondary CPU |
| | Red | On | Impermissible operation of the selector switch: One rCPU must be configured as primary, the other as secondary. Modifying the switch position during operation is not permitted. | |
| | | Green | On | rCPU actively controlling the process |
| | ACTIVE | Green | On | rCPU actively controlling the process |
| | | Off | Off | rCPU inactive |
| LA/IF ¹⁾ | Green | On | Connection established to redundancy partner | |
| | | Blinking | Redundancy link active. Data traffic is taking place for synchronization purposes. | |
| | Red | On | No connection to redundancy partner | |

1) This LED is a green/red dual LED.

LEDs - Blink times

9.23.22.6 Operating and connection elements

9.23.22.7 Switch positions

The CPU can be set to primary or secondary using the "PRIM/SEC" selection switch.

During configuration, make sure that one rCPU is set as primary and the other rCPU as secondary.

Information:

It is not permitted to change the switch position during operation.

The "T" button is used for redundancy switchovers and manually synchronizing the application.

9.23.22.8 Derating

The temperatures listed in the technical data are valid when the unit is operated in the left IF slot of the X20CP358x CPUs.

When operated in the IF slot of the X20CP158x CPUs, the maximum temperature values are reduced by 5°C

9.23.22.9 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.23 X20(c)IF2181-2

Data sheet version: 1.15

9.23.23.1 General information

The interface module is used to expand the X20 CPU for specific applications. It is equipped with an POWERLINK interface.

POWERLINK is a standard protocol for Fast Ethernet equipped with hard real-time characteristics. The POWERLINK Standardization Group (EPSG, see www.ethernet-powerlink.org) ensures its openness and continual development.

Systems with redundant cabling can be implemented easily using POWERLINK. Unlike ring redundancy, cable redundancy does not require cable looping, which can sometimes be problematic. This allows the creation of all types of tree structures. When using a device with the link selector function, data is always transferred via the highest quality network lines. The link selector function is integrated in the X20IF2181-2 module.

- POWERLINK V2 for real-time Ethernet communication
- Integrated link selector function (preconfigured)
- Redundant Managing Node for controller redundancy
- Integrated hub for efficient cabling (configurable)
- Configurable ring redundancy
- Poll response chaining
- Dynamic Node Allocation (DNA)

9.23.23.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.23.23.5 LED status indicators

| Figure | LED | Color | Status | Description |
|--|-----------|-----------|----------|---|
|  | S/E | Green/Red | | Status/Error-LED. Die LED-Status sind im Abschnitt LED "S/E" beschrieben. |
| | RS | Green | On | Both cable connections are OK. |
| | | Red | On | At least one cable connection is faulty. |
| | L/A X1/X2 | Green | On | A link to the POWERLINK remote station has been established. |
| | | | Blinking | A link to the POWERLINK remote station has been established. Indicates Ethernet activity is taking place on the bus |

LED "S/E"

This LED is a green/red dual LED and indicates the state of the POWERLINK interface. The LED states have a different meaning depending on the operating mode of the POWERLINK interface.

Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

| Farbe grün - Status | Beschreibung |
|---------------------|--|
| Ein | Die Schnittstelle wird als Ethernet-Schnittstelle betrieben. |

POWERLINK mode

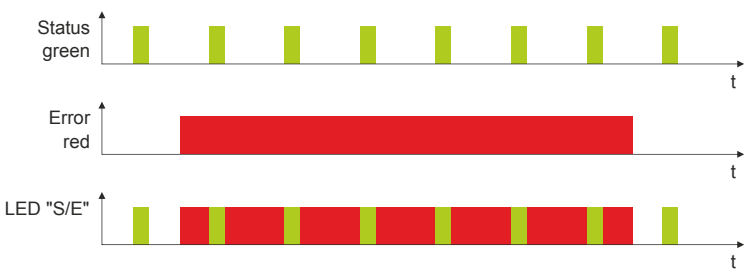

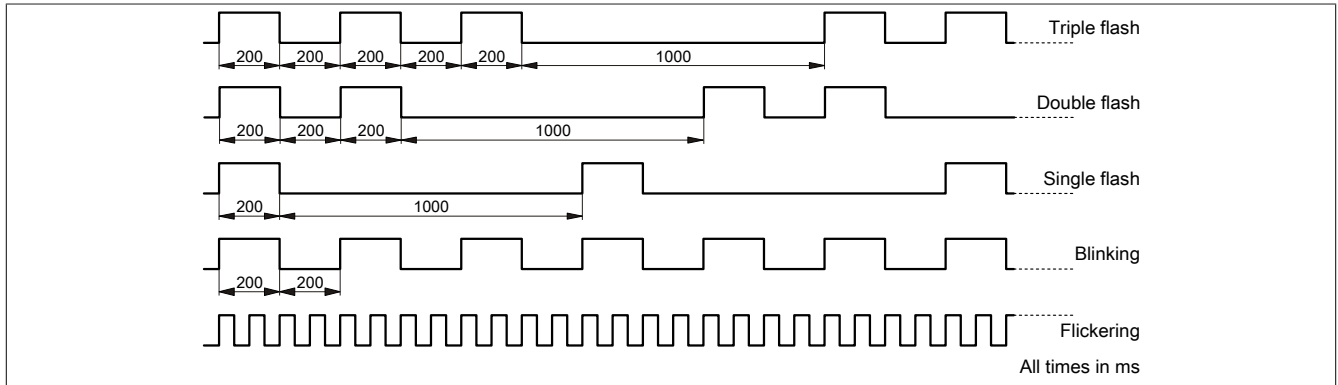

| Red - Error | Description |
|-------------|--|
| On | <p>The module is in an error mode (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED:</p> <ul style="list-style-type: none"> PRE_OPERATIONAL_1 PRE_OPERATIONAL_2 READY_TO_OPERATE  <p>Note: The LED blinks red several times immediately after startup. This is not an error, however.</p> |

Table 468: Status/Error LED as Error LED

| Farbe grün - Status | Beschreibung |
|------------------------------------|---|
| Aus | <p>Modus Das Modul befindet sich im Modus NOT_ACTIVE oder es ist:</p> <ul style="list-style-type: none"> • ausgeschaltet • im Hochlauf • in Automation Studio nicht richtig konfiguriert • defekt <p>Managing Node (MN) Der Bus wird auf POWERLINK-Frames überwacht. Wird in dem eingestellten Zeitfenster (Timeout) kein entsprechender Frame empfangen, geht das Modul direkt in den Modus PRE_OPERATIONAL_1 über. Wenn jedoch vor Ablauf der Zeit eine POWERLINK-Kommunikation erkannt wird, wird der MN nicht gestartet.</p> <p>Controlled Node (CN) Der Bus wird auf POWERLINK-Frames überwacht. Wird in dem eingestellten Zeitfenster (Timeout) kein entsprechender Frame empfangen, geht das Modul direkt in den Modus BASIC_ETHERNET über. Wenn jedoch vor Ablauf der Zeit eine POWERLINK-Kommunikation erkannt wird, geht das Modul direkt in den Modus PRE_OPERATIONAL_1 über.</p> |
| Grün flackernd (ca. 10 Hz) | <p>Modus Das Modul befindet sich im Modus BASIC_ETHERNET. Die Schnittstelle wird als Ethernet-TCP/IP-Schnittstelle betrieben.</p> <p>Managing Node (MN) Dieser Zustand kann nur durch einen Reset des Moduls verlassen werden.</p> <p>Controlled Node (CN) Wird während dieses Zustandes eine POWERLINK-Kommunikation erkannt, geht das Modul in den Zustand PRE_OPERATIONAL_1 über.</p> |
| Single Flash (ca. 1 Hz) | <p>Modus Das Modul befindet sich im Modus PRE_OPERATIONAL_1.</p> <p>Managing Node (MN) Der MN startet den Betrieb des "reduced cycles". Es findet noch keine zyklische Kommunikation statt.</p> <p>Controlled Node (CN) In diesem Zustand kann das Modul vom MN konfiguriert werden. Der CN wartet auf den Empfang eines SoC Frames und wechselt dann in den Zustand PRE_OPERATIONAL_2. Wenn in diesem Zustand die rote LED leuchtet, heißt das, dass der MN ausgefallen ist.</p> |
| Single Flash (ca. 1 Hz) Invertiert | <p>Modus Das Modul befindet sich im Modus STANDBY.</p> <p>Dieser Zustand ist nur im Controller-Redundanz Mode möglich. Der POWERLINK Manager wird gerade als Standby Managing Node (SMN) betrieben.</p> |
| Double Flash (ca. 1 Hz) | <p>Modus Das Modul befindet sich im Modus PRE_OPERATIONAL_2.</p> <p>Managing Node (MN) Der MN beginnt mit der zyklischen Kommunikation (zyklische Eingangsdaten werden noch nicht ausgewertet). In diesem Zustand werden die CNs konfiguriert.</p> <p>Controlled Node (CN) In diesem Zustand kann das Modul vom MN konfiguriert werden. Danach wird per Kommando in den Zustand READY_TO_OPERATE weitergeschaltet. Wenn in diesem Modus die rote LED leuchtet, heißt das, dass der MN ausgefallen ist.</p> |
| Triple Flash (ca. 1 Hz) | <p>Modus Das Modul befindet sich im Zustand READY_TO_OPERATE.</p> <p>Managing Node (MN) Zyklische und asynchrone Kommunikation. Die empfangenen PDO-Daten werden ignoriert.</p> <p>Controlled Node (CN) Die Konfiguration des Moduls ist abgeschlossen. Normale zyklische und asynchrone Kommunikation. Die gesendeten PDO Daten entsprechen dem PDO-Mapping. Zyklische Daten werden jedoch noch nicht ausgewertet. Wenn in diesem Modus die rote LED leuchtet, heißt das, dass der MN ausgefallen ist.</p> |
| Ein | <p>Modus Das Modul befindet sich im Modus OPERATIONAL. PDO-Mapping ist aktiv und zyklische Daten werden ausgewertet.</p> |
| Blinkend (ca. 2,5 Hz) | <p>Modus Das Modul befindet sich im Modus STOPPED.</p> <p>Managing Node (MN) Dieser Zustand ist im MN nicht möglich.</p> <p>Controlled Node (CN) Ausgangsdaten werden nicht ausgegeben und es werden keine Eingangsdaten geliefert. Dieser Modus kann nur durch ein entsprechendes Kommando vom MN erreicht und wieder verlassen werden.</p> |

Table 469: Status/Error-LED als Status-LED - Betriebsmodus POWERLINK

LED status indicators - Blinking patterns

9.23.23.5.1 System stop error codes

A system stop error can occur due to incorrect configuration or defective hardware.

The error code is indicated by LED "S/E" blinking red. The blinking signal of the error code consists of 4 switch-on phases with short (150 ms) or long (600 ms) duration. The error code is repeated every 2 seconds.

| Error | Error description |
|----------------|---|
| RAM error | The device is defective and must be replaced. |
| Hardware error | The device or a system component is defective and must be replaced. |

9.23.23.6 Operating and connection elements

9.23.23.7 POWERLINK node number

The node number for the POWERLINK station is set using the two number switches. The node number can also be directly configured using Automation Studio.

9.23.23.7.1 POWERLINK V2

| Switch position | Description |
|-----------------|---|
| 0x00 | Reserved, switch position not permitted. |
| 0x01 - 0xEF | Node number of POWERLINK station. Operation as controlled node. |
| 0xF0 | Operation as managing node. |
| 0xF1 - 0xF7 | Reserved, switch position not permitted. |
| 0xF8 | Controller redundancy: Function as primary CPU |
| 0xF9 | Controller redundancy: Function as secondary CPU |
| 0xFA - 0xFF | Reserved, switch position not permitted. |

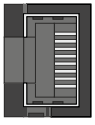

9.23.23.7.2 Ethernet mode

In this mode, the interface is operated as an Ethernet interface. The INA2000 station number is set using the B&R Automation Studio software.

9.23.23.8 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see "Cabling guidelines for X20 modules with an Ethernet cable" on page 58.

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.23.23.9 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.23.10 POWERLINK cable redundancy system

It is often indispensable to have redundant network cabling, especially in systems that handle technical processes. The potential for danger, especially to the lines that run through the system, is disproportionately high in relation to the need to keep communication active in all operating situations. This risk is effectively reduced with double cabling that is routed separately.

The POWERLINK cable redundancy system is based on the principle of doubling the transfer routing as well as providing continual and simultaneous monitoring. That means data is simultaneously fed into two cable lines using a corresponding mechanism. The same mechanisms are used to receive these telegrams from the redundant network.

Information:

Details about the structure of a redundancy system can be found in the "Redundancy for control systems" user's manual. The user's manual is available in the Downloads section of the B&R website www.br-automation.com.

9.23.24 X20IF2772

Data sheet version: 2.23

9.23.24.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with 2 CAN bus interfaces.

- Dual CAN bus connection
- Integrated terminating resistors

Information:

This module does not support CAN RTR messages with extended CAN identifiers (29-bit) (memory/performance bottleneck).

| | TxD CAN 2 | Yellow | On | The module is sending data via the CAN bus interface (IF2) |
| | TERM CAN 1 | Yellow | On | The integrated terminating resistor for the CAN bus interface (IF1) is turned on |
| | TERM CAN 2 | Yellow | On | The integrated terminating resistor for the CAN bus interface (IF2) is turned on |

9.23.24.5 Operating and connection elements

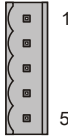

9.23.24.6 CAN bus node number

The node number for the CAN bus interfaces is set with the two hex switches.

9.23.24.7 Interfaces CAN bus 1 and CAN bus 2 (IF1 and IF2)

Both interfaces feature a 5-pin multipoint plug. The OTB2105 terminal block must be ordered separately.

| Interface | Pinout | | |
|--|----------|------------------|------------|
| | Terminal | Function | |
|  5-pin male multipoint connector | 1 | CAN _⊥ | CAN ground |
| | 2 | CAN _L | CAN low |
| | 3 | SHLD | Shield |
| | 4 | CAN _H | CAN high |
| | 5 | NC | |

9.23.24.8 Terminating resistor

Two terminating resistors are integrated in the interface module. The respective resistor can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM CAN 1" or "TERM CAN 2".

9.23.24.9 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.23.25 X20IF2792

Data sheet version: 2.24

9.23.25.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with both an X2X Link interface and a CAN bus interface.

- X2X Link connection
- CAN bus connection
- Integrated terminating resistor

Information:

This module does not support CAN RTR messages with extended CAN identifiers (29-bit) (memory/performance bottleneck).

9.23.25.2 Order data

| Model number | Short description | Figure |

| | 2 | X2X _L | |
| | 3 | X2X _I | |
| | 4 | SHLD | Shield |

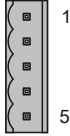

9.23.25.7 CAN bus node number

The node number for the CAN bus interface (IF2) is set with the two hex switches.

9.23.25.8 CAN bus interface

The interface is a 5-pin multipoint connector. Terminal block 0TB2105 must be ordered separately.

| Interface | | Pinout | | |
|--|---|----------|------------------|------------|
|  5-pin male multipoint connector | 1 | Terminal | Function | |
| | | 1 | CAN _L | CAN ground |
| | | 2 | CAN _L | CAN low |
| | | 3 | SHLD | Shield |
| | | 4 | CAN _H | CAN high |
| | | 5 | NC | |

9.23.25.9 Terminating resistor

The interface module has an integrated terminating resistor for the CAN bus interface. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

9.23.25.10 Firmware

The module comes with preinstalled firmware. The firmware is part of Automation Studio. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

9.24 Hub system

The X20HB8880 hub is a device that can be used universally in standard Ethernet networks or POWERLINK networks. It is suitable for 100 Mbit/s (Fast Ethernet) networks. Due to its modular structure, the hub can be configured as 2/4/6x Fast Ethernet hub as needed.

The X20BC8083 bus controller makes it possible to connect X2X Link I/O nodes to POWERLINK. The bus modules expanded to the left allow connection of up to 2 hub expansion modules in addition to the bus controller. This means that a 2/4/6x Fast Ethernet hub is also available on the bus controller depending on the degree of expansion.

9.24.1 Summary

| Model number | Short description | Page |
|--------------|--|------|
| X20ET8819 | X20 Ethernet analysis tool, can be expanded with active hub modules, 2x RJ45 | 2468 |
| X20HB8815 | X20 POWERLINK - TCP/IP gateway, can be expanded with active hub modules, 2x RJ45 | 2480 |
| X20HB8880 | X20 base hub module, integrated 2-port hub, 2x RJ45 | 2490 |
| X20cHB8815 | X20 POWERLINK - TCP/IP gateway, coated, can be expanded with active hub modules, 2x RJ45 | 2480 |
| X20cHB8880 | X20 base hub module, coated, integrated 2-port hub, 2x RJ45 | 2490 |

9.24.2 X20ET8819

Data sheet version: 1.07

9.24.2.1 General information

Analyzing POWERLINK

POWERLINK has proven itself in the field for years and rarely has problems during commissioning and production. Nonetheless, it is still possible for communication disturbances to occur due to damaged or poor quality cables. If an error occurs, localizing and correcting it is usually very easy thanks to the heterogeneous structure of this flat network type (all data is always visible throughout the network). What's problematic are errors that occur sporadically. This is where tools such as Omnippeek or Wireshark come in.

These tools (or more likely the standard PC technology being used) reach their limits, however, when dealing with machines that have short network cycles. Either not all frames can be recorded, or some telegrams are lost altogether. In these cases, what's needed is a special hardware tool that can work very quickly, record and save every bit of traffic and then pass it on to a laptop.

Ethernet analysis tool X20ET8819

This module provides different operating modes. For example, it can work passively on the network, in which case the real-time behavior remains unchanged. The device listens in and selectively takes in data when certain defined trigger conditions are met. It can read all of the data, mark it with a timestamp, store it temporarily and ultimately pass it on to a PC. The data is then analyzed in the familiar PC environment.

- NetTime time stamp has a resolution of 20 ns
- Recording and analysis of CRC and frame errors
- Triggers can also be activated using external digital signals
- Analysis of both half-duplex and full-duplex networks
- Able to record two networks simultaneously

9.24.2.2 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | X20 hub system |  |
| X20ET8819 | X20 Ethernet analysis tool, can be expanded with active hub modules, 2x RJ45 | |

| Spacing ¹⁾ | |
| X20BB80 | 37.5 ^{+0.2} mm |
| X20BB81 | 62.5 ^{+0.2} mm |
| X20BB82 | 87.5 ^{+0.2} mm |

Table 475: X20ET8819 - Technical data

- 1) Spacing is based on the width of the X20BB80 bus base. Up to two X20HB2880 or X20HB2881 hub expansion modules and one X20PS9400 power supply module are also always required for the Ethernet analysis tool.

9.24.2.4 LED status indicators

| Figure | LED | Color | Status | Description |
|---|-------------------|-----------|----------|---|
|  | S/E ¹⁾ | Green/red | | Status/Error LED. The statuses of this LED are described in section "S/E LED" on page 2470. |
| | L/A IF1 | Green | On | A link to the remote station has been established. |
| | | | Blinking | A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus |
| | L/A IF2 | Green | On | A link to the remote station has been established. |
| | | | Blinking | A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus |

1) The Status/Error LED is a green/red dual LED.

9.24.2.5 S/E LED

The Status/Error LED is a green and red dual LED.

| Red - Error | Description |
|-------------|--|
| On | This error can occur only in Analysis mode. If packets are lost when in Analysis mode, the red Status LED lights up. Remedy: Use the "MODE" switch to reduce the number of bytes in the received packets (see "Analysis mode" on page 2476). As soon as no packets are lost for longer than 1 s, it switches back to green. |

Table 476: Status/error LED is red: LED indicates error

| Green - Status | Description |
|----------------------------------|--|
| Off | The Ethernet analysis tool is either booting or not receiving power. |
| Green flickering (approx. 10 Hz) | The analysis tool is in Service mode: Analysis tool disabled, go to website to update firmware (see "Firmware update" on page 2475) |
| Single flash (approx. 1 Hz) | The external trigger is active. No data is currently being recorded. No data has been recorded since turned on. |
| Double flash (approx. 1 Hz) | The external trigger is active. No data is currently being recorded. However, the analysis tool has recorded data at least once. This means that the trigger has been triggered at least once. |
| On | The analysis tool is active, and is recording all received packets. |

Table 477: Status/error LED is green: LED indicates operation

System failure error codes

Incorrect node number or defective hardware can cause a system failure error. The error code is indicated by the red error LED using four switch-on phases. The switch-on phases have a duration of either 150 ms or 600 ms. Error code output is repeated cyclically after 2 seconds.

Key:

- ... 150 ms
- ... 600 ms
- Pause ... 2 sec. delay

| Error description | Error code indicated by red status LED | | | | | | | | | |
|---|--|---|---|---|-------|---|---|---|---|-------|
| RAM error: The module is defective and must be replaced. | • | • | • | – | Pause | • | • | • | – | Pause |
| Wrong node number | • | – | – | – | Pause | • | – | – | – | Pause |
| Hardware errors: The module or a system component is defective and must be replaced. | – | • | • | – | Pause | – | • | • | – | Pause |

Table 478: Status/Error LED as Error LED - System failure error codes

9.24.2.6 Operating and connection elements

9.24.2.7 Operating mode and address switch

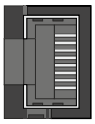

| switches | Description |
|----------|---|
| MODE | Specifies the mode in which the analysis tool is run (see "Analysis mode" on page 2476) |
| ADD | The following addresses are derived from the position of the ADD switch: <ul style="list-style-type: none"> • Own IP address (192.168.0.ADD) • Analysis mode: Destination MAC (01:00:5 e: 00:00: ADD) • Analysis mode: MulticastIP 239.0.0.ADD Note: Position 0 is not permitted |

9.24.2.8 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see "Cabling guidelines for X20 modules with an Ethernet cable" on page 58.

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.24.2.9 Hardware configuration 1

If the Ethernet analysis tool is run without additional hub expansion modules, then recording is only possible on port T0. The analysis tool must be connected to an available hub port in the system.

Information:

An X20HB288x module is not permitted in this hardware configuration.

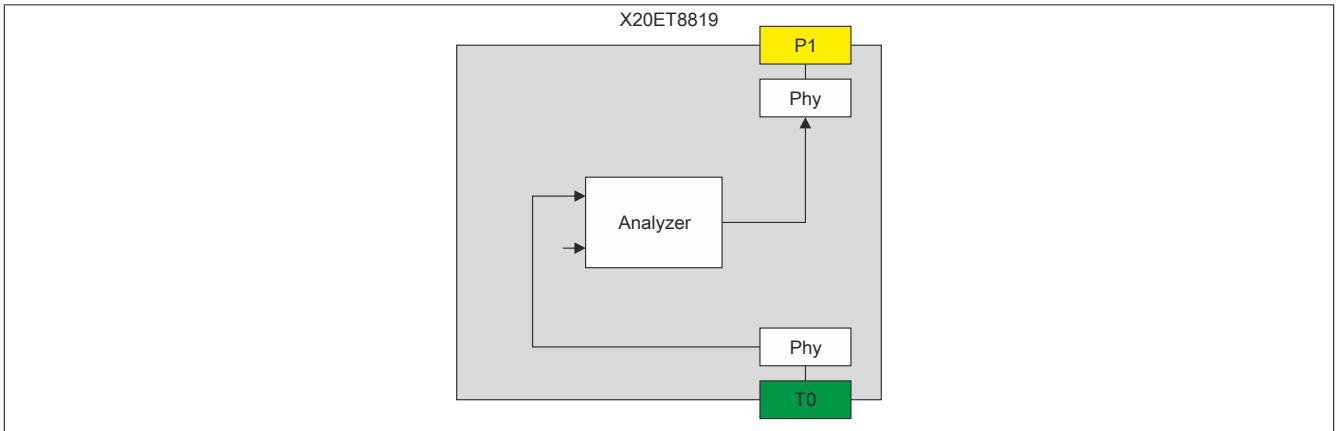

Figure 162: Diagram of hardware configuration 1

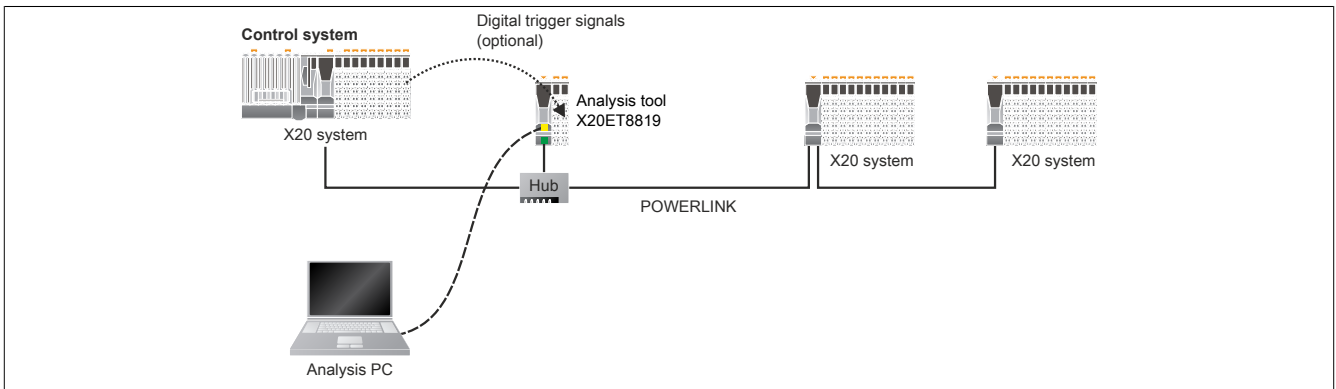

Figure 163: Example application of hardware configuration 1

9.24.2.10 Hardware configuration 2

Extending the Ethernet analysis tool with an X20HB2880 or X20HB2881 allows even full-duplex lines to be recorded as well. In this case ports T1 and T2 are analyzed.

Information:

Only the required X20HB288x module is permitted in this hardware configuration. A second X20HB288x module would produce different behavior (see Hardware configuration 3).

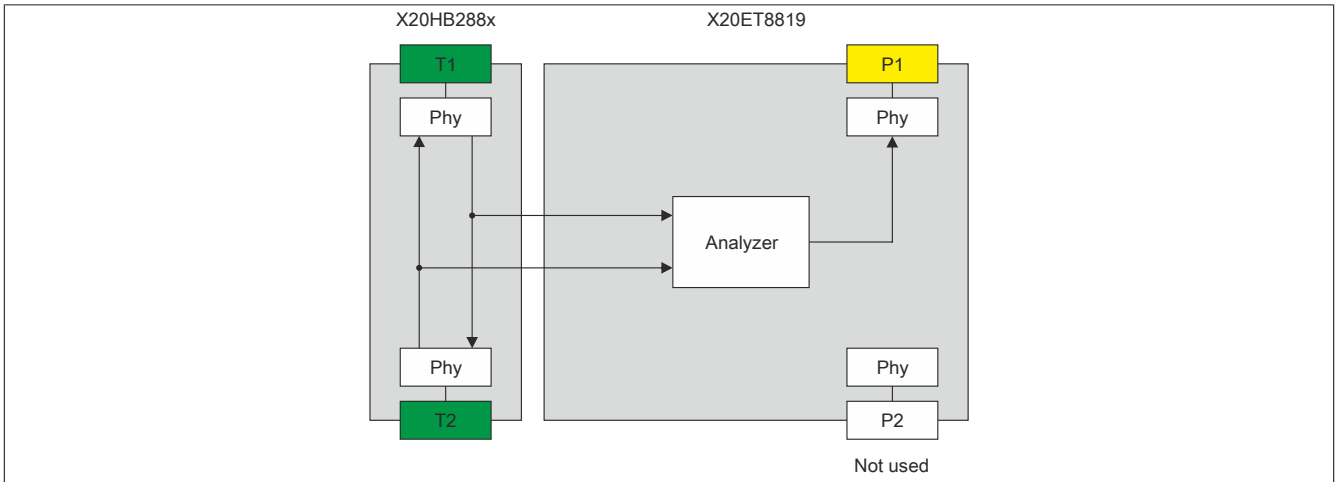

Figure 164: Diagram of hardware configuration 2

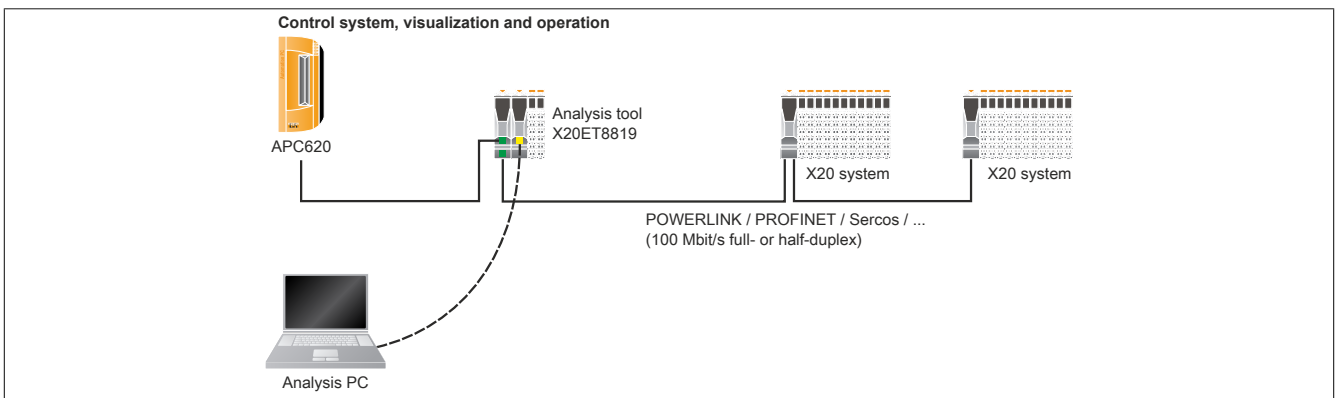

Figure 165: Example application of hardware configuration 2

9.24.2.11 Hardware configuration 3a

Simultaneous data recording at two locations in the network is possible by using two X20HB2880 or X20HB2881. **Only** data from T1 and T3 is analyzed.

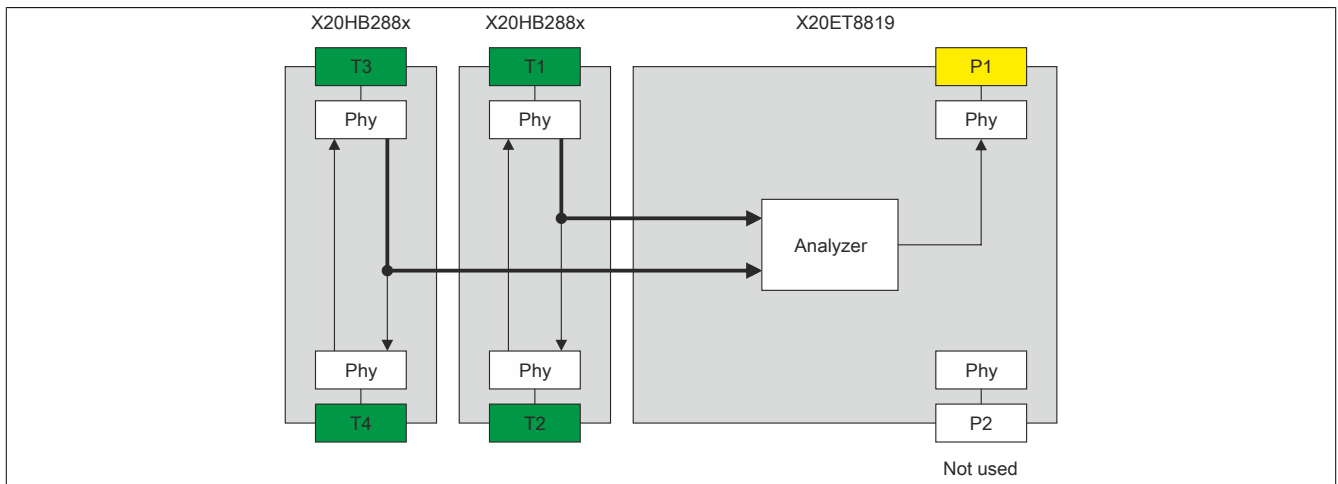

Figure 166: Diagram of hardware configuration 3a

Example application 1 shows data being recorded simultaneously from two hubs.

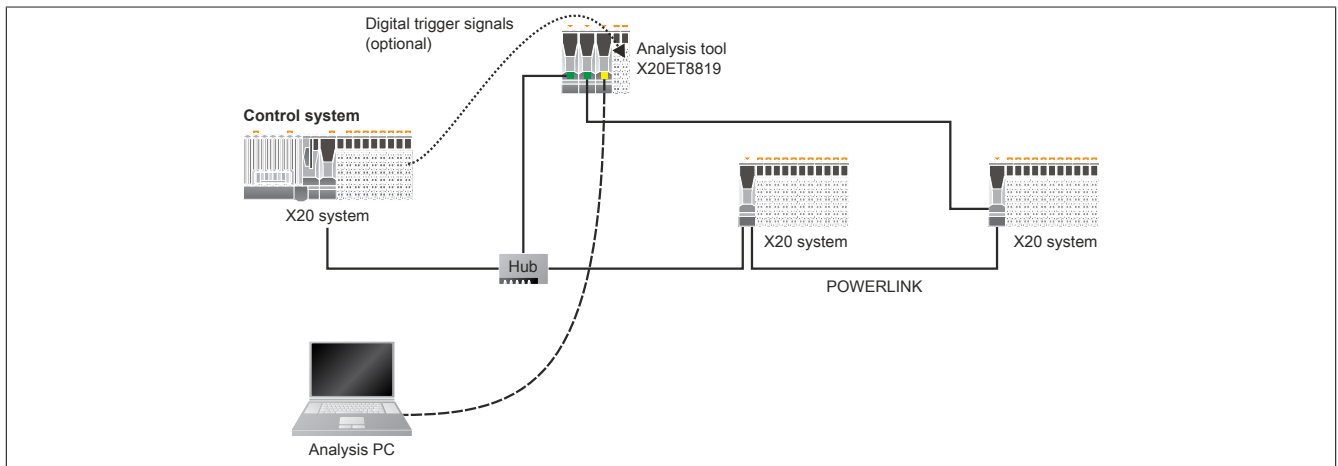

Figure 167: Example application 1 of hardware configuration 3, connection via hubs

The two hub expansion modules can also be inserted in series in the network. It should be noted that in this case data recording is only possible in one direction at a time.

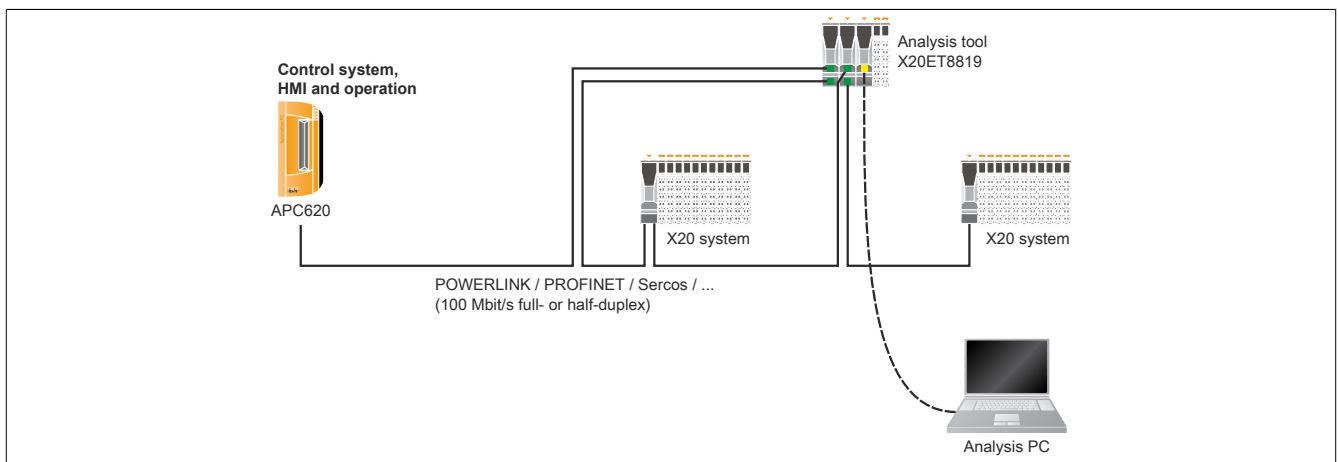

Figure 168: Example application 2 of hardware configuration 3, connection in line

9.24.2.12 Hardware configuration 3b

With firmware V 1.03 and higher, data traffic in half-duplex networks (e.g. POWERLINK) is recorded in both directions.

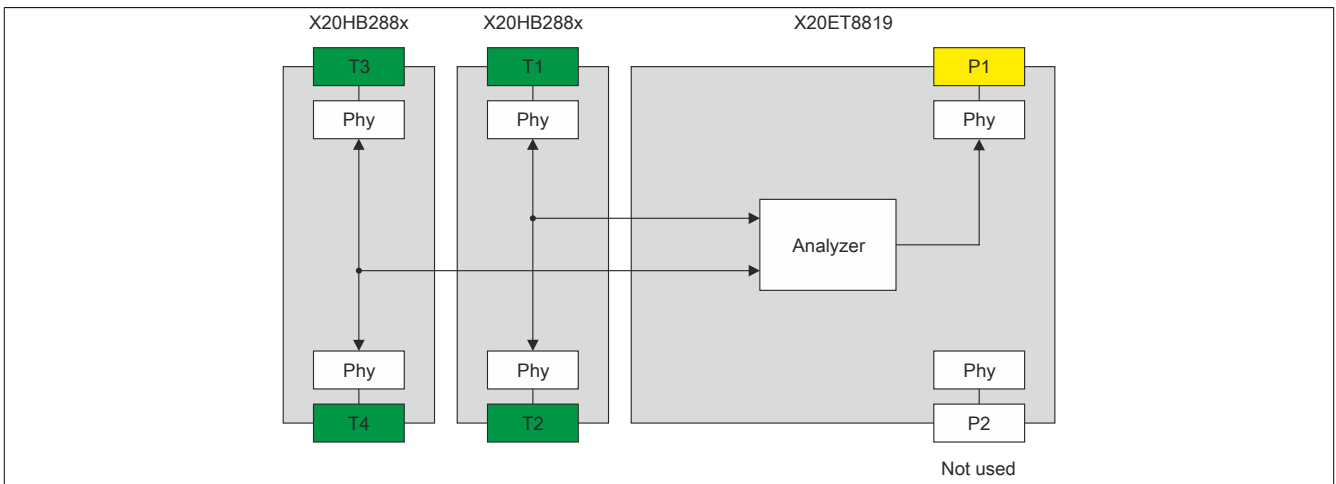

Figure 169: Diagram of hardware configuration 3b

9.24.2.13 Firmware update

To update the firmware, the webpage of the X20ET8819 module must be opened when in service mode. To do this, set the MODE switch to 0 and ADD to a value between 0x1 and 0xF. When the hardware is restarted now, the module will enter service mode. A connection can be established to the webpage using a web browser via the interface IF1 (P1) and the IP address 192.168.0.ADD. The update is started by selecting "Firmware Download".

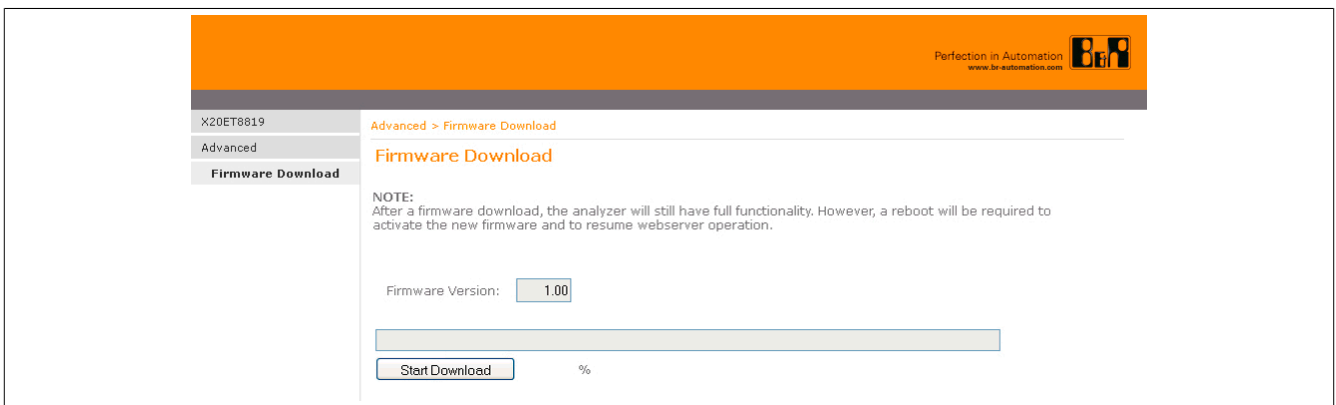

Figure 170: Start firmware update

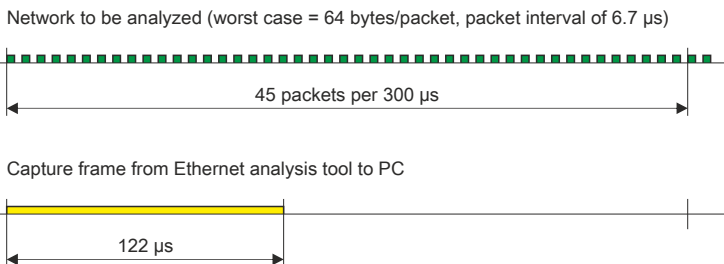

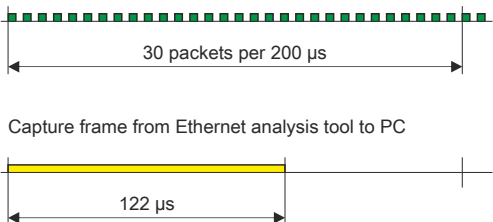

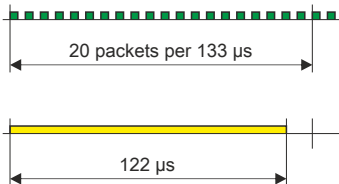

9.24.2.13.1 Firmware history

| Version | Comment |
|---------|---|
| 1.05 | Continuous product improvement for analysis mode A with frame lengths >1016 bytes. |
| 1.04 | <ul style="list-style-type: none"> New analysis mode: In this mode, every package is recorded in its original size. If two X20HB288x modules are used, data traffic on half-duplex networks can be recorded in both directions. |
| 1.02 | Support for trigger outputs: The X20DO9322 can now be used as the second I/O module. |
| 1.00 | First version |

9.24.2.14 Analysis mode

Each time an incoming packet is analyzed, (see hardware configurations 1 to 3), the analysis tool saves the reception timestamp, various flags and the first 'n' bytes of data from the received packet in capture frames. These frames are sent via IF 1 (P1).

The number of recorded data bytes, 'n', is set with the operating mode switch MODE. This defines the number of packets that are sent for each capture frame.

| MODE | n | p/s | Description |
|-------|------------|--------|---|
| 0 | - | - | Service mode |
| 1 | 24 | 148800 | <p>45 packets fit in a capture frame: $(1514-64) / (24+8) = 45$ packets</p>  |
| 2 | 40 | 148800 |  |
| 3 | 64 | 148800 | <p>This is the first setting at which complete packets fit in the capture frame (minimum packet with 60 byte payload). 20 packets can fit in one capture frame, however this setting could cause problems on the analysis PC because there is not much idle time between the capture frames.</p>  |
| 4 | 80 | 128000 | |
| 5 | 120 | 88000 | |
| 6 | 196 | 56000 | |
| 7 | 280 | 40000 | |
| 8 | 716 | 16000 | <p>2 packets fit in a capture frame: $(716+8)*2 + 64 = 1512$ bytes A setting 'n' > 716 has the disadvantage that a network with full capacity would not be able to be analyzed.</p> |
| 9 | 24 to 1440 | - | The analysis tool selects the largest possible value for 'n' itself due to the packet volume of the last capture frame that was sent. This means that each capture frame can be assigned a different 'n' value. 'n' is always a multiple of 4 and can assume values between 24 and 1440. |
| A | - | - | Up to a size of 1440 bytes every packet is recorded in its original size. |
| B - F | - | - | Reserved |

Note:

- A change in the position of the MODE switch from 1 to A will be applied online during operation.
- If the "S/E" LED is red, then the number of bytes to be recorded should be reduced.

9.24.2.15 Using trigger inputs

The Ethernet analysis tool launches the first connected I/O module in the standard function model. The X2X link is configured with a fixed cycle of 1 ms. If this configuration contains digital input data (digital input module X20DI9371), the first 4 digital inputs will be included in the packet header.

9.24.2.15.1 Background

When looking for very complicated errors, it is usually not possible to find a trigger condition on the network. It is often difficult to discern whether the cause of the problem is even associated with the Ethernet communication or somewhere else. The fact that such errors are extremely rare makes finding them that much harder.

A permanent record of network frames through the module X20ET8819 would exceed storage capabilities of the recording software due to the large amount of data. The trigger inputs on the X20ET8819 offer an additional way to circumvent this problem. Analysis of the network can be started or stopped when a specific event occurs.

In most cases, the problem can be indicated using a digital signal. The CPU can detect errors or irregularities (e.g. failure of a network slave), for example, and then set a digital output on the local I/O bus. If this signal is connected to a digital input on the Ethernet analysis tool, then the module is able to evaluate this information and trigger a response such as pausing an active recording.

9.24.2.15.2 Evaluation of the inputs on the analysis tool X20ET8819

Input 1 - 4

The first 4 inputs will be inserted only in the packet header by the X20ET8819. The recording software from B&R (OmniPeek full version and plugin) can determine how the signals are interpreted.

Input 5 - 7

If the recording software is unable to evaluate the first 4 inputs (Wireshark, OmniPeek, various other capture tools), then inputs 5 - 7 are used to control the Ethernet analysis tool X20ET8819 directly.

| Input | Name | Description |
|--------|----------------|--|
| 5 | ExternActivate | Recording will not start automatically if this input is set to HIGH when the analysis tool is turned on. The module waits for a positive edge on input 6. |
| 6 | ExternStart | Recording begins when a positive edge occurs on this input. The value in 'captureId', offset 49 in the capture frame header is incremented to indicate to the receiving tool that a new recording has been started. When recording using the recording software from B&R, this information can be used to switch to a new ring buffer and to store the last one. |
| 7 | ExternStop | Recording stops when a negative edge occurs on this input. |
| 8 - 12 | - | Reserved |

Table 479: Evaluation of inputs 5 - 7 on the analysis tool

Example 1

A drive is started one time each minute. After 10 to 30 hours, a problem arises on a network station shortly after starting the drive. To analyze the error, the Ethernet communication is recorded between when the start command is issued and when the error occurs.

Problems:

Due to the large amount of data it is not possible to record the entire 30 hours. Someone would have to stay on the analysis PC the whole time to stop recording when the error occurs.

Solution:

| Input | Description |
|--------------------------|---|
| ExternActivate | Input permanently wired to 24 VDC = Activates the external trigger function |
| ExternStart / ExternStop | Connect both inputs to the same digital output that the master uses to notify the X20ET8819 when to start and stop recording. The master can, for example, always set the output before the drive start command and reset it as soon as the startup has been completed. When the master detects an error, it only has stop setting the output. This would mean that after 30 hours the recording is certain to contain the time period in which the error occurred and as well as a few prior recordings of proper startups for comparison. |

Table 480: Function of the inputs in Example 1

Example 2

A system containing multiple X20 I/O systems on the POWERLINK network is experiencing sporadic failures. An I/O slave suddenly fails for no apparent reason after running properly for a long time. To analyze whether the failure is network related, the time before the failure must be recorded.

Problems:

The master has no indication as to when and why the problem occurs. That means there is no start condition for the recording. Someone would have to stay on the analysis PC the whole time to stop recording when the error occurs.

Solution:

| Input | Description |
|----------------|--|
| ExternActivate | Input permanently wired to 24 VDC = Activates the external trigger function |
| ExternStart | Input permanently wired to 24 VDC = Ensures that the recording starts immediately when the X20ET8819 is turned on |
| ExternStop | Connect input to a digital output on the affected I/O slave, which is permanently set to 1 by the program. As soon as the slave fails the first time and resets the digital outputs, recording is stopped by the negative edge on ExternStop and is not started again. |

Table 481: Function of the inputs in Example 2

9.24.2.16 Using trigger outputs

| Output | Name | Description |
|--------|------------|--|
| 1 | FrameError | As soon as a frame error (CRC, Oversize, Preamble, Noise or Alignment) occurs, this output is set for 10 ms. |
| 2 - 12 | - | Reserved |

Table 482: Using trigger outputs in the event of an error

9.24.2.17 B&R recording software

The recording plug-in (for WildPackets OmniPeek) to decode the capture frames is available for download in the Download section on the B&R homepage.

B&R provides the following free recording software for the module in the Downloads section of the B&R website:

- Ethernet Analyzer Plugin for Wildpackets OmniPeek
- B&R Network Analyzer (stand-alone solution)

9.24.3 X20(c)HB8815

Data sheet version: 1.44

9.24.3.1 General information

The POWERLINK TCP/IP gateway enables the exchange of all types of application data (HMI, diagnostics, parameter data, etc.) between a POWERLINK V2 network and a TCP/IP network. It functions like a layer 2 switch, with the exception that cyclic POWERLINK packets are not routed to the ETH port.

With respect to the functionality of layer 2 switches, it should be mentioned that the gateway uses the store-and-forward principle. Gateway functionality doesn't need to be configured separately.

When the gateway receives a frame, it saves the MAC address of the sender and the corresponding interface in the source address table (SAT). If the destination address is found in the SAT, the gateway routes the frame to the corresponding interface. Frames with a broadcast or multicast address are always routed to all interfaces.

When IP packets are received at the "ETH" port that are larger than the MTU configured for POWERLINK, they are fragmented, if permitted.

- "ETH" port: Interface for TCP/IP network
- "PLK" port: Interface for POWERLINK network

Information:

**I/O modules cannot be operated with the X20HB8815.
POWERLINK V1 is not supported.**

POWERLINK is a standard protocol for Fast Ethernet equipped with hard real-time characteristics. The POWERLINK Standardization Group (EPSG, see www.ethernet-powerlink.org) ensures its openness and continual development.

The bus modules expanded to the left allow connection of up to 2 hub expansion modules in addition to the gateway. This means that a basic device provides up to 2 POWERLINK ports.

- POWERLINK
- Up to 2 slots for hub expansion modules
- 3x / 5x POWERLINK hub

9.24.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.24.3.2.1 Starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.24.3.3 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | X20 hub system |  |
| X20HB8815 | X20 POWERLINK - TCP/IP gateway, can be expanded with active hub modules, 2x RJ45 | |

9.24.3.5 Operating and connection elements

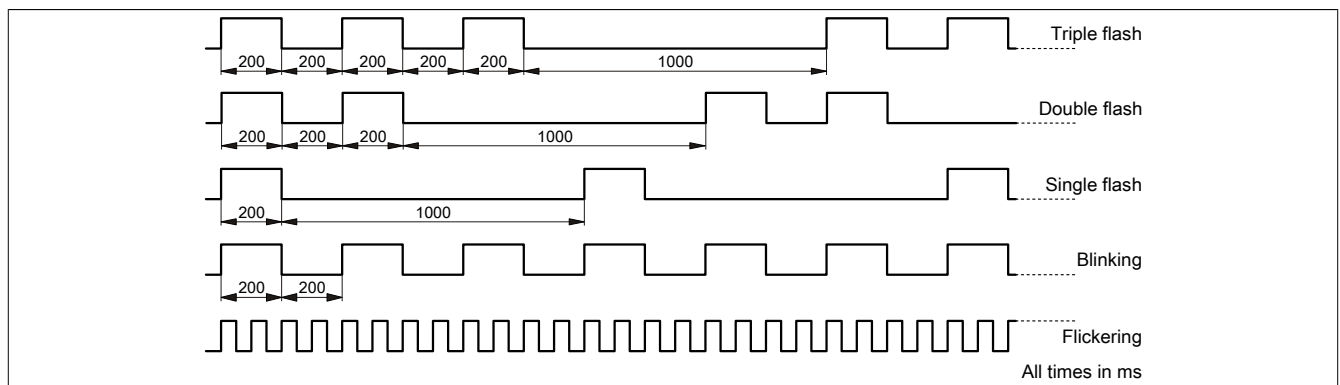

9.24.3.5.1 LED status indicators

| Figure | LED | Color | Status | Description |
|---|-------------------|----------|--------------|---|
|  | S/E ¹⁾ | Green | Off | No power supply or mode NOT_ACTIVE. The controlled node (CN) is either not supplied with power, or it is in state NOT_ACTIVE. The CN waits in this state for about 5 seconds after a restart. Communication is not possible with the CN. If no POWERLINK communication is detected during these 5 seconds, the CN enters state BASIC_ETHERNET (flickering). If POWERLINK communication is detected before this time expires, however, the CN immediately enters state PRE_OPERATIONAL_1. |
| | | | Flickering | Mode BASIC_ETHERNET. The CN has not detected any POWERLINK communication. In this state, it is possible to communicate directly with the CN (e.g. with UDP, IP, etc.) If communication POWERLINK is detected in this state, the CN switches to PRE_OPERATIONAL_1. |
| | | | Single flash | PRE_OPERATIONAL_1 mode. The CN waits until it receives an SoC frame and then switches to the PRE_OPERATIONAL_2 state. |
| | | | Double flash | PRE_OPERATIONAL_2 mode. The CN is normally configured by the manager in this state. A command then switches the CN to the READY_TO_OPERATE state. |
| | | | Triple flash | READY_TO_OPERATE mode. The manager switches the CN via command to the OPERATIONAL state. |
| | | | On | Mode OPERATIONAL. The PDO mapping is active and cyclic data is evaluated. |
| | | | Blinking | Mode STOPPED. Output data is not being output, and no input data is being provided. It is only possible to switch to or leave this state after the manager has given the appropriate command. |
| | | | On | The controlled node (CN) is in an error state (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: |
| | | Red | On | <ul style="list-style-type: none"> PRE_OPERATIONAL_1 PRE_OPERATIONAL_2 READY_TO_OPERATE  <p>Note:</p> <ul style="list-style-type: none"> Several red blinking signals are displayed immediately after the device is switched on. This is not an error, however. The LED is lit red for CNs with configured physical node number 0 but that have not yet been assigned a node number via dynamic node allocation (DNA). |
| | | L/A ETH1 | Green | On |
| | | | Blinking | A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus |
| | L/A PLK2 | Green | On | A link to the peer station has been established (POWERLINK network). |
| | | | Blinking | A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus |

1) The Status/Error LED "S/E" is a green/red dual LED.

Status LED - Blinking patterns

9.24.3.5.2 POWERLINK node number switches

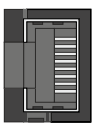

The node number for the POWERLINK node is set using the two number switches.

| Switch position | Description |
|-----------------|--|
| 0x00 | Only permitted when operating the POWERLINK node in DNA mode. |
| 0x01 - 0xEF | Node number of the POWERLINK node. Operation as a controlled node. |
| 0xF0 - 0xFF | Reserved, switch position not permitted. |

9.24.3.5.3 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see "[Cabling guidelines for X20 modules with an Ethernet cable](#)" on page 58.

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

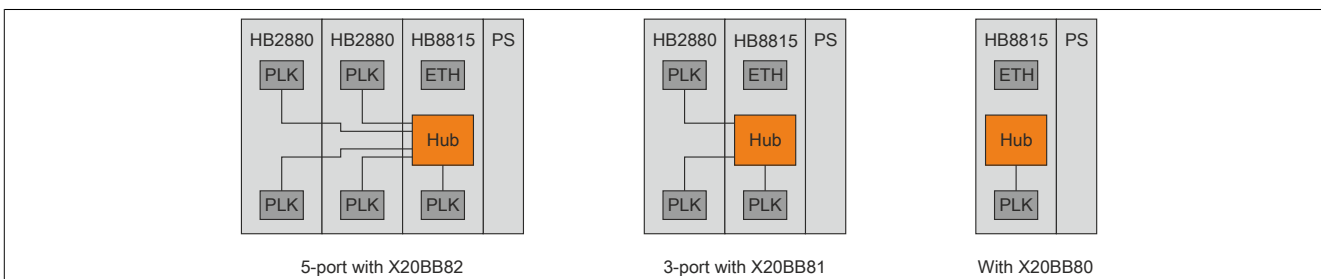

9.24.3.5.4 Slot for hub expansion modules

Depending on the bus base, up to 2 hub expansion modules can be installed on the left side of the module:

| Bus base | Slots for hub expansion modules |
|----------|---------------------------------|
| X20BB81 | 1 |
| X20BB82 | 2 |

Table 485: Slots for hub expansion modules for various bus bases

The hub expansion module for the gateway is a 2x hub, which allows the gateway to be expanded into a 5x POWERLINK hub.

9.24.3.6 Usage examples

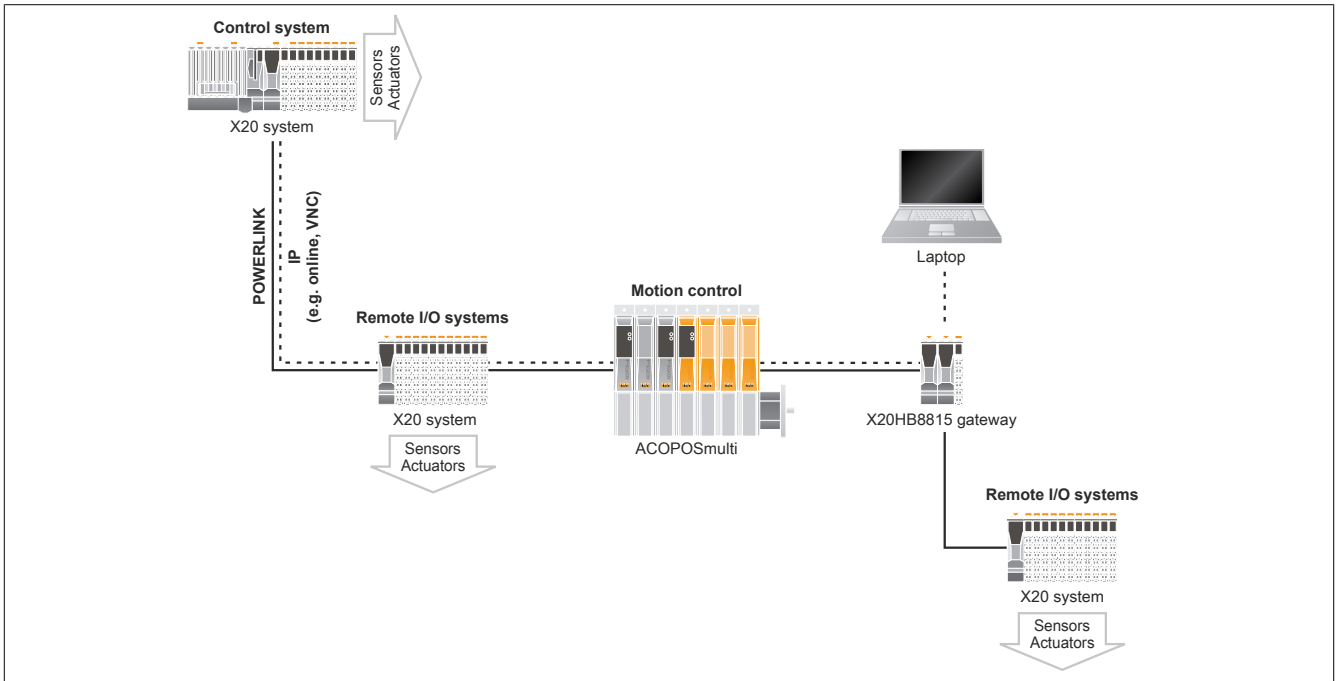

Information:

The X20HB8815 can also be operated as an async-only controlled node. Make sure that the node number is between 1 and 239 and that it is physically present and not yet being used in the POWERLINK network.

Information:

A direct connection via Ethernet (PC control system) is faster than a connection via the X20HB8815 since the available bandwidth must be shared with the POWERLINK protocol.

9.24.3.6.1 Example 1: Online connection with Automation Studio or SDM via POWERLINK

1. The following settings must be made on the POWERLINK manager interface.

- The desired IP address and subnet mask must be entered under the Ethernet parameters. This IP address is not permitted to overlap the POWERLINK default subnet address 192.168.100.x and the configured POWERLINK NAT subnet.
- INA communication must be enabled.

| | |
|--------------------------------|---------------------------|
| Ethernet parameters | |
| Activate Ethernet communic... | on |
| Device name | <InterfaceAddress>.ETH |
| Redundant parameter | Single CPU Project |
| Mode | enter IP address manually |
| Host name | |
| IP address | 10.0.8.10 |
| Subnet Mask | 255.255.255.0 |
| INA parameters | |
| Activate online communicati... | on |

If required, the web server and SDM must be enabled in Automation Studio.

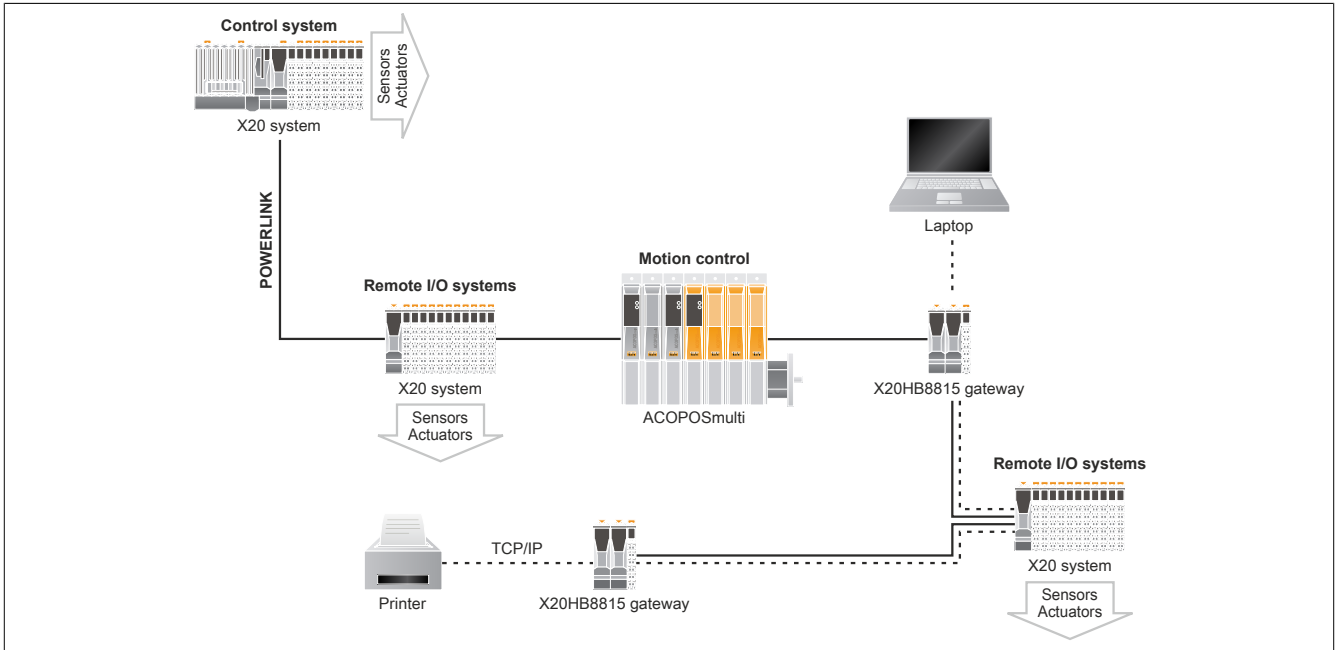

2. The following settings must be made on the PC:

- The IP address of the Ethernet interface must be located in the same subnet as the configured IP address (Ethernet parameters) of the POWERLINK interface. Otherwise, a route must be set manually.

Information:

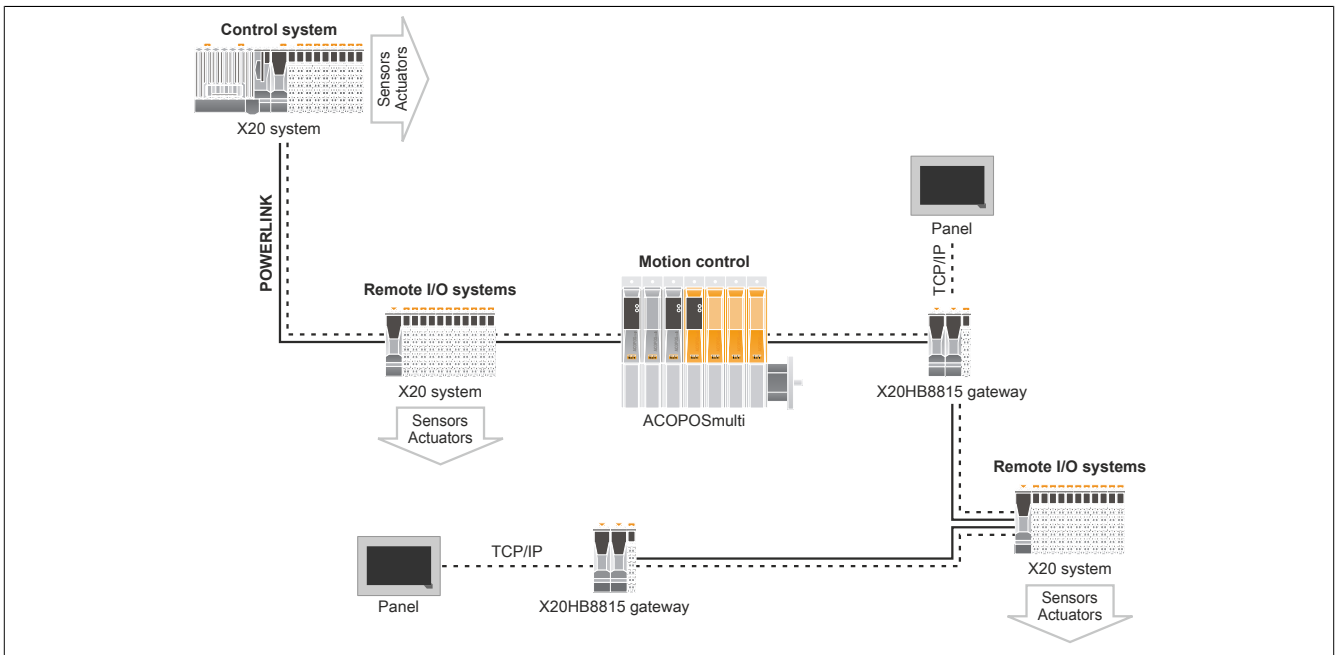

The search for destinations (SNMP) does not work via the X20HB8815.

9.24.3.6.2 Example 2: Using a POWERLINK network for TCP/IP services

With the 2 devices connected via the X20HB8815, it is important to make sure that they are in the same IP subnet and that corresponding routes are set.

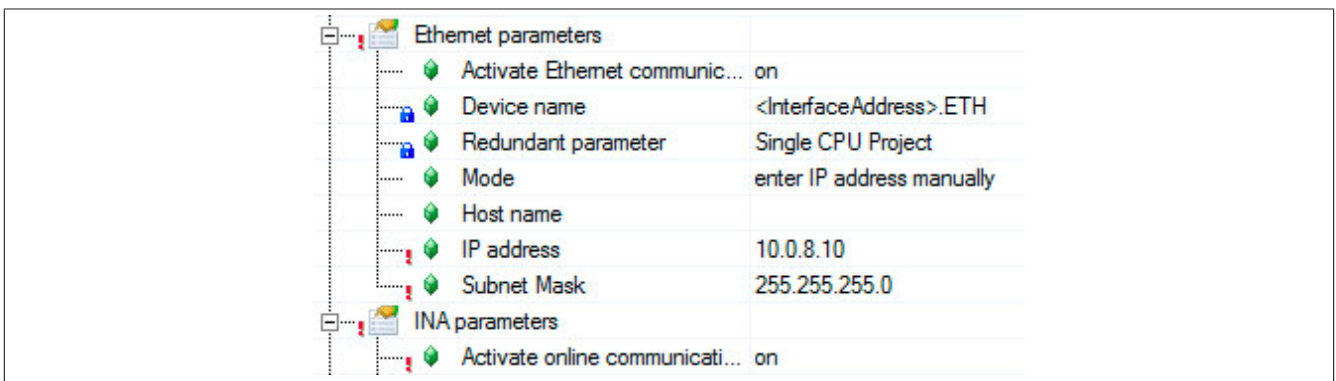

9.24.3.6.3 Example 3: Terminal panel via POWERLINK using X20HB8815

A terminal panel can be operated with POWERLINK using a X20HB8815 and VC3.95.6 or higher.

The following settings must be made on the POWERLINK manager interface.

- The desired IP address and subnet mask must be entered under the Ethernet parameters. This IP address is not permitted to overlap the POWERLINK default subnet address 192.168.100.x and the configured POWERLINK NAT subnet.
- INA communication must be enabled.

Information:

The terminal or T-Series panel must be attached to the ETH port in Automation Studio and have an IP configured that is located in the subnet of the POWERLINK Manager (under Ethernet parameters configured IP subnet).

T-Series Panel: Only works with this application over VNC. The configured IP address (Ethernet parameters) must be used as the terminal server IP address.

9.24.3.7 SG3

This module is not supported on SG3 target systems.

9.24.3.8 Firmware

The module comes with preinstalled firmware. The firmware is part of the Automation Studio project. The module is automatically brought up to this level.

To update the firmware contained in Automation Studio, a hardware upgrade must be performed (see "Project management / Workspace / Upgrades" in Automation Help).

When using a 3rd-party device as a POWERLINK manager, the firmware update can be performed via the integrated Web server.

9.24.3.9 MTU size

Automatic MTU configuration is currently not supported. The MTU size is set to 300 (default value).

The MTU can be set manually under "Asynchronous Optimization" -> "Local ASnd MTU" in the I/O configuration of the module.

9.24.3.10 Asynchronous send priority

If needed, a higher asynchronous send priority can be assigned to the module. The setting for this is made in the I/O configuration of the module under "Asynchronous Optimization" -> "Asynchronous Send Priority".

Information:

If the priority is set too high, it is possible in some circumstances that other POWERLINK stations cannot send their asynchronous data on time.

9.24.4 X20(c)HB8880

Data sheet version: 2.41

9.24.4.1 General information

The X20 hub is a device that can be used universally in standard Ethernet networks or POWERLINK networks. It is suitable for 100 Mbit/s (Fast Ethernet) networks.

The bus modules expanded to the left allow connection of up to 2 hub expansion modules in addition to the hub base module. This means that a single base device provides up to 6 hub interfaces.

- 2x / 4x / 6x Fast Ethernet hub
- Modular construction
- Easily expandable

9.24.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.24.4.2.1 -40°C starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C. During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.24.4.3 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | X20 hub system |  |
| X20HB8880 | X20 base hub module, integrated 2-port hub, 2x RJ45 | |

Table 487: X20HB8880, X20cHB8880 - Technical data

1) Spacing is based on the width of the X20BB80 bus base. Up to two X20HB2880 hub expansion modules and one X20PS8002 supply module are also always required for the hub.

9.24.4.5 LED status indicators

| Figure | LED | Color | Status | Description |
|---|---------|-------|----------|--|
|  | S | Green | On | Hub is active |
| | L/A IFx | Green | On | A link to the remote station has been established. |
| | | | Blinking | A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus. |

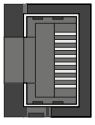

9.24.4.6 Operating and connection elements

9.24.4.7 Ethernet interface

For information about wiring X20 modules with an Ethernet interface, see "[Cabling guidelines for X20 modules with an Ethernet cable](#)" on page 58.

| Interface | Pinout | | |
|--|--------|-------------|----------------|
| | Pin | Ethernet | |
|  Shielded RJ45 | 1 | RXD | Receive data |
| | 2 | RXD\ | Receive data\ |
| | 3 | TXD | Transmit data |
| | 4 | Termination | |
| | 5 | Termination | |
| | 6 | TXD\ | Transmit data\ |
| | 7 | Termination | |
| | 8 | Termination | |

9.24.4.8 Slot for hub expansion modules

Depending on the bus base, up to 2 hub expansion modules can be installed on the left side of the X20 hub:

| Bus base | Slots for hub expansion modules |
|----------|---------------------------------|
| X20BB81 | 1 |
| X20BB82 | 2 |

The hub expansion module is a 2x hub, which allows the hub base module to be expanded into a 6x hub.

9.24.4.9 Network size and collision detection

Information:

This section applies to the use of Ethernet networks, not POWERLINK networks.

According to Ethernet specification IEEE 802.3, the transmission duration of a frame of minimum length must always be greater than the round-trip delay time (RTD). RTD is the time needed by a data packet to travel from one end of the network to the other.

If this is not observed, collision detection can no longer be guaranteed.

Illustration of RTD

When using copper cables, the maximum distance is generally 100 m. Since there are often many different devices with different PHYs in a network, the propagation delay of the frames changes due to the different latency of each PHY. This also affects the network size, and collision detection can no longer be guaranteed at 100 m.

Example for calculating network size

The following parameters are specified for a network:

- Transfer rate: 100 Mbit/s
- Cable length: 100 m
- Number of hubs: 2
- Hub propagation delay of a frame: 1 μ s
- Minimum frame size in the Ethernet network: 72 bytes

Calculation procedure

| | |
|---|---|
| 1. How long does 1 byte take at 100 Mbit/s? – 100 Mbit/s / 8 = 12.5 MB/s | $\frac{12,500,000}{1} = \frac{1}{x}$ $x = \frac{1s}{12,500,000} = 80ns$ |
| 2. Propagation delay of minimum Ethernet frame – Minimum frame in Ethernet network: 72 bytes | $72 * 80ns = 5.76\mu s$ |
| 3. Propagation delay in cable and hub – 100 m cable = 0.5 μ s – 2 hubs = 2 x 1 μ s | $2\mu s + 0.5\mu s = 2.5\mu s$ |
| 4. Calculation of total propagation delay – Outbound/Inbound propagation delay | $2.5\mu s * 2 = 5\mu s$ |
| Result Collision detection is possible since the total time of 5 μ s is less than the minimum Ethernet propagation delay of 5.76 μ s. | |

Example for calculating the network reach with devices between 2 stations

Corresponding to the previous example, the following situation occurs in a network with 3 hubs and 100 m cables:

- The transmission duration of a frame of minimum length is 5.76 μ s.

Calculation procedure

| | |
|--|--------------------------------|
| 1. Propagation delay in cable and hub – 100 m cable = 0.5 μ s – 3 hubs = 3 x 1 μ s | $3\mu s + 0.5\mu s = 3.5\mu s$ |
| 2. Calculation of total propagation delay – Outbound/Inbound propagation delay | $3.5\mu s * 2 = 7\mu s$ |
| Result Collision detection is not possible since the total time of 7 μ s is greater than the minimum Ethernet propagation delay of 5.76 μ s. The ≈ 1.3 μ s missing for collision detection can only be recovered by removing a hub. | |

9.25 Motor controllers

The motor controllers offer extensive possibilities for controlling motors, valves or resistive loads and are particularly well suited for controlling brush DC motors. Each output is assigned a status LED.

9.25.1 Summary

| Model number | Short description | Page |
|--------------|---|------|
| X20MM2436 | X20 PWM motor module, 24 to 39 VDC $\pm 25\%$, 2 PWM motor bridges, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder | 2496 |
| X20MM3332 | X20 digital motor module, 24 VDC, 3 digital outputs, full bridge (H bridge), 3 A continuous current, 5 A peak current | 2523 |
| X20MM4331 | X20 digital motor module, 24 VDC, 4 digital outputs, half bridge, 3 A continuous current, 5 A peak current | 2538 |
| X20MM4455 | X20 PWM motor module, 24 to 48 VDC $\pm 25\%$, 4 PWM motor bridges, 6 A continuous current, 10 A peak current, 4x 3 digital inputs 5 VDC single-ended, source, configurable as incremental encoder | 2551 |
| X20MM4456 | X20 PWM motor module, 24 to 48 VDC $\pm 25\%$, 4 PWM motor bridges, 6 A continuous current, 10 A peak current, 4x 4 digital inputs 24 VDC, sink, configurable as incremental encoder | 2577 |
| X20SM1426 | X20 stepper motor module, 1 motor connection, 1 A continuous current, 1.2 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder, NetTime function | 2603 |
| X20SM1436 | X20 stepper motor module, module power supply 24 to 39 VDC $\pm 25\%$, 1 motor connection, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder, NetTime function | 2652 |
| X20SM1436-1 | X20 stepper motor module, with current reduction function, module power supply 24 to 48 VDC $\pm 25\%$, 1 motor connection, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder, NetTime function | 2700 |
| X20SM1446-1 | X20 stepper motor module, module power supply 24 to 48 VDC $\pm 25\%$, with current reduction function, 1 motor connection, 5 A continuous current, 10 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder, NetTime function, double-width module | 2751 |
| X20cMM2436 | Coated X20 PWM motor module, 24 to 39 VDC $\pm 25\%$, 2 PWM motor bridges, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder | 2496 |

Table 488: X20MM2436, X20cMM2436 - Order data

9.25.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.25.2.2.1 Starting temperature

The starting temperature describes the minimum permissible ambient temperature when the power is switched off at the time the coated module is switched on. This is permitted to be as low as -40°C . During operation, the conditions as specified in the technical data continue to apply.

Information:

It is important to absolutely ensure that there is no forced cooling by air currents in a closed control cabinet, for example using a fan or ventilation slots.

9.25.2.3 Module description

The motor bridge module is used to control 2 DC motors with a nominal voltage of 24 to 39 VDC \pm 25% at a nominal current up to 3 A.

Functions:

- [Counters](#)
- [Standard PWM/current mode](#)
- [Frequency mode](#)
- [SuperVibe mode](#)
- [Valve control](#)
- [Automatic shutdown](#)

Digital counter inputs

The module is equipped with 4 digital inputs that can additionally be used as incremental counters. In addition to AB(R) and event counters, period duration and gate measurements are also possible.

Operating modes

The PWM outputs of the module can be controlled in 3 different operating modes. In addition to the standard PWM mode, a special current mode for controlling inductive loads and PWM control with reversed edges is available. This allows the module to be adapted to a wide range of applications.

Valve control

The module can be used to control valves. To prevent the valves from sticking, a dither can be configured exactly according to the specifications of the valve manufacturer.

Automatic shutdown

The voltage of the I/O power supply, the motor current and the module temperature are monitored. If a value overshoots the predefined limit value, the module is automatically switched off. As soon as the value is within the limit value again, the outputs of the module are automatically started up.

9.25.2.5 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|---|--------|-------|-----------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | e + r | | Red on / Green single flash | Invalid firmware |
| | 1 - 4 | | Green | Input state of the corresponding digital input |
| | M1, M2 | | Orange | On |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.25.2.6 Pinout

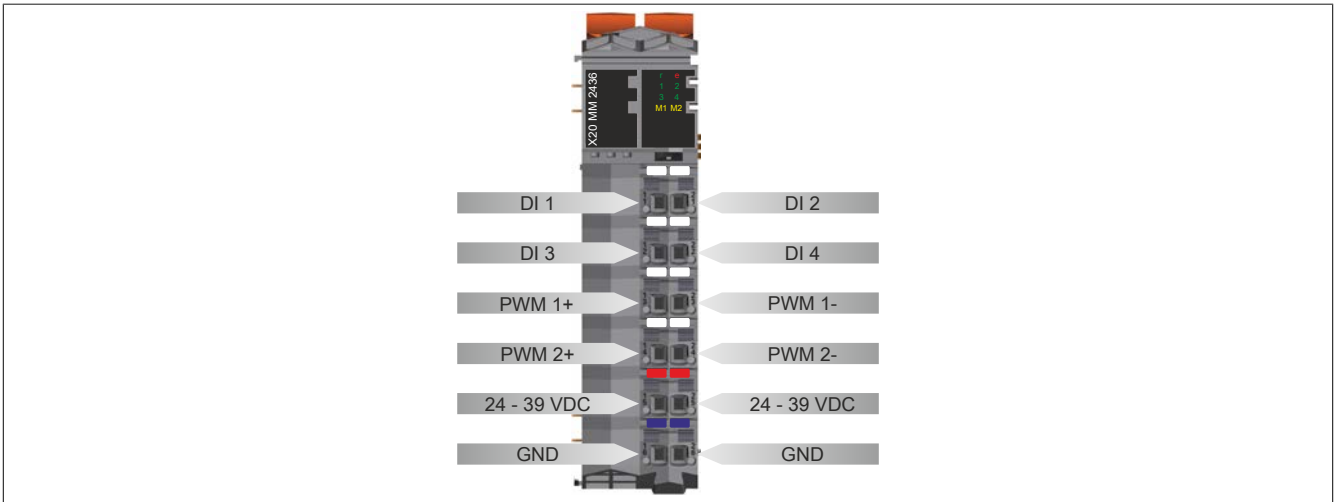

In accordance with the EN 60204-1 standard, a cable cross section of 0.75 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 3.5 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

The terminal block is not permitted to be plugged in or unplugged during operation.

Information:

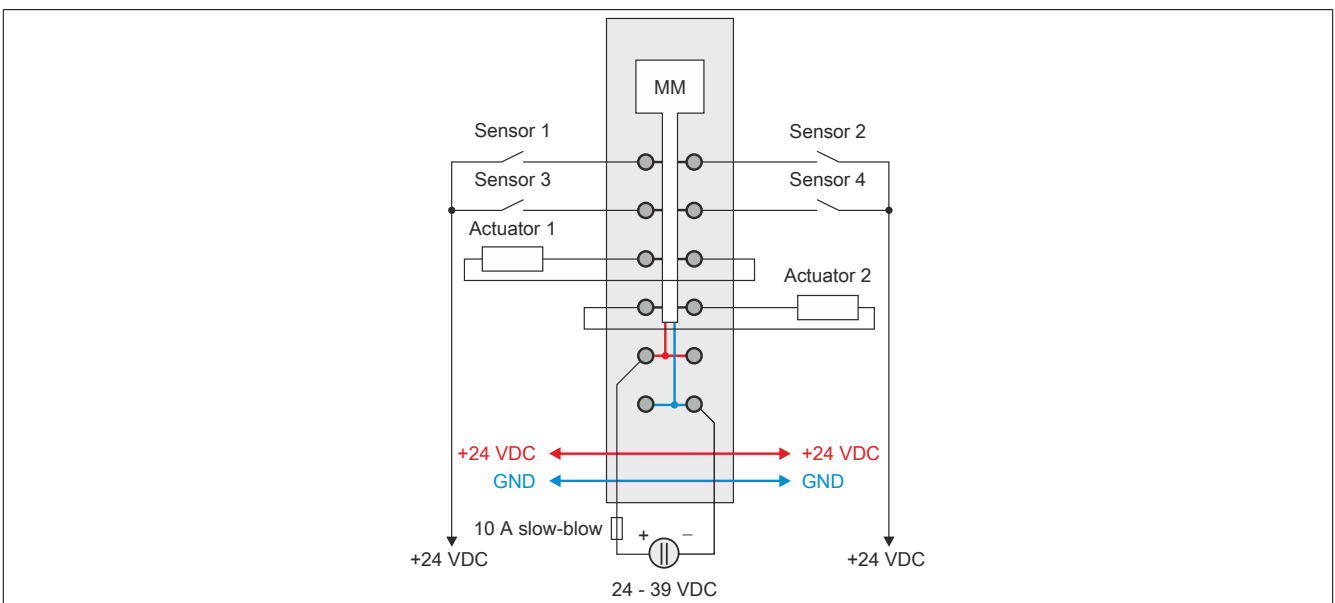

Shielded motor cables must be used in order to meet the limits according to the EN 55011 standard (emissions).

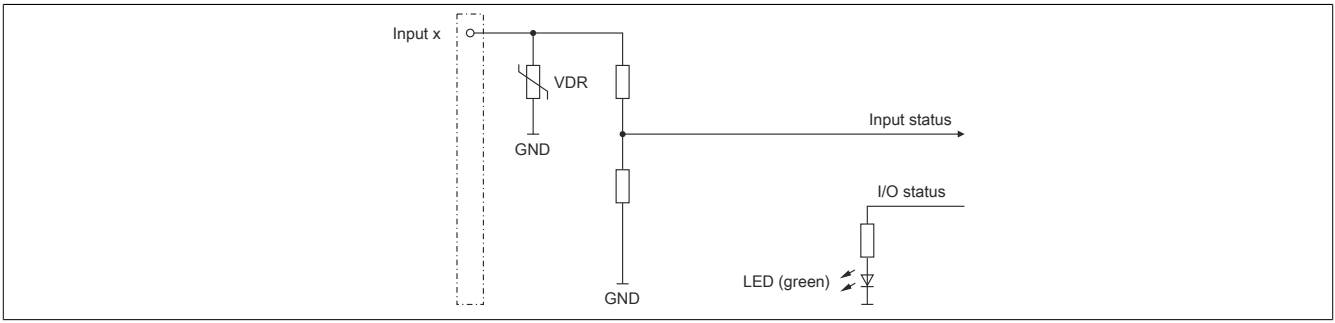

9.25.2.7 Connection example

Information:

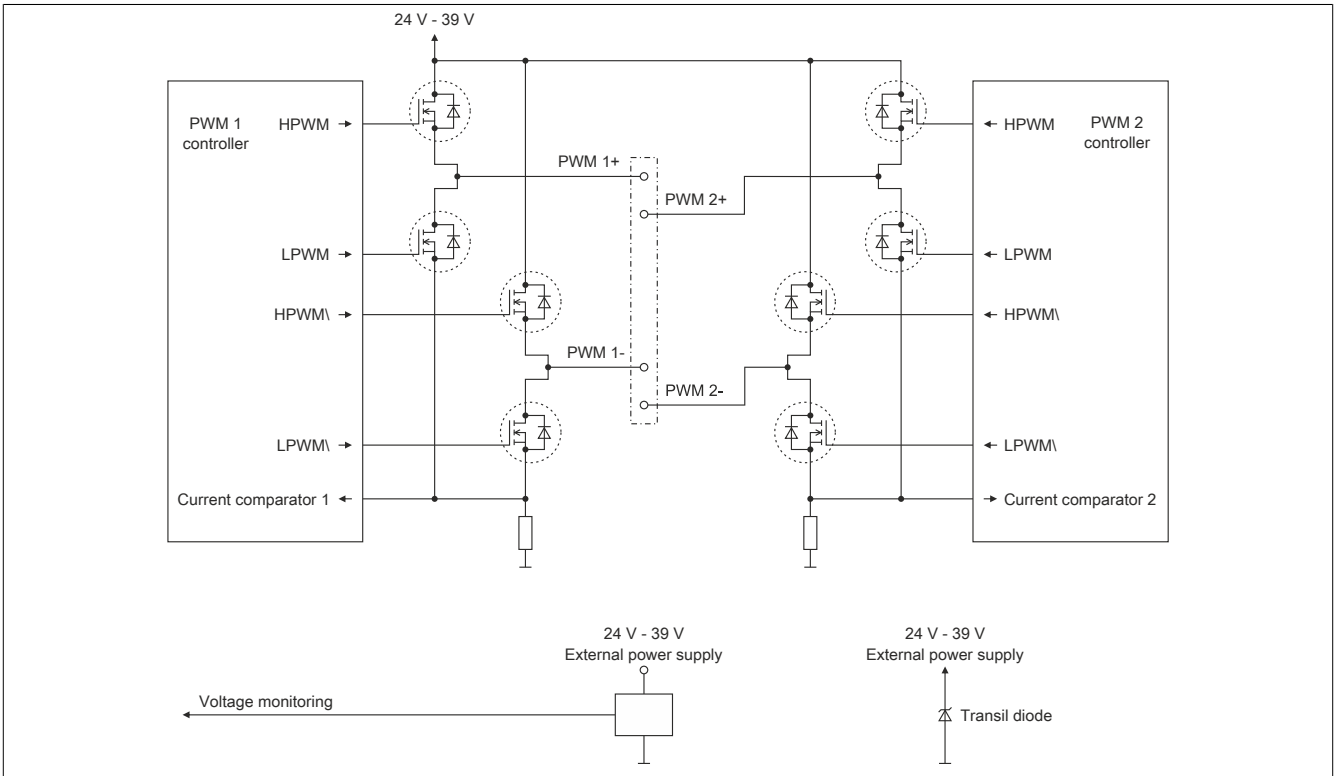

This module can only be operated if supplied with power via the terminal block.

9.25.2.8 Input circuit diagram

9.25.2.9 Output circuit diagram

9.25.2.10 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load but is always less than the motor current. Make sure the maximum nominal current of 7 A is not exceeded on the power supply terminals of the power element.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the mains power input and the rated current of the used fuse are chosen according to the current-carrying capacity such that the permissible current-carrying capacity of the selected cable cross section (depending on wiring, see table) is greater than or equal to the current load in the mains power input. The rated current of the fuse protection must be less than or equal to the permissible current-carrying capacity of the selected cable cross section (depending on the how it is installed, see table):

$$I_{\text{Power system}} \leq I_{\text{Fuse}} \leq I_{\text{Line/cable}}$$

| Wire cross section [mm ²] | Current-carrying capacity of cable cross section I_z / rated current of fuse I_b [A] depending on the to type of wiring at an ambient air temperature of + 40°C per EN 60204-1 | | | |
|---------------------------------------|--|-----------|-----------|-----------|
| | B1 | B2 | C | E |
| 1.5 | 13.5 / 13 | 13.1 / 10 | 15.2 / 13 | 16.1 / 16 |
| 2.5 | 18.3 / 16 | 16.5 / 16 | 21 / 20 | 22 / 20 |

Table 490: Cable cross section of the mains power input depending on the type of wiring

The tripping current of the fuse is not permitted to exceed the rated current of the fuse I_b .

| Type of wiring | Description |
|----------------|--|
| B1 | Wires in conduit or cable duct |
| B2 | Cables in conduit or cable duct |
| C | Cables or wires on walls |
| E | Cables or wires on open-ended cable tray |

Table 491: Type of wiring used for the mains power input

9.25.2.11 Derating

To ensure proper operation, the following items must be taken into consideration:

- The sum of the square of both effective currents (I_N , peak value must not exceed 3 A) must not exceed $9 A^2$. The boost current of 3.5 A for 2 seconds is an exception.
- Modules next to the motor module can have a maximum power consumption of 1 W.
- The derating values listed below must be taken into consideration

Example calculations

In the following examples, the calculation of I_N^2 is used to check if the current operating state is permitted.

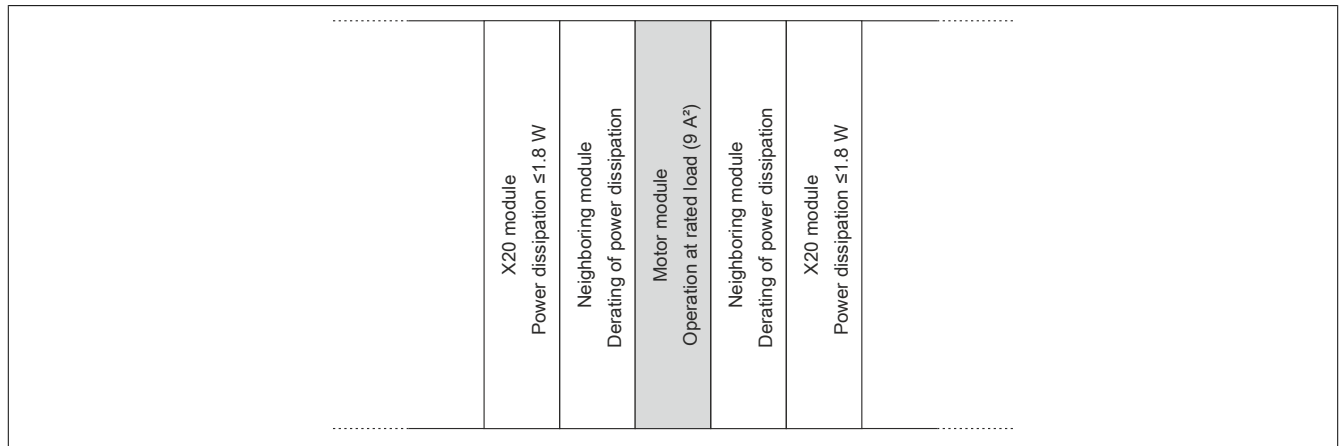

| Output current | | I_N^2 | Operating state permitted |
|----------------|-------|--|----------------------------|
| PWM 1 | PWM 2 | | |
| 3 A | 0 A | $I_N^2 = 3 A \cdot 3 A + 0 A \cdot 0 A = 9 A^2$ | Yes |
| 2.1 A | 2.1 A | $I_N^2 = 2.1 A \cdot 2.1 A + 2.1 A \cdot 2.1 A = 8.82 A^2$ | Yes |
| 2.8 A | 2 A | $I_N^2 = 2.8 A \cdot 2.8 A + 2 A \cdot 2 A = 11.84 A^2$ | for max. 2 s ¹⁾ |

1) The cooling time, which means operation $<9 A^2$, must be at least 5 times as long as the time of the overload.

Power loss derating for neighboring modules

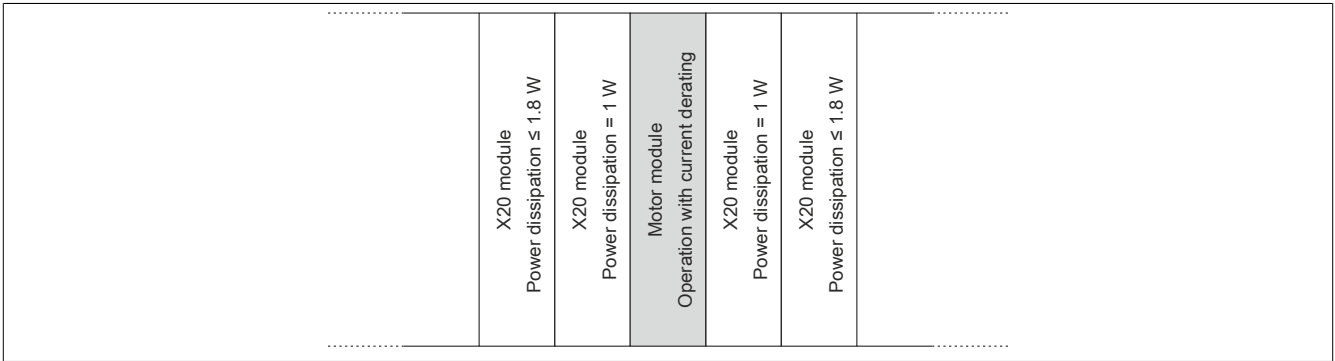

Modules directly next to the motor module can have a power loss of 1 W. If the motor module is operated with the rated load over the entire temperature range ($9 A^2$), a derating for power loss of the neighboring modules must be adhered to starting at $45^\circ C$.

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

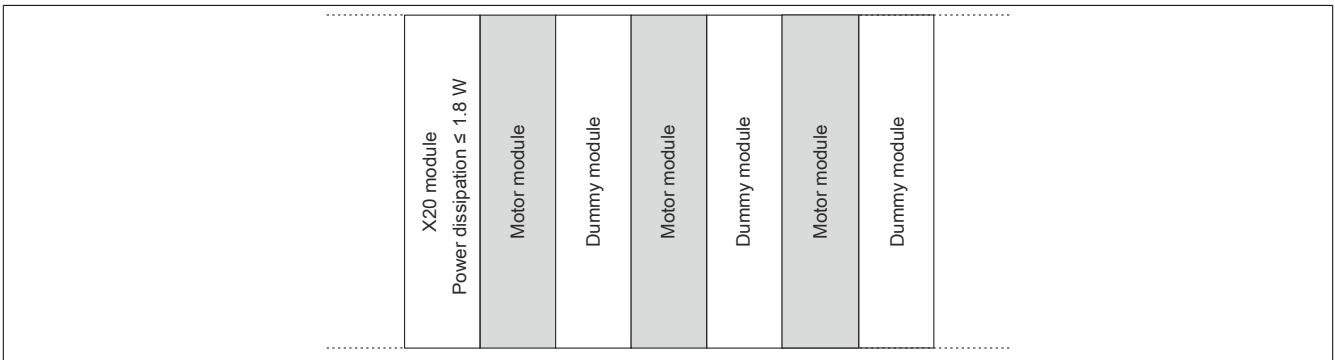

Current derating of the motor module

If the power loss of the neighboring modules to the motor module is 1 W, then the current of the motor module must be derated starting at 45°C.

Hardware configuration for multiple motor modules

If three or more motor modules are operated in a cluster, a dummy module must be inserted between the motor modules. There is no derating in this configuration.

9.25.2.12 Function description

9.25.2.12.1 Counters

The following counter types or measurements can be configured on the module:

- AB counters
- ABR counter (only counter 1)
- Event counters
- Period measurement
- Gate measurement

Counter function - Assignment of the digital inputs:

| Counter function | Counter number | A | B | R | Enable reference | Counter input | Period duration and gate signal | External measuring frequency |
|--------------------------------------|----------------|------|------|------|------------------|---------------|---------------------------------|------------------------------|
| Incremental counter | 1 | DI 1 | DI 2 | DI 3 | DI 4 | | | |
| | 2 | DI 3 | DI 4 | | | | | |
| Event counters | 1 | | | | | DI 1 | | |
| | 2 | | | | | DI 3 | | |
| Period duration and gate measurement | 1 | | | | | | DI 1 | DI 2 |
| | 2 | | | | | | DI 3 | DI 4 |

Information:

For the configuration, see ["Counter configuration 1" on page 2514](#) and ["Counter configuration 2" on page 2515](#).

9.25.2.12.2 Operating modes

The outputs of the module can be operated in different modes. The following table lists the differences between the different operating modes:

| Operating mode | Standard PWM/ current mode | Frequency mode 1 | Frequency mode 2 | SuperVibe mode |
|--------------------------------|--|---|--|---|
| Operating modes | PWM control Current control | Frequency mode | | SuperVibe control PWM control |
| Starting with firmware version | - | 7 | 7 | 8.02 |
| Frequency setting | 1x period duration in μs | 2x in 1/10 or 1/100 Hz | 1x in 1/10 or 1/100 Hz | 2x in 1/10 or 10 Hz |
| Duty cycle / Current setting | 2x -100 to 100% | 1x -100 to 100% | 2x -100 to 100% | 2x -100 to +100% |
| Dither | Yes | No | No | No |
| Decay mode setting | Yes | No | No | No |
| Channel reference | PWM start from channel 2 offset 180° compared to channel 1 | A fixed phase relationship between channel 1 and channel 2 is not possible. | PWM start from channel 2 offset 180° compared to channel 1 | A fixed phase relationship between channel 1 and channel 2 is not possible. |
| | 3.5 A per channel | 1 A per channel | 3.5 A per channel | Maximum 1 A per channel |

Information:

For the configuration, see ["Module configuration" on page 2515](#).

9.25.2.12.2.1 PWM control Standard PWM/current mode

PWM control

The following image illustrates how the current curves for the outputs are affected by registers [PWM period duration](#) and [PWM pulse width](#).

At the beginning of each period, the output is switched on for the percentage of time set in the PWM pulse width. The period duration is specified in μs .

Current control

The following image illustrates how the current curves for the outputs are affected by registers [PWM period duration](#) and [PWM pulse width](#).

At the beginning of each period, the current output is switched on. After reaching the value set in PWM pulse width, the output is switched off and the voltage drops according to the [decay configuration](#) until switched back on.

9.25.2.12.2.2 Frequency mode

The following image illustrates how the current curves for the outputs are affected by registers [Frequency](#) and [Duty cycle](#).

At the beginning of each period, the output is switched on for the percentage of time set in the duty cycle. The frequency is specified in Hz depending on register [FrequencyPrescale](#).

Depending on the operating mode, the following settings are possible:

- Frequency mode 1: Frequency is individually adjustable for PWM outputs; duty cycle is identical for PWM output 1 and 2.
- Frequency mode 2: Frequency is identical for PWM output 1 and 2; duty cycle can be set individually for PWM outputs.

9.25.2.12.2.3 SuperVibe mode

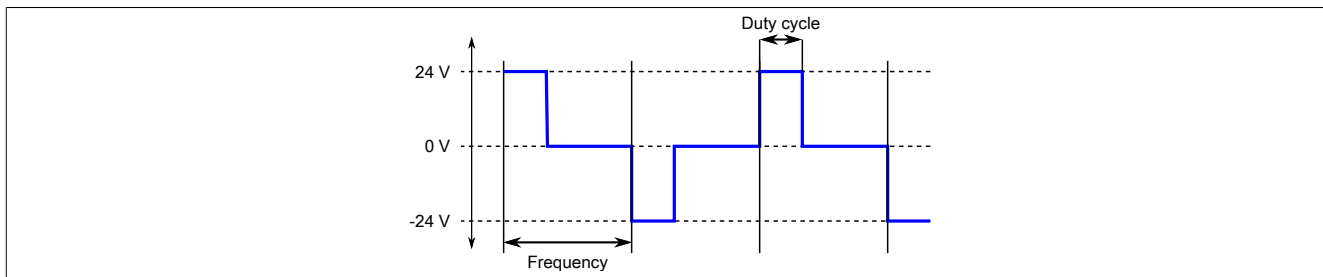

Information:

Only available with firmware version 8.02 or later.

SuperVibe control

SuperVibe (edge polarity reversal) is switched on.

Every second PWM edge is reversed. The following image illustrates how the current curves for the outputs are affected by registers [Frequency](#) and [Duty cycle](#).

PWM control

SuperVibe (edge polarity reversal) is switched off.

The PWM output is contained as described in [Frequency mode](#). [Frequency](#) and [Duty cycle](#) are configurable for each PWM output, however.

9.25.2.12.3 Valve control

When the position setpoint for valves remains constant for a long period of time, especially in fluids, there is a risk that a valve will stick. This is normally prevented using "dithering". When doing so, the value is permitted to slightly oscillate around the position setpoint.

In the module, this dithering is implemented in the form of a triangle wave.

- In PWM mode, the pulse width (duty cycle) of the PWM signal oscillates.
- In current mode, the current setpoint oscillates.

Concrete values for the dither amplitude and frequency to be set must be either taken from the valve data sheet or determined empirically.

By default, the dither is active for both outputs as soon as the dither amplitude and frequency are set to a value 0. If required, dither can be disabled individually and synchronously for each output (see "[Error acknowledgment, dither switch-off and FrequencyPrescale](#)" on page 2521).

Information:

For the configuration, see "[Dither amplitude](#)" on page 2518 and "[Dither frequency](#)" on page 2518.

9.25.2.12.3.1 Dither example

The values specified in the data sheet for a valve should be used to calculate [Dither amplitude](#) and [Dither frequency](#).

Data sheet for the valve

The data sheet for a valve manufacturer recommends the following dithering:

Dither height in percent (A_{Dither}): 20 to 35% (peak values) of the nominal valve current of 2 A

Dither frequency in Hertz (F_{Dither}): 40 to 70 Hz

Selected values

These values correspond to the average values on the valve data sheet.

$A_{\text{Dither}} = 27\%$ of the valve's nominal current (peak values)

$F_{\text{Dither}} = 56 \text{ Hz}$

Formulas

Dither amplitude = $(A_{\text{Dither}} / 2) * (\text{Nominal current}_{\text{valve}} / \text{Nominal current}_{\text{Module}}) * 10$

Info: $(A_{\text{Dither}} / 2)$ = Conversion of the peak values to amplitude, " * 10" = Scaling of the dither amplitude to 1/10%

Dither frequency = $F_{\text{Dither}} / 2 \text{ Hz}$

Info: Dither frequency is configured in 2 Hz steps.

Calculation

By using the selected values in the formulas.

Dither amplitude = $27\% / 2 * (2 \text{ A} / 3 \text{ A}) * 10 = 90$

Dither frequency = $56 \text{ Hz} / 2 \text{ Hz} = 28$

9.25.2.12.4 Automatic shutdown

To prevent damage to the module or motor, both the voltage and current of the module power supply and the module temperature are monitored.

9.25.2.12.4.1 Overvoltage cutoff

The module power supply voltage is continually monitored. The "error state" on page 2520 is reported back if a voltage is higher or lower than the limit values.

If the supply voltage in the module overshoots or undershoots the limit values (e.g. during regenerative operation), the motor output is cut off.

The outputs are enabled again as soon as the supply voltage is back in the valid range. In current mode (depending on the set target current and inductance of the load), switching on the outputs again can result in error "open-load" just like any other abrupt change in the current default value.

Limit values for the supply voltage

| | Drive cut off |
|-------------|---------------|
| Lower limit | <18 V |
| Upper limit | >50 V |

9.25.2.12.4.2 Shutdown in the event of overcurrent

The output current of the PWM outputs is monitored. An overcurrent error is reported in the following cases:

- The maximum output current of a PWM output is exceeded for at least 2 seconds.
 - Standard/PWM mode: ≥ 3.5 A
 - Frequency mode 1: > 1 A
 - SuperVibe mode: Value corresponding to register "MaxCurrentConfig" on page 2516
- The output current is ≥ 5 A for the PWM cycles set in register "ToleratedShortCycles" on page 2516.

In each case, the pins of the PWM output are short-circuited and the PWM output concerned is disabled. The user must acknowledge the error (see "Error acknowledgment, dither switch-off and FrequencyPrescale" on page 2521) before a disabled PWM output can be made operational again.

9.25.2.12.4.3 Shutdown in the event of overtemperature

If the module temperature reaches or overshoots the limit value of 85°C, the module performs the following actions:

- Sets error bit "Overtemperature" on page 2520
- Cuts off the outputs (short-circuited)

As soon as the temperature sinks below 83°C, the error bit is automatically cleared by the module and the outputs become operational again.

9.25.2.12.5 Decay operation

The decay configuration can be used to determine the method and dynamics of the current reduction of inductive loads or motors.

In default mode "Slow decay", the current is automatically reduced with resistance in the load. No energy is regenerated into the module.

Mode "Mixed decay" is for applications that require a dynamic and linear reduction of current. In this mode, energy is regenerated into the module during part of the PWM cycle (fast decay).

This function is available starting with firmware V3.

Information:

For the configuration, see ["Decay configuration"](#) on page 2516.

Mixed decay

Mixed decay mode is a mix of "slow decay" and "fast decay".

A check is made at the beginning of each PWM cycle to determine if the actual current for the phases is below the current setpoint. If this is the case, PWM is enabled (On) until the set current is reached. The system switches to fast decay mode for the rest of the first half of the PWM cycle. If the current setpoint has already been exceeded at the beginning of the PWM cycle (generator operation), the system immediately switches to fast decay mode. The second half of the PWM cycle always takes place in slow decay mode.

This also permits generator operation as long as the valid range for the supply voltage has not been exceeded due to the regeneration into the DC circuit.

Mixed decay - Set / actual current, PWM frequency

Operating DC motors

In PWM mode, the motor current is limited to the maximum current (3.5 A), independent of the supply voltage.

However, the motor switches to generator operation when braking. Because of the counter EMF, which is dependent on the rotary speed, a current is generated in the module that is only limited by the internal resistance of the motor. This is not permitted to exceed 7 A (maximum 2 seconds).

The counter EMF closely corresponds to the voltage needed to achieve this speed. The maximum braking current can be calculated with the following formula.

$$I_{Brake} = U_e * \frac{PulseWidth}{100\%} * \frac{1}{R_{Motor}}$$

Example:

| | |
|------------------------------|----------------------|
| Module power supply | 38 V |
| Pulse width | 16364 (equal to 50%) |
| Internal resistance of motor | 3.5 Ω |

$$I_{Brake} = 38 \text{ V} * \frac{50}{100\%} * \frac{1}{3.5\Omega} = 5.4\text{A}$$

9.25.2.12.6 Bit resolutions of the PWM outputs

The bit resolution of the PWM outputs is 15 bits + sign. This resolution cannot be maintained in all cases, however.

Resolution in the standard PWM/current mode

Depending on the length of the period duration, the bit resolution is subject to derating due to the minimum time resolution of the PWM (10 ns).

The 15-bit resolution has a period duration of up to 328 μs. With the minimum PWM period duration of 20 μs, the PWM only has an 11-bit resolution.

Resolution in frequency- and SuperVibe mode

As with the standard PWM/current mode, the predefined duty cycle in the frequency and SuperVibe modes cannot be implemented over the entire frequency domain with the full 15-bit resolution; instead, it is subject to bit derating.

It is possible to achieve the full 15-bit resolution until about 305 or 3050 Hz (depending on the frequency range).

Resolution in frequency mode

Resolution in SuperVibe mode

9.25.2.13 Register description

9.25.2.13.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

- 1) The offset specifies the position of the register within the CAN object.
- 2) Firmware version 3 or higher.
- 3) Firmware version 7.00 or higher.
- 4) Firmware version 4 or higher.
- 5) Firmware version 8.02 or later.

9.25.2.13.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.25.2.13.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.25.2.13.4 Configuration

9.25.2.13.4.1 Counter configuration 1

Name:

CounterConfig01

This register can be used to configure counter 1.

This function is available beginning with firmware Version 4.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|------------|---|
| 0 - 2 | Sets the type of counter. | 000 | AB counter with 4x evaluation (A = DI 1, B = DI 2) (bus controller default setting) |
| | | 001 | Event counter (DI 1) |
| | | 010 | Period measurement (DI 1) |
| | | 011 | Gate measurement (DI 1) |
| | | 100 | ABR counter with 4x evaluation (A = DI 1, B = DI 2, R = DI 3, Reference enable = DI 4). Copies counter 1 to counter 2 on a reference pulse. Counter 2 is shown in the I/O map, even if it is disabled in counter configuration 2. |
| | | 101 to 111 | No counter. Counter is disabled and not shown in the I/O map. |
| 3 | Measurement starts | 0 | On rising edge of DI 1 Referencing on rising edge of DI 3 (only for ABR counters) (bus controller default setting) |
| | | 1 | At falling edge on DI 1 Referencing at falling edge on DI 3 (only for ABR counters) |
| 4 - 5 | Set the counter frequency for gate or period measurement | 00 | 4 MHz (bus controller default setting) |
| | | 01 | External via DI 2 |
| | | 10 | 31.25 kHz |
| | | 11 | Reserved |
| 6 - 7 | Set the reference input | 00 | Reference input always enabled (DI 3) (bus controller default setting) |
| | | 01 | Reserved |
| | | 10 | Enable for reference input (DI 3) if DI 4 = 0 |
| | | 11 | Enable for reference input (DI 3) if DI 4 = 1 |

9.25.2.13.4.2 Counter configuration 2

Name:

CounterConfig02

This register can be used to configure counter 2. Unlike counter 1, this counter cannot be configured as an ABR counter.

This function is available beginning with firmware Version 4.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|------------|---|
| 0 - 2 | Sets the type of counter. | 000 | AB counter with 4x evaluation (A = DI 3, B = DI 4) (bus controller default setting) |
| | | 001 | Event counter (DI 3) |
| | | 010 | Period measurement (DI 3) |
| | | 011 | Gate measurement (DI 3) |
| | | 100 to 111 | No counter. Counter is disabled and not shown in the I/O map. |
| 3 | Measurement starts | 0 | On rising edge of DI 3 (bus controller default setting) |
| | | 1 | At falling edge on DI 3 |
| 4 - 5 | Set the counter frequency for gate or period measurement | 00 | 4 MHz (bus controller default setting) |
| | | 01 | External via DI 4 |
| | | 10 | 31.25 kHz |
| | | 11 | Reserved |
| 6 - 7 | Reserved | - | |

9.25.2.13.4.3 Module configuration

Name:

ConfigOutput03

The output control for each motor can be configured separately in this register.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------------|-------|---|
| 0 | Output 1 | 0 | PWM control (bus controller default setting) |
| | | 1 | Current control or SuperVibe PWM (edge reversal) |
| 1 | Output 2 | 0 | PWM control (bus controller default setting) |
| | | 1 | Current control or SuperVibe PWM (edge reversal) |
| 2 - 3 | Operating mode ¹⁾ | 00 | Default PWM/current mode (bus controller default setting) |
| | | 01 | Frequency mode 1 (bit 0 to 1 ignored) |
| | | 10 | Frequency mode 2 (bit 0 to 1 ignored) |
| | | 11 | SuperVibe ²⁾ |
| 4 - 7 | Reserved | - | |

1) Firmware version 7.00 or later.

2) Firmware version 8.02 or later.

Information:

After switching on or resetting, only a one-time changeover from default mode "Standard PWM/current mode" to "Frequency mode 1" or "Frequency mode 2" is permitted. Later reconfigurations into another mode are ignored by the module's firmware.

9.25.2.13.4.4 Decay configuration

Name:

DecayConfig

The decay configuration determines the method and dynamics of current reduction for inductive loads or motors.

This function is available beginning with firmware version 3.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|----------|---|
| 0 - 1 | PWM 1 | 00 | Slow decay (bus controller default setting) |
| | | 01 | Mixed decay |
| | | 10 to 11 | Reserved |
| 2 - 3 | Reserved | 0 | |
| 4 - 5 | PWM 2 | 00 | Slow decay (bus controller default setting) |
| | | 01 | Mixed decay |
| | | 10 to 11 | Reserved |
| 6 - 7 | Reserved | 0 | |

9.25.2.13.4.5 Overload shutdown

Name:

ToleratedShortCycles

This register can be used to set how many periods in a row an overcurrent must be applied until it is detected as an error.

This function is available starting with firmware version 8.02.

| Data type | Values | Information |
|-----------|--------|-------------------|
| USINT | 2 to 5 | Number of periods |

9.25.2.13.4.6 Permissible maximum current

Name:

MaxCurrentConfig01 to MaxCurrentConfig02

In these registers, the maximum permissible current for PWM01 and PWM02 can be set individually in mode SuperVibe.

This function is available starting with firmware version 8.02.

| Data type | Values | Information |
|-----------|-------------|------------------------------|
| UINT | 100 to 1000 | Corresponds to 100 mA to 1 A |

9.25.2.13.4.7 PWM period duration

Name:

PeriodDurationPWM01PWM02

In this register, the period duration can be set from 20 μ s (50 kHz) to 65535 μ s (15 Hz). See also "[Operating modes](#)" on page 2505

| Data type | Value | Information |
|-----------|-------------|-----------------|
| UINT | 20 to 65535 | Time in μ s |

9.25.2.13.4.8 PWM pulse width

Name:

PulseWidthCurrentPWM01 to PulseWidthCurrentPWM02

The PWM pulse width (PWM mode) or current setting (in current mode) is entered in this register according to the setting in the module configuration register. (See also "[Operating modes](#)" on page 2505.) A negative value changes the output polarity.

Information:

In order to be software-compatible with module X67MM2436, the same scaling is used for this module. Current values larger than 3.5 A are limited to 3.5 A.

Derating must also be taken into account when using both channels (see "[Derating](#)" on page 2503).

PWM mode

| Data type | Value | Output + | Output - |
|-----------|--------|--------------------------------------|--------------------------------------|
| INT | 32767 | High | Low |
| | 16384 | PWM 50/50 | Low |
| | 0 | Low (bus controller default setting) | Low (bus controller default setting) |
| | -16384 | Low | PWM 50/50 |
| | -32767 | Low | High |

Current mode

| Data type | Value | Current mode | Note |
|-----------|------------------|--------------------------------------|--|
| INT | 22937 to 32767 | +3.5 A (max. 2 s) | Limited internally, check derating |
| | 22936 | 3.5 A (max. 2 s) | Derating must be taken into consideration. |
| | 19660 | +3 A | |
| | 0 | 0 A (bus controller default setting) | |
| | -19660 | -3 A | |
| | -22936 | -3.5 A (max. 2 s) | Derating must be taken into consideration. |
| | -22937 to -32767 | -3.5 A (max. 2 s) | Limited internally, check derating |

9.25.2.13.4.9 Frequency

Name:

FrequencyPWM01 to FrequencyPWM02 (frequency mode 1 and SuperVibe)

FrequencyPWM01PWM02 (frequency mode 2)

The frequency for PWM01 or PWM02 (depends on the mode) can be set individually or together in these registers. For more information, see the "[Error acknowledgment, dither switch-off and FrequencyPrescale](#)" on page 2521 registers.

Mode FrequencyPrescale

The unit is 1/10 or 1/100 Hz depending on how the "FrequencyPrescale" settings are configured.

| Data type | Value | Information |
|-----------|--------------|---|
| UINT | 0 | Disabled |
| | 1 to 99 | FrequencyPrescale 1/10: 10 Hz FrequencyPrescale 1/100: 1 Hz |
| | 100 to 65535 | FrequencyPrescale 1/10: 1/10 * Value = 10 to 6553.5 Hz FrequencyPrescale 1/100: 1/100 * Value = 1 to 655.35 Hz |

Mode SuperVibe

The unit is 1 Hz or 1/10 Hz depending on how the "FrequencyPrescale" settings are configured.

| Data type | Values | Information |
|-----------|----------------------------|---|
| UINT | 0 | Disabled |
| | 1 to 9 | FrequencyPrescale 1: 10 Hz FrequencyPrescale 1/10: 1 Hz |
| | 10 to 50000 10 to 65535 | FrequencyPrescale 1: 10 to 50000 Hz FrequencyPrescale 1/10: 1 to 6553.5 Hz |

9.25.2.13.4.10 Duty cycle

Name:

DutyCyclePWM01PWM02 (frequency mode 1)

DutyCyclePWM01 to DutyCyclePWM02 (frequency mode 2 and SuperVibe)

The duty cycle for the PWM outputs is set individually or separately depending on the frequency or SuperVibe mode.

For information about scaling, derating, etc. see the ["PWM pulse width" on page 2517](#) registers (PWM mode).

Notice!

A negative duty cycle can also be configured. In this case, the frequency is output to "PWM1/2" (identical to standard PWM/current mode) instead of the "PWM1/2+" output. It is especially important to take this into account with actuators that are only able to process positive input values.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.2.13.4.11 Dither amplitude

Name:

ConfigOutput01

This register can be used to configure the amplitude value or pulse width.

| Data type | Value | Information |
|-----------|----------|---|
| USINT | 0 to 255 | Current mode: 0 to 25.5% of the module's nominal current ¹⁾ PWM mode: 0 to 25.5% of the period duration. Bus controller default setting: 0 |

1) See the technical data for the module.

9.25.2.13.4.12 Dither frequency

Name:

ConfigOutput02

This register can be used to set the frequency in 2 Hz steps.

| Data type | Value | Information |
|-----------|----------|--|
| USINT | 0 to 255 | Corresponds to 0 to 510 Hz. Bus controller default setting: 0 |

9.25.2.13.5 Communication

9.25.2.13.5.1 Numerator

Name:

Counter01 to Counter02

This register indicates the status of counters 1 and 2. If counter 1 is configured as an ABR counter, then the register for counter 2 is assigned the current value of counter 1 when the reference pulse occurs.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.2.13.5.2 Input status

Name:

StatusInput01 to StatusInput04

CounterOverflow01 to CounterOverflow02

RefToggle01

The status of the inputs and counters is mapped in this register.

This function is available beginning with firmware Version 4.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-------------------|--------|---|
| 0 | StatusInput01 | 0 or 1 | Logical state of input 1 |
| ... | | ... | |
| 3 | StatusInput0 | 0 or 1 | Logical state of input 4 |
| 4 | CounterOverflow01 | 0 | Period duration or gate measurements of counter 1 are within the valid range (0x0 - 0xFFFF). The bit is only valid if overflow detection is enabled (bit 2 = 1 in the "Error acknowledgment, dither switch-off and FrequencyPrescale" on page 2521 register). |
| | | 1 | Overflow during period duration or gate measurement (reset with bit 2 = 0 in the "Error acknowledgment, dither switch-off and FrequencyPrescale" on page 2521 register). |
| 5 | CounterOverflow02 | 0 | Period duration or gate measurements of counter 2 are within the valid range (0x0 - 0xFFFF). The bit is only valid if overflow detection is enabled (bit 3 = 1 in the "Error acknowledgment, dither switch-off and FrequencyPrescale" on page 2521 register). |
| | | 1 | Overflow during period duration or gate measurement (reset with bit 3 = 0 in the "Error acknowledgment, dither switch-off and FrequencyPrescale" on page 2521 register). |
| 6 | RefToggle01 | x | Bit 6 changes value each time the counter state is latched from counter 1 to counter 2. After the module boots, bit 6 = 0. |
| 7 | Reserved | - | |

9.25.2.13.5.3 Temperature

Name:

Temperature01

The module temperature is displayed in this register.

| Data type | Value | Information |
|-----------|------------|--------------------------|
| SINT | -40 to 125 | Module temperature in °C |

9.25.2.13.5.4 Error status

Name:

UnderVoltageError

OverVoltageError

OvertemperatureError

OperatingError

CurrentError01 to CurrentError02

OverCurrentError01 to OverCurrentError02

If an error is detected, the corresponding error bit remains set in this register until the error is acknowledged (see ["Error acknowledgment, dither switch-off and FrequencyPrescale"](#) on page 2521).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|------------------------------|-------|---------------------------------|
| 0 | UnderVoltageError | 0 | No error |
| | | 1 | Module supply lower limit <18 V |
| 1 | OverVoltageError | 0 | No error |
| | | 1 | Module supply upper limit >50 V |
| 2 | OvertemperatureError | 0 | No error |
| | | 1 | Overtemperature |
| 3 | OperatingError ¹⁾ | 0 | No error |
| | | 1 | Faulty operation |
| 4 | CurrentError01 | 0 | No error |
| | | 1 | Open load error Output 1 |
| 5 | OverCurrentError01 | 0 | No error |
| | | 1 | Overcurrent error Output 1 |
| 6 | CurrentError02 | 0 | No error |
| | | 1 | Open load error Output 2 |
| 7 | OverCurrentError02 | 0 | No error |
| | | 1 | Overcurrent error Output 2 |

1) Firmware version 7.00 or higher.

Faulty operation

This warning indicates faulty operation of the module. The following table lists possible causes, the module's reaction and how to correct/acknowledge the error.

| Cause | Reaction | Correction/Acknowledgment |
|--|--|---|
| Default value for "PeriodDuration" on page 2516 or "Frequency" on page 2517 outside of specified range | Default value limited to the specified range | Automatic acknowledgment as soon as the default value is back within specifications |
| Later reconfiguration of the operating mode (see bits 2 to 3 of the "Module configuration" on page 2515 register) | The new configuration is ignored. The module continues to work in the original operating mode. | The original configuration is restored. |

Overcurrent error

An overcurrent error is reported when the current at the PWM output exceeds the set limit. For details, see ["Shutdown in the event of overcurrent"](#) on page 2508.

Open load error

An open load error is only registered in current control mode (see ["configuration register"](#) on page 2515) if the current setpoint is not reached. In some cases this can be caused by an open line, although usually the impedance of the load is too high.

9.25.2.13.5.5 Error acknowledgment, dither switch-off and FrequencyPrescale

Name:

ClearError01 to ClearError02

CounterOverflowDetectEnable01 to CounterOverflowDetectEnable02

CounterReset01 to CounterReset02

DitherDisable01 to DitherDisable02

FrequencyPrescale01 to FrequencyPrescale02

This register can be used to acknowledge errors; to enable/disable overflow detection, counters and dither; and to set a prescaler for the frequency domains.

This function is available beginning with firmware Version 4.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------------------------|-------|--|
| 0 | ClearError01 | 0 | No effect |
| | | 1 | Error acknowledgment on output 1 (overcurrent or open load) or acknowledgment from limit switch 1 |
| 1 | ClearError02 | 0 | No effect |
| | | 1 | Error acknowledgment on output 2 (overcurrent or open load) or acknowledgment from limit switch 2 |
| 2 | CounterOverflowDetectEnable01 | 0 | Overflow detection disabled. Bit 4 in the counter status register is reset (see "Input status" on page 2519) |
| | | 1 | Counter 1: Overflow detection enabled. |
| 3 | CounterOverflowDetectEnable02 | 0 | Overflow detection disabled. Bit 5 in the counter status register is reset (see "Input status" on page 2519) |
| | | 1 | Counter 2: Overflow detection enabled. |
| 4 | CounterReset01 | 0 | Counter 1 is enabled (default). |
| | | 1 | Counter 1 is set to 0 and disabled. If counter 1 is configured as an ABR counter (see "Counter configuration 1" on page 2514), then latch 2 is also set to 0. In this mode, the latched value from counter 1 is stored in counter 2. |
| 5 | CounterReset02 | 0 | Counter 2 is enabled (default). |
| | | 1 | Counter 2 is set to 0 and disabled (no effects if counter 1 is configured as an ABR counter) |
| 6 | DitherDisable01 | 0 | Dither for PWM output 1 is enabled (default). The dither frequency and dither amplitude must be >0 (see "Valve control" on page 2507). |
| | | 1 | Dither for PWM output 1 is disabled. |
| | FrequencyPrescale01 ¹⁾ | 0 | Unit in 1/10 or 1 Hz; depending on the operating mode |
| | | 1 | Unit in 1/100 or 1/10 Hz; depending on the operating mode |
| 7 | DitherDisable02 | 0 | Dither for PWM output 2 is enabled (default). The dither frequency and dither amplitude must be >0 (see "Valve control" on page 2507). |
| | | 1 | Dither for PWM output 2 is disabled. |
| | FrequencyPrescale02 ¹⁾ | 0 | Unit in 1/10 or 1 Hz; depending on the operating mode |
| | | 1 | Unit in 1/100 or 1/10 Hz; depending on the operating mode |

1) Firmware version 7.00 or higher.

FrequencyPrescale

Beginning with firmware version 7.00, bits 6 to 7 in the "Frequency mode 1 and 2" operating mode have a different meaning.

Instead of enabling/disabling dithering for channel 1 or 2, it toggles the prescaler for the frequency setting between:

- In the frequency mode
Unit in 1/10 Hz, frequency domain: 10 to 6553.5 Hz
Unit in 1/100 Hz, frequency domain: 1 to 655.35 Hz
- In the SuperVibe mode
Unit in 1 Hz, frequency domain: 10 to 50000 Hz
Unit in 1/10 Hz, frequency domain: 1 to 6553.5 Hz

In "Frequency mode 2" operating mode, only bit 6 (FrequencyPrescale01) is used since both channels are operated with the same frequency.

Information:

The frequency domain can be toggled at any time, but it also results in the frequency jumping by a factor of 10. If this frequency jump is not tolerated in the application, then the value set in the "Frequency" on page 2517 register must be adjusted accordingly.

9.25.2.13.6 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 250 μ s |

9.25.2.13.7 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 250 μ s |

9.25.3 X20MM3332

Data sheet version: 2.04

9.25.3.1 General information

The 3 outputs on the motor module are designed as full-bridge outputs. The continuous current per channel is 3 A at a peak current of up to 5 A. Integrated diagnostics offer the possibility to read back the output current for each channel using the application.

The module offers extensive possibilities for controlling motors, valves or resistive loads and is particularly well suited for controlling brush DC motors. Because the outputs are designed as full-bridge outputs, the motors can be moved in both directions.

- 3 full-bridge outputs (H-bridges)
- High component density
- 3 A continuous current
- 5 A peak current
- Readable current

9.25.3.2 Order data

| Model number | Short description | Figure |

9.25.3.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Color | Description |
|---|-------|--------|-----------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | e + r | | Red on / Green single flash | Invalid firmware |
| | 1 - 3 | Orange | On | The corresponding output is active |
| | | | Blinking | Error on the corresponding output |
| | | | Off | The corresponding output is switched off |

9.25.3.5 Pinout

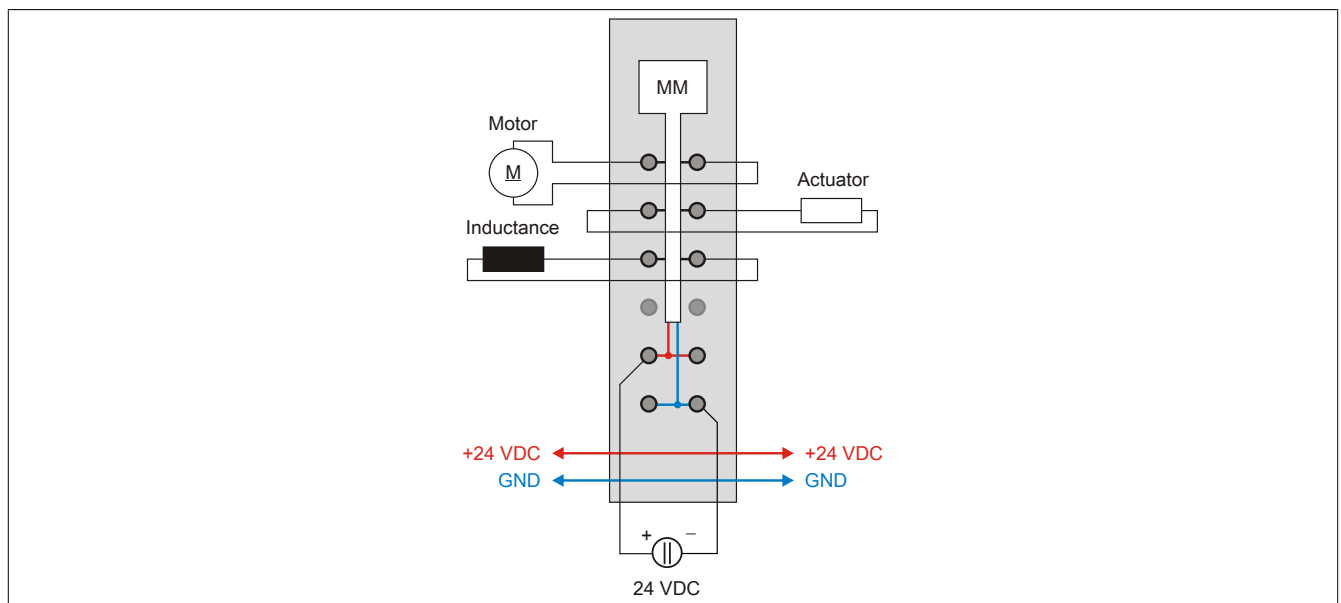

Lines with a cross section between a minimum of 0.75 mm² and a maximum of 2.5 mm² are recommended for the outputs.

Warning!

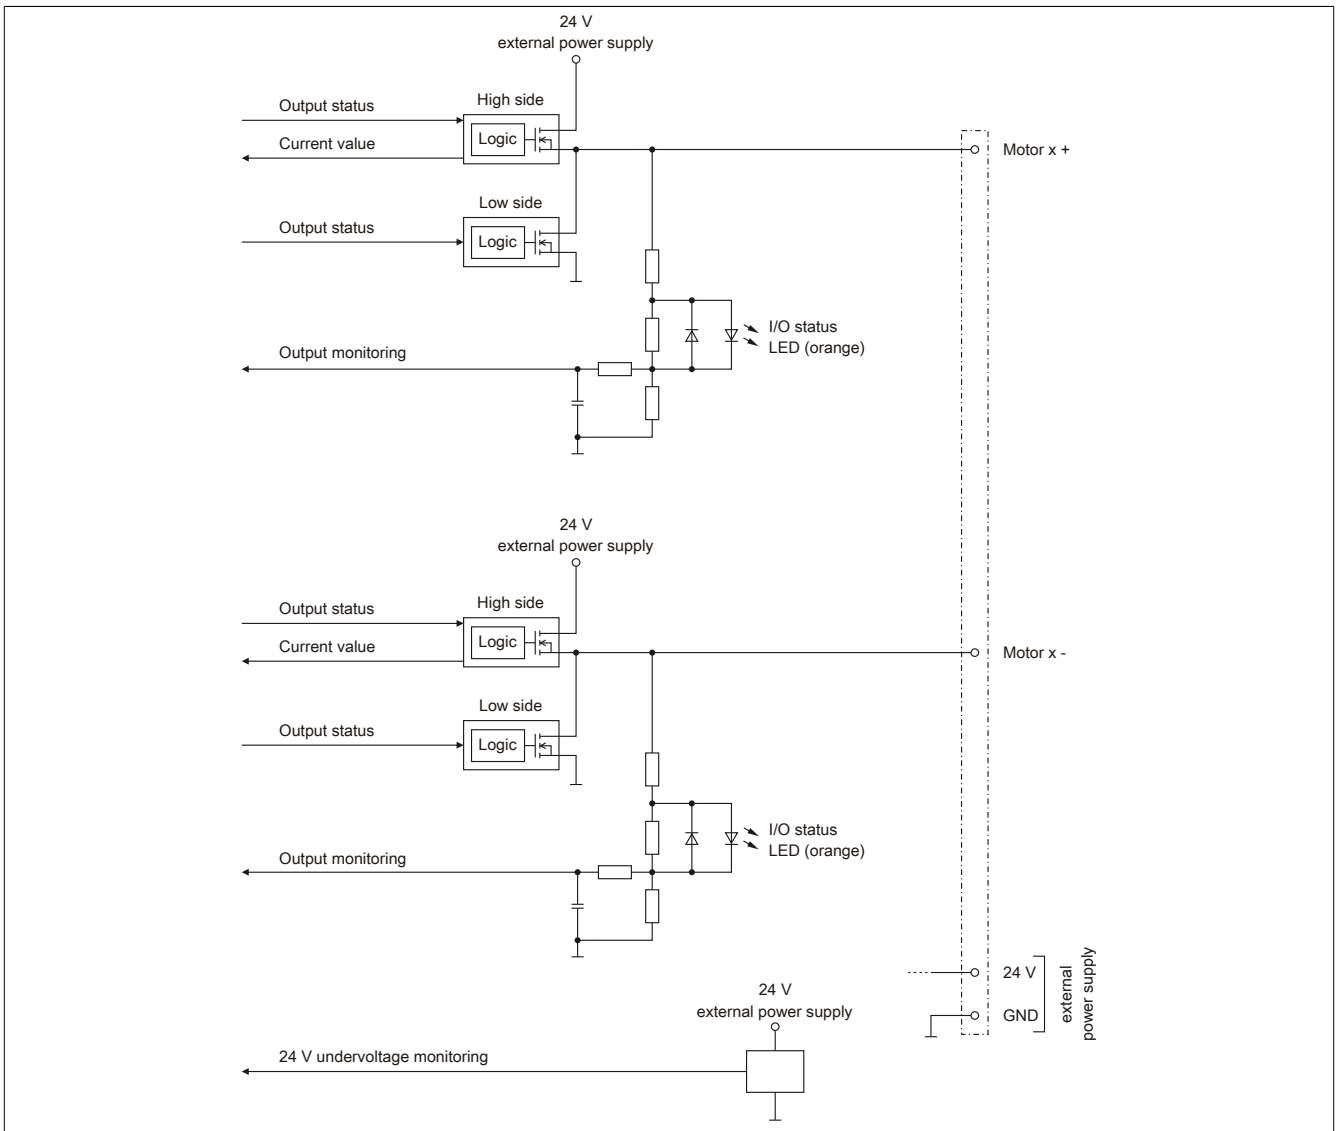

The terminal block is not permitted to be plugged in or unplugged during operation.

9.25.3.6 Connection example

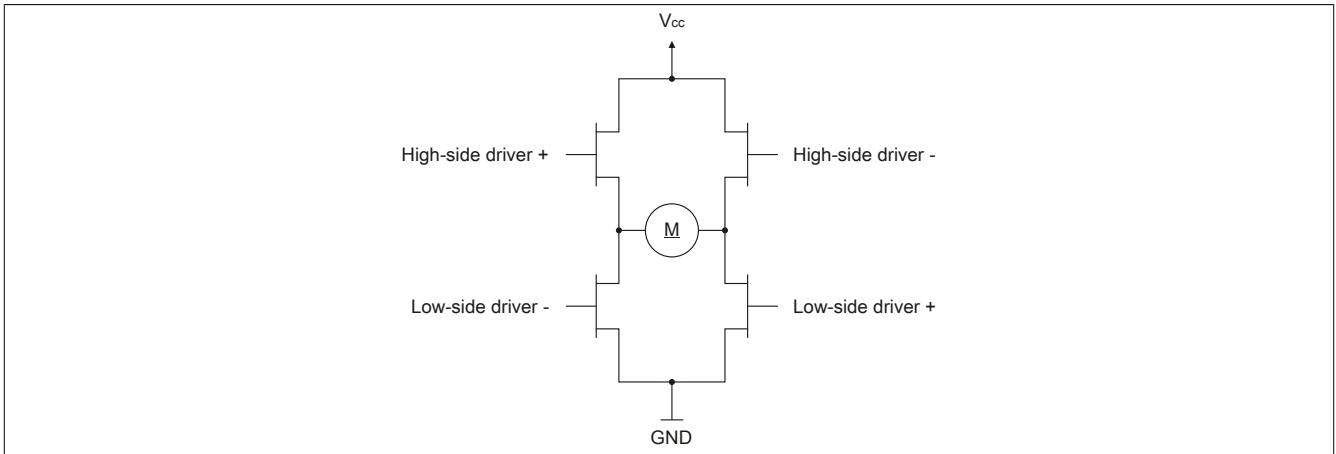

9.25.3.7 Output circuit diagram

9.25.3.8 Function description - Motor operation

Three DC motors can be operated with the module. Each output is designed as a full-bridge output, therefore the motors can be moved in both directions.

Description of the operating modes using the basic circuit diagram shown above:

| Operating mode | Description |
|------------------------|--|
| Rotational direction 1 | If the high-side driver + and the low-side driver + are active, the direction of rotation on the motor is from + to -. |
| Rotational direction 2 | If the high-side driver - and the low-side driver - are active, the direction of rotation on the motor is from - to +. |
| Brakes | If both low-side drivers are active, the motor is short-circuited. This functions as a motor brake. |

9.25.3.9 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load, but is always less than the sum of the output currents. Make sure that the maximum nominal current of 31 A per pin is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the power mains and the rated current of the overcurrent protection used are chosen according to the current load so that the maximum current load for the cable cross section selected (based on the type of layout, see table) is greater than or equal to the current load in the power mains. The rated current of the overcurrent protection must be less than or equal to the maximum current load for the cable cross section selected (based on the type of layout, see table):

$$I_{\text{Mains}} \leq I_{\text{Fuse}} \leq I_{\text{Line/cable}}$$

| Wire cross section [mm ²] | Current load of the cable cross section I_z / rated current of the over current protection I_b [A] according to type of installation in an ambient air temperature of 40°C in accordance to EN 60204-1 | | | |
|---------------------------------------|--|-----------|-----------|-----------|
| | B1 | B2 | C | E |
| 1.5 | 13.5 / 13 | 13.1 / 10 | 15.2 / 13 | 16.1 / 16 |
| 2.5 | 18.3 / 16 | 16.5 / 16 | 21 / 20 | 22 / 20 |
| 4 | 24 / 24 | 23 / 20 | 28 / 25 | 30 / 25 |
| 6 | 32 / 32 | 29 / 25 | 36 / 32 | 37 / 32 |

Table 494: Cable cross section of the mains supply line depending on the type of layout

The tripping current of the fuse cannot exceed the rated current of fuse I_b .

| Type of layout | Description |
|----------------|------------------------------------|
| B1 | Wires in conduit or cable duct |
| B2 | Cables in conduit or cable duct |
| C | Cables or wires on walls |
| E | Cables or wires on open cable tray |

Table 495: Type of layout for the mains supply line

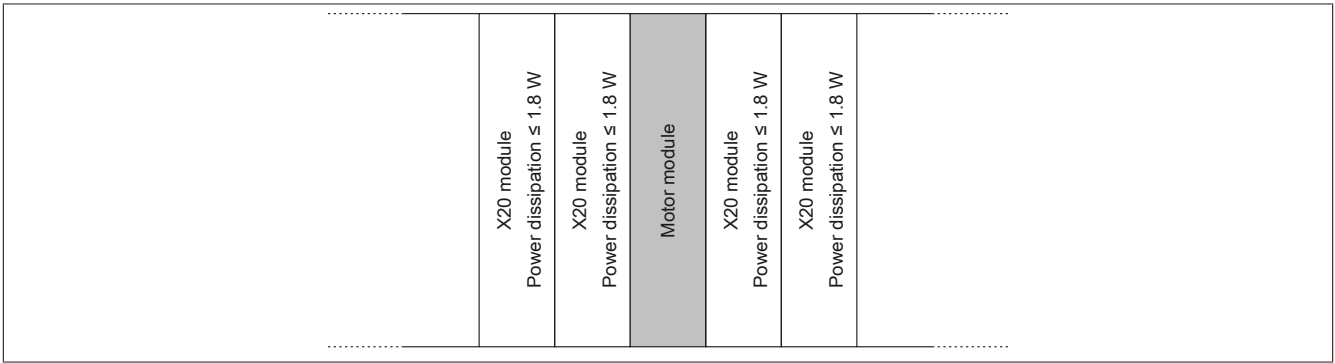

9.25.3.10 Derating

In order to be able to operate the motor module over the entire temperature range, only modules with a maximum power loss of 0.5 W can be installed next to the motor module or respective turn-off times must be implemented. If the neighboring modules have a higher power loss and all channels are operated continuously, the motor current must be derated.

When a motor is switched on, the current is increased for a short time. This behavior has no influence on the derating.

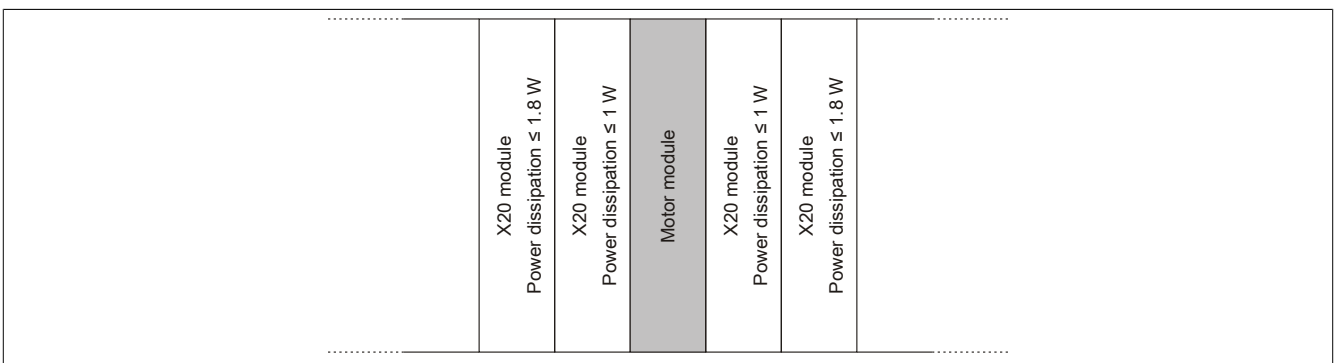

Current derating 1 of the motor module

Current derating for the motor module for neighboring modules with ≤ 1.8 W thermal power loss.

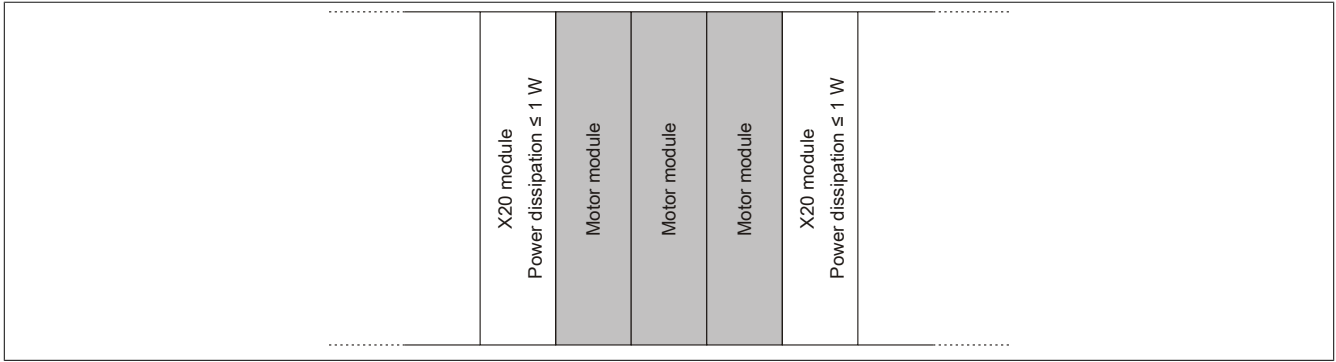

Current derating 2 of the motor module

Current derating for the motor module for neighboring modules with ≤ 1 W thermal power loss.

Current derating 3 of the motor module

Current derating with multiple motor modules next to each other.

9.25.3.11 Switching inductive loads (e.g. valves)

With enabled short circuit channel - All outputs with same load

With disabled short circuit channel - All outputs with same load

9.25.3.12 Monitoring the module supply

The module supply is continually monitored. If the supply voltage drops below 18V, all channels are switched off and an error bit is set.

Information:

The undervoltage must be present for longer than 250 ms, before all channels are switched off. Power dips can occur when starting motors or capacitive loads!

9.25.3.13 Monitoring the module current

The module current is continually monitored. If an overcurrent occurs, the respective channel is switched off and an error bit is set.

Information:

The overcurrent must be present for longer than 250 ms, before the channel is switched off. High starting currents occur when starting motors or capacitive loads!

9.25.3.14 Channel monitoring

After each switching process, the status inputs are checked with a 2 ms delay to ensure they are correct. This is done so that faulty status signals are not generated when switching motors or capacitive loads.

If the status of the output does not correspond to the status that is expected (e.g. short circuit or motor spin-out), a warning bit is set.

Information:

When channel monitoring is triggered, a warning is given. The output remains switched even if there is a short circuit and is cycled to the output by the internal protective circuit.

If the motor is still spinning out, the voltage drops slowly. That means the warning bit "[StatusDigitalOutput](#)" on page 2537 can show a warning while the motor is spinning out.

If the motor is moved externally, voltage is induced into the module, which results in `StatusDigitalOutput` being set and the red LED being lit (warning).

9.25.3.15 Shutdown in the event of overtemperature (starting at 85°C)

If the module temperature reaches or overshoots the limit value of 85°C, the module performs the following actions:

- Sets the "overtemperature" error bit
- Cuts off the outputs (short-circuited)

As soon as the temperature is reduced below 85°C again, the error must be acknowledged with "OvertemperatureAcknowledge" so that the channels can be switched on again.

9.25.3.16 Register description

9.25.3.16.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

9.25.3.16.2 Function model 0 - Standard

In this function model, control of full bridges takes place using 3 bits per channel.

| Register | Name | Data type | Read | | Write | |
|----------------------|---|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |
| 0 | Motor configuration 1 - Default | USINT | | | • | |
| | StartChannel01 | Bit 0 | | | | |
| | ShortCircuitChannel01 | Bit 1 | | | | |
| | DirectionChannel01 | Bit 2 | | | | |
| | StartChannel02 | Bit 4 | | | | |
| | ShortCircuitChannel02 | Bit 5 | | | | |
| | DirectionChannel02 | Bit 6 | | | | |
| 1 | Motor configuration 2 - Default | USINT | | | • | |
| | StartChannel03 | Bit 0 | | | | |
| | ShortCircuitChannel03 | Bit 1 | | | | |
| | DirectionChannel03 | Bit 2 | | | | |
| 18 | Error acknowledged | USINT | | | • | |
| | OvercurrentAcknowledge01 | Bit 0 | | | | |
| | OvercurrentAcknowledge02 | Bit 1 | | | | |
| | OvercurrentAcknowledge03 | Bit 2 | | | | |
| | OvertemperatureAcknowledge | Bit 6 | | | | |
| | UndervoltageAcknowledge | Bit 7 | | | | |
| Communication | | | | | | |
| 4 | CurrentInput01 | USINT | • | | | |
| 6 | CurrentInput02 | USINT | • | | | |
| 8 | CurrentInput03 | USINT | • | | | |
| 20 | Module and channel status | USINT | • | | | |
| | OvercurrentError01 | Bit 0 | | | | |
| | OvercurrentError02 | Bit 1 | | | | |
| | OvercurrentError03 | Bit 2 | | | | |
| | StatusDigitalOutput01 | Bit 3 | | | | |
| | StatusDigitalOutput02 | Bit 4 | | | | |
| | StatusDigitalOutput03 | Bit 5 | | | | |
| | OvertemperatureError | Bit 6 | | | | |
| | UndervoltageError | Bit 7 | | | | |

9.25.3.16.3 Function model 1 - Byte control and Function model 254 - bus controller

Control of the half bridges takes place using one byte (two bits per channel). All other registers are the same as in [Function model 0 - Standard](#).

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------------------|----------------------|--|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | | |
| 0 | 0 | Motor configuration - Byte control | USINT | | | • | |
| 18 | 4 | Error acknowledged | USINT | | | • | |
| | | OvercurrentAcknowledge01 | Bit 0 | | | | |
| | | OvercurrentAcknowledge02 | Bit 1 | | | | |
| | | OvercurrentAcknowledge03 | Bit 2 | | | | |
| | | OvertemperatureAcknowledge | Bit 6 | | | | |
| | | UndervoltageAcknowledge | Bit 7 | | | | |
| Communication | | | | | | | |
| 4 | 0 | CurrentInput01 | USINT | • | | | |
| 6 | 2 | CurrentInput02 | USINT | • | | | |
| 8 | 4 | CurrentInput03 | USINT | • | | | |
| 20 | 6 | Module and channel status | USINT | • | | | |
| | | OvercurrentError01 | Bit 0 | | | | |
| | | OvercurrentError02 | Bit 1 | | | | |
| | | OvercurrentError03 | Bit 2 | | | | |
| | | StatusDigitalOutput01 | Bit 3 | | | | |
| | | StatusDigitalOutput02 | Bit 4 | | | | |
| | | StatusDigitalOutput03 | Bit 5 | | | | |
| | | OvertemperatureError | Bit 6 | | | | |
| | | UndervoltageError | Bit 7 | | | | |

1) The offset specifies the position of the register within the CAN object.

9.25.3.16.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.25.3.16.3.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.25.3.16.4 Configuration

9.25.3.16.4.1 Motor configuration 1 - Default

Name:

StartChannel01 to StartChannel02

ShortCircuitChannel01 to ShortCircuitChannel02

DirectionChannel01 to DirectionChannel02

This register contains the control bits for the first two channels.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-----|-----------------------|---|--|
| 0 | StartChannel01 | 0 | Switch off channel 1 |
| | | 1 | Channel 1 is started (bridge control) |
| 1 | ShortCircuitChannel01 | 0 | Do not short circuit channel 1. |
| | | 1 | Short circuit channel 1. |
| 2 | DirectionChannel01 | 0 | Rotational direction 1 |
| | | 1 | Rotational direction 2: The polarity of the connections for motor 1 are reversed internally. ¹⁾ |
| 3 | Reserved | - | Reserved |
| 4 | StartChannel02 | 0 | Switch off channel 2 |
| | | 1 | Channel 2 is started (bridge control) |
| 5 | ShortCircuitChannel02 | 0 | Do not short circuit channel 2. |
| | | 1 | Short circuit channel 2. |
| 6 | DirectionChannel02 | 0 | Rotational direction 1 |
| | | 1 | Rotational direction 2: The polarity of the connections for motor 2 are reversed internally. ¹⁾ |
| 7 | Reserved | - | |

1) The direction of rotation on the motor is changed by internally reversing the polarity of the connections.

Information:

StartChannel 1 to 2 and ShortCircuitChannel 1 to 2:

To avoid internal bridge shorts, the outputs are delayed by 200 µs when switching to another state or a short circuit.

Information:

When the direction of the motor is changed, the polarity is reversed. If the direction of rotation on the motor is changed during operation, the motor immediately brakes and turns in the other direction. This can result in very high current values. Therefore, we recommend short-circuiting the motor first (braking) and then changing to the other direction.

9.25.3.16.4.2 Motor configuration 2 - Default

Name:

StartChannel03

ShortCircuitChannel03

DirectionChannel03

This register contains the control bits for the third channel.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-------|-----------------------|---|--|
| 0 | StartChannel03 | 0 | Switch off channel 3 |
| | | 1 | Switch on channel 3 |
| 1 | ShortCircuitChannel03 | 0 | Do not short circuit channel 3. |
| | | 1 | Short circuit channel 3. |
| 2 | DirectionChannel03 | 0 | Rotational direction 1 |
| | | 1 | Rotational direction 2: The polarity of the connections for motor 3 are reversed internally. ¹⁾ |
| 3 - 7 | Reserved | - | |

1) The direction of rotation on the motor is changed by internally reversing the polarity of the connections.

Information:

StartChannel 3 and ShortCircuitChannel 3:

To avoid internal bridge shorts, the outputs are delayed by 200 µs when switching to another state or a short circuit.

Information:

When the direction of the motor is changed, the polarity is reversed. If the direction of rotation on the motor is changed during operation, the motor immediately brakes and turns in the other direction. This can result in very high current values. Therefore, we recommend short-circuiting the motor first (braking) and then changing to the other direction.

9.25.3.16.4.3 Motor configuration - Byte control

Name:

ControlByte01

This register is used to control all 3 channels. Two bits per channels are always grouped together. This register is only used in [Function model 1 - Byte control](#) and [Function model 254 - bus controller](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-------|-----------|-----|--|
| 0 - 1 | Channel 1 | 00 | No-load operation |
| | | 01 | Rotational direction 1 |
| | | 10 | Rotational direction 2: The polarity of the connections for motor 1 are reversed internally. ¹⁾ |
| | | 11 | Short circuit |
| ... | | ... | |
| 4 - 5 | Channel 3 | 00 | No-load operation |
| | | 01 | Rotational direction 1 |
| | | 10 | Rotational direction 2: The polarity of the connections for motor 3 are reversed internally. ¹⁾ |
| | | 11 | Short circuit |
| 6 - 7 | Reserved | - | |

1) The direction of rotation on the motor is changed by internally reversing the polarity of the connections.

Information:

When the direction of the motor is changed, the polarity is reversed. If the direction of rotation on the motor is changed during operation, the motor immediately brakes and turns in the other direction. This can result in very high current values. Therefore, we recommend short-circuiting the motor first (braking) and then changing to the other direction.

9.25.3.16.4.4 Error acknowledged

Name:

OvercurrentAcknowledge01 to OvercurrentAcknowledge03

OvertemperatureAcknowledge

UndervoltageAcknowledge

This register contains bits used to acknowledge an overcurrent error, an undervoltage error and an overtemperature error.

The errors are acknowledged with a rising edge. An existing error can only be acknowledged if the cause of the error has been corrected.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-------|----------------------------|---|---|
| 0 | OvercurrentAcknowledge01 | 1 | With a rising edge, the overcurrent error shown on channel 1 is acknowledged. |
| 1 | OvercurrentAcknowledge02 | 1 | With a rising edge, the overcurrent error shown on channel 2 is acknowledged. |
| 2 | OvercurrentAcknowledge03 | 1 | With a rising edge, the overcurrent error shown on channel 3 is acknowledged. |
| 3 - 5 | Reserved | - | |
| 6 | OvertemperatureAcknowledge | 1 | With a rising edge, the overtemperature error shown is acknowledged. |
| 7 | UndervoltageAcknowledge | 1 | With a rising edge, the undervoltage error shown is acknowledged. |

9.25.3.16.5 Communication**9.25.3.16.5.1 Voltage of the channels**

Name:

CurrentInput01 to CurrentInput03

Every 700 μ s, the current that flows through a channel is measured with a resolution of 8 bits. The value measured is stored in these registers.

| Data type | Value | Information |
|-----------|----------|-------------|
| USINT | 0 to 255 | 0 to 5 A |

9.25.3.16.5.2 Module and channel status

Name:

OvercurrentError01 to OvercurrentError03
 StatusDigitalOutput01 to StatusDigitalOutput03
 OvertemperatureError
 UndervoltageError

Some operating states are monitored by the module. They are:

- "Module supply" on page 2531
- "Module current" on page 2531
- "Status channels" on page 2531
- "Module temperature" on page 2531

The states are stored in this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-----|-----------------------|---|--|
| 0 | OvercurrentError01 | 0 | No overcurrent on channel 1 |
| | | 1 | Overcurrent on channel 1 |
| 1 | OvercurrentError02 | 0 | No overcurrent on channel 2 |
| | | 1 | Overcurrent on channel 2 |
| 2 | OvercurrentError03 | 0 | No overcurrent on channel 3 |
| | | 1 | Overcurrent on channel 3 |
| 3 | StatusDigitalOutput01 | 0 | Channel 1 output status OK |
| | | 1 | Channel 1 output warning: Short-circuit or invalid output status |
| 4 | StatusDigitalOutput02 | 0 | Channel 2 output status OK |
| | | 1 | Channel 2 output warning: Short-circuit or invalid output status |
| 5 | StatusDigitalOutput03 | 0 | Channel 3 output status OK |
| | | 1 | Channel 3 output warning: Short-circuit or invalid output status |
| 6 | OvertemperatureError | 0 | Module temperature within permitted range |
| | | 1 | Module overtemperature error |
| 7 | UndervoltageError | 0 | Supply voltage within permitted range |
| | | 1 | Supply voltage has dropped below 18V |

9.25.3.16.6 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 400 μ s |

9.25.3.16.7 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 400 μ s |

9.25.4 X20MM4331

Data sheet version: 2.04

9.25.4.1 General information

The 4 outputs on the motor module are designed as half-bridge outputs. The continuous current per channel is 3 A at a peak current of up to 5 A. Integrated diagnostics offer the possibility to read back the output current for each channel using the application.

The module offers extensive possibilities for controlling motors, valves or resistive loads and is particularly well suited for controlling brush DC motors. The outputs can be switched on/off and short-circuited.

- 4 half-bridge outputs
- High component density
- 3 A continuous current
- 5 A peak current
- Readable current

9.25.4.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|--------|-----------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Off | RESET mode |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | e + r | | Red on / Green single flash | Invalid firmware |
| | 1 - 4 | Orange | On | The corresponding output is active |
| | | | Blinking | Error on the corresponding output |
| | | | Off | The corresponding output is switched off |

9.25.4.5 Pinout

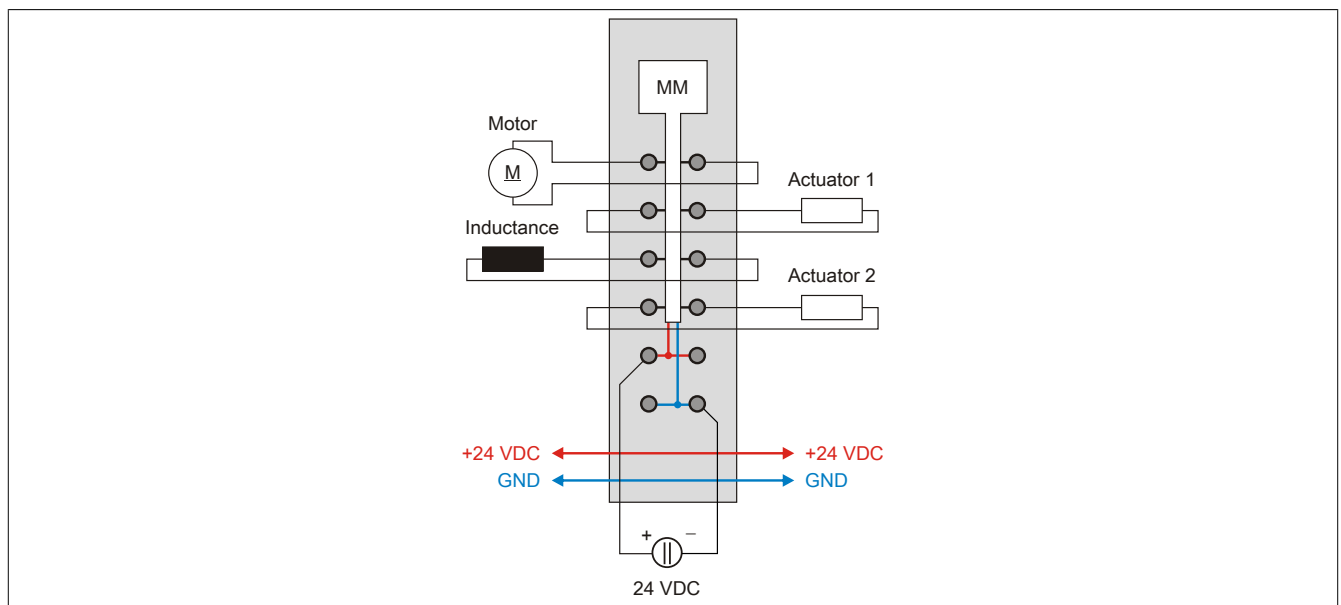

Lines with a cross section between a minimum of 0.75 mm² and a maximum of 2.5 mm² are recommended for the outputs.

Warning!

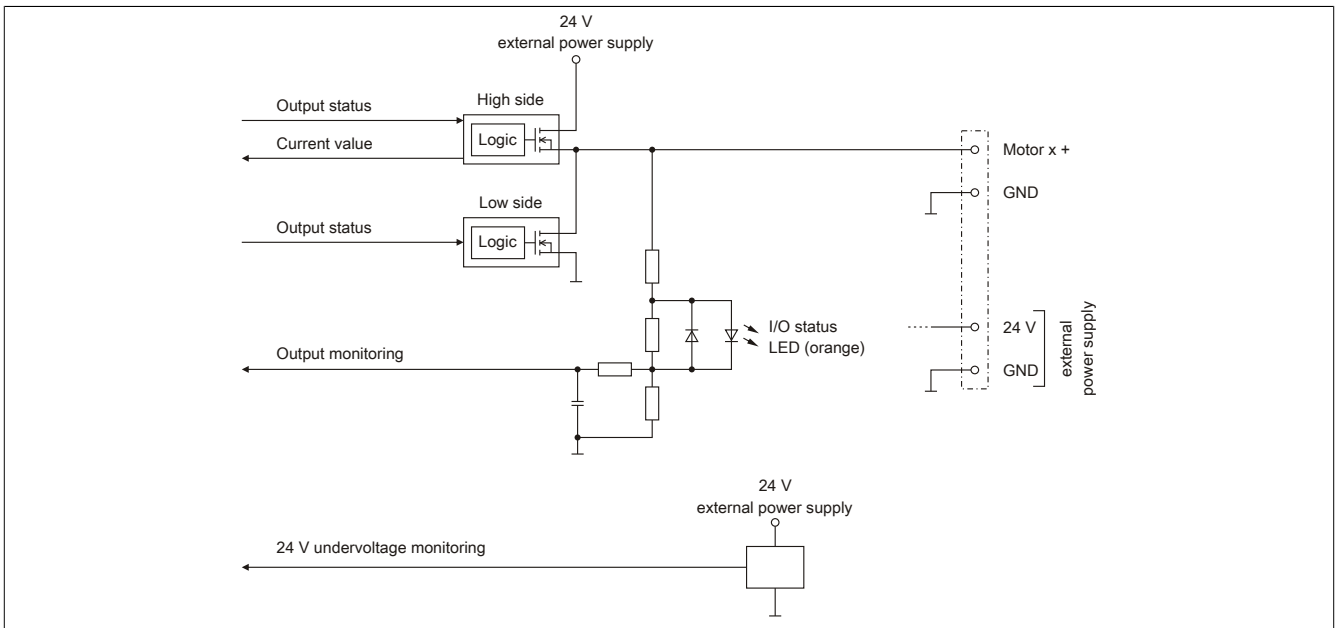

The terminal block is not permitted to be plugged in or unplugged during operation.

9.25.4.6 Connection example

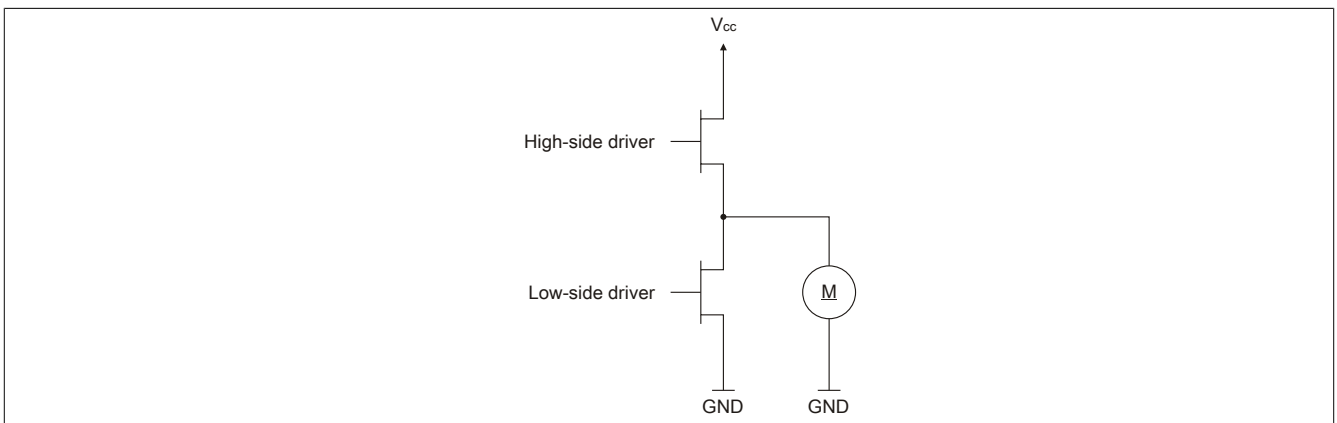

9.25.4.7 Output circuit diagram

9.25.4.8 Function description - Motor operation

Four DC motors can be operated with the module. Each output is designed as a half-bridge.

Description of the operating modes using the basic circuit diagram shown above:

| Operating mode | Description |
|------------------|--|
| Motor is running | If the high-side driver is active, the motor is switched on. |
| Brakes | If motor braking should take place, the high-side driver is first switched off and then the low-side driver is activated. In this way, the motor windings are short-circuited and the motor braking takes place. |

9.25.4.9 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load, but is always less than the sum of the output currents. Make sure that the maximum nominal current of 31 A per pin is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the power mains and the rated current of the overcurrent protection used are chosen according to the current load so that the maximum current load for the cable cross section selected (based on the type of layout, see table) is greater than or equal to the current load in the power mains. The rated current of the overcurrent protection must be less than or equal to the maximum current load for the cable cross section selected (based on the type of layout, see table):

$$I_{\text{Mains}} \leq I_{\text{Fuse}} \leq I_{\text{Line/cable}}$$

| Wire cross section [mm ²] | Current load of the cable cross section I_z / rated current of the over current protection I_b [A] according to type of installation in an ambient air temperature of 40°C in accordance to EN 60204-1 | | | |
|---------------------------------------|--|-----------|-----------|-----------|
| | B1 | B2 | C | E |
| 1.5 | 13.5 / 13 | 13.1 / 10 | 15.2 / 13 | 16.1 / 16 |
| 2.5 | 18.3 / 16 | 16.5 / 16 | 21 / 20 | 22 / 20 |
| 4 | 24 / 24 | 23 / 20 | 28 / 25 | 30 / 25 |
| 6 | 32 / 32 | 29 / 25 | 36 / 32 | 37 / 32 |

Table 498: Cable cross section of the mains supply line depending on the type of layout

The tripping current of the fuse cannot exceed the rated current of fuse I_b .

| Type of layout | Description |
|----------------|------------------------------------|
| B1 | Wires in conduit or cable duct |
| B2 | Cables in conduit or cable duct |
| C | Cables or wires on walls |
| E | Cables or wires on open cable tray |

Table 499: Type of layout for the mains supply line

9.25.4.10 Derating

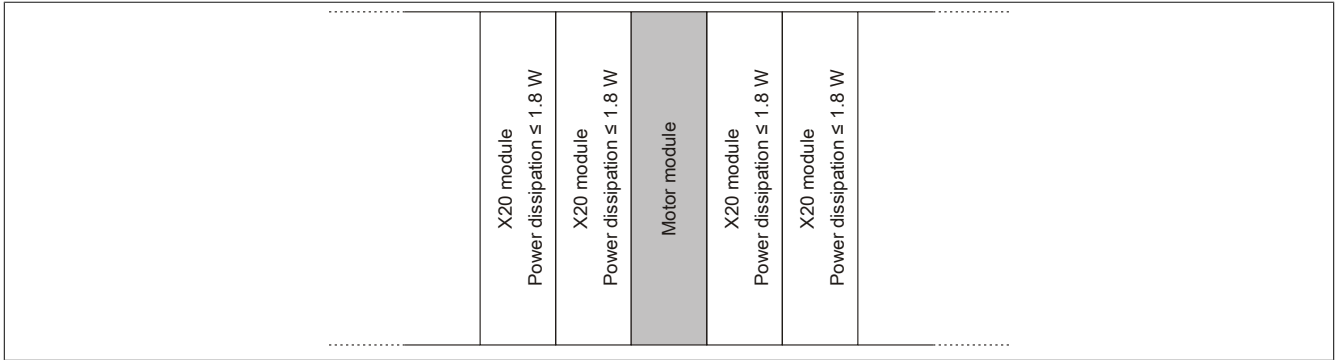

In order to be able to operate the motor module over the entire temperature range, only modules with a maximum power loss of 0.5 W can be installed next to the motor module or respective turn-off times must be implemented.

If the neighboring modules have a higher power loss and all channels are operated continuously, the motor current must be derated.

When a motor is switched on, the current is increased for a short time. This behavior has no influence on the derating.

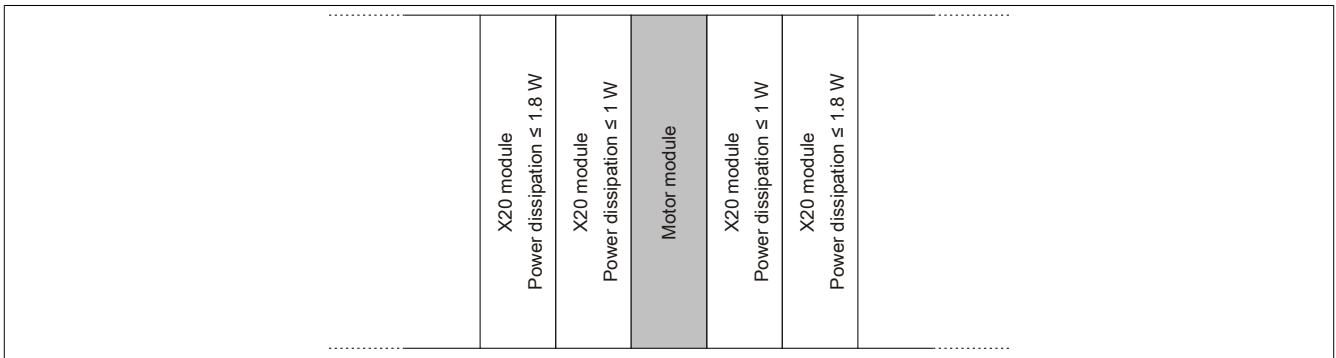

Current derating 1 of the motor module

Current derating for the motor module for neighboring modules with ≤ 1.8 W thermal power loss.

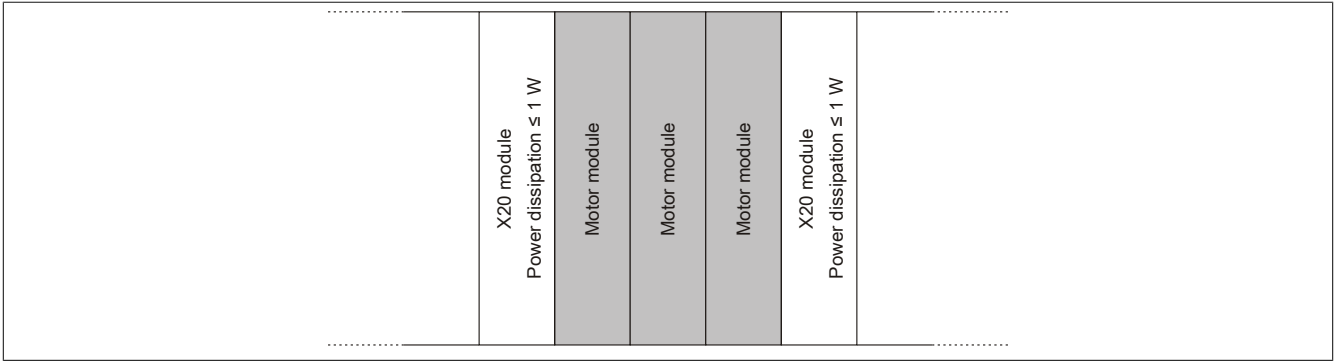

Current derating 2 of the motor module

Current derating for the motor module for neighboring modules with ≤ 1 W thermal power loss.

Current derating 3 of the motor module

Current derating with multiple motor modules next to each other.

9.25.4.11 Switching inductive loads (e.g. valves)

All outputs with the same load.

9.25.4.12 Monitoring the module supply

The module supply is continually monitored. If the supply voltage drops below 18V, all channels are switched off and an error bit is set.

Information:

The undervoltage must be present for longer than 250 ms, before all channels are switched off. Power dips can occur when starting motors or capacitive loads!

9.25.4.13 Monitoring the module current

The module current is continually monitored. If an overcurrent occurs, the respective channel is switched off and an error bit is set.

Information:

The overcurrent must be present for longer than 250 ms, before the channel is switched off. High starting currents occur when starting motors or capacitive loads!

9.25.4.14 Channel monitoring

After each switching process, the status inputs are checked with a 2 ms delay to ensure they are correct. This is done so that faulty status signals are not generated when switching motors or capacitive loads.

If the status of the output does not correspond to the status that is expected (e.g. short circuit or motor spin-out), a warning bit is set.

Information:

When channel monitoring is triggered, a warning is given. The output remains switched even if there is a short circuit and is cycled to the output by the internal protective circuit.

If the motor is still spinning out, the voltage drops slowly. That means the warning bit "[StatusDigitalOutput](#)" on page 2549 can show a warning while the motor is spinning out.

If the motor is moved externally, voltage is induced into the module, which results in `StatusDigitalOutput` being set and the red LED being lit (warning).

9.25.4.15 Shutdown in the event of overtemperature (starting at 85°C)

If the module temperature reaches or overshoots the limit value of 85°C, the module performs the following actions:

- Sets the "overtemperature" error bit
- Cuts off the outputs (short-circuited)

As soon as the temperature is reduced below 85°C again, the error must be acknowledged with "OvertemperatureAcknowledge" so that the channels can be switched on again.

9.25.4.16 Register description

9.25.4.16.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.25.4.16.2 Function model 0 - Standard

In this function model, control of full bridges takes place using 3 bits per channel.

| Register | Name | Data type | Read | | Write | |
|----------------------|-----------------------------------|-----------|--------|---------|--------|---------|
| | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | |
| 0 | Motor configuration - Default | USINT | | | • | |
| | StartChannel01 | Bit 0 | | | | |
| | ShortCircuitChannel01 | Bit 1 | | | | |
| | StartChannel02 | Bit 2 | | | | |
| | ShortCircuitChannel02 | Bit 3 | | | | |
| | StartChannel03 | Bit 4 | | | | |
| | ShortCircuitChannel03 | Bit 5 | | | | |
| | StartChannel04 | Bit 6 | | | | |
| 18 | Error acknowledged | USINT | | | • | |
| | OvercurrentAcknowledge01 | Bit 0 | | | | |
| | ... | ... | | | | |
| | OvercurrentAcknowledge04 | Bit 3 | | | | |
| | OvertemperatureAcknowledge | Bit 5 | | | | |
| | UndervoltageAcknowledge | Bit 6 | | | | |
| Communication | | | | | | |
| 2 + N * 2 | CurrentInput0N (Index N = 1 to 4) | USINT | • | | | |
| 20 | Status of current and channels | USINT | • | | | |
| | OvercurrentError01 | Bit 0 | | | | |
| | ... | ... | | | | |
| | OvercurrentError04 | Bit 3 | | | | |
| | StatusDigitalOutput01 | Bit 4 | | | | |
| | ... | ... | | | | |
| 21 | StatusDigitalOutput04 | Bit 7 | | | | |
| | Module status | USINT | • | | | |
| | OvertemperatureError | Bit 0 | | | | |
| | UndervoltageError | Bit 1 | | | | |

9.25.4.16.3 Function model 1 - Byte control and Function model 254 - bus controller

Control of the half bridges takes place using one byte (two bits per channel). All other registers are the same as in [Function model 0 - Standard](#).

| Register | Offset ¹⁾ | Name | Data type | Read | | Write | |
|----------------------|----------------------|------------------------------------|-----------|--------|---------|--------|---------|
| | | | | Cyclic | Acyclic | Cyclic | Acyclic |
| Configuration | | | | | | | |
| 0 | 0 | Motor configuration - Byte control | USINT | | | • | |
| 18 | 12 | Error acknowledged | USINT | | | • | |
| | | OvercurrentAcknowledge01 | Bit 0 | | | | |
| | | ... | ... | | | | |
| | | OvercurrentAcknowledge04 | Bit 3 | | | | |
| | | OvertemperatureAcknowledge | Bit 5 | | | | |
| | | UndervoltageAcknowledge | Bit 6 | | | | |
| Communication | | | | | | | |
| $2 + N * 2$ | $2 + N * 2$ | CurrentInput0N (Index N = 1 to 4) | USINT | • | | | |
| 20 | 8 | Status of current and channels | USINT | • | | | |
| | | OvercurrentError01 | Bit 0 | | | | |
| | | ... | ... | | | | |
| | | OvercurrentError04 | Bit 3 | | | | |
| | | StatusDigitalOutput01 | Bit 4 | | | | |
| | | ... | ... | | | | |
| | | StatusDigitalOutput04 | Bit 7 | | | | |
| 21 | 10 | Module status | USINT | • | | | |
| | | OvertemperatureError | Bit 0 | | | | |
| | | UndervoltageError | Bit 1 | | | | |

1) The offset specifies the position of the register within the CAN object.

9.25.4.16.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.25.4.16.3.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.25.4.16.4 Configuration

9.25.4.16.4.1 Motor configuration - Default

Name:

StartChannel01 to StartChannel04

ShortCircuitChannel01 to ShortCircuitChannel04

This register contains the control bits for all channels.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-----|-----------------------|---|---------------------------------------|
| 0 | StartChannel01 | 0 | Switch off channel 1 |
| | | 1 | Channel 1 is started (bridge control) |
| 1 | ShortCircuitChannel01 | 0 | Do not short circuit channel 1. |
| | | 1 | Short circuit channel 1. |
| 2 | StartChannel02 | 0 | Switch off channel 2 |
| | | 1 | Channel 2 is started (bridge control) |
| 3 | ShortCircuitChannel02 | 0 | Do not short circuit channel 2. |
| | | 1 | Short circuit channel 2. |
| 4 | StartChannel03 | 0 | Switch off channel 3 |
| | | 1 | Channel 3 is started (bridge control) |
| 5 | ShortCircuitChannel03 | 0 | Do not short circuit channel 3. |
| | | 1 | Short circuit channel 3. |
| 6 | StartChannel04 | 0 | Switch off channel 4 |
| | | 1 | Channel 4 is started (bridge control) |
| 7 | ShortCircuitChannel04 | 0 | Do not short circuit channel 4. |
| | | 1 | Short circuit channel 4. |

Information:

To avoid internal bridge shorts, the outputs are delayed by 200 µs when switching to another state or a short circuit.

9.25.4.16.4.2 Motor configuration - Byte control

Name:

ControlByte01

This register is used to control all four channels. Two bits per channels are always grouped together. This register is only used in [Function model 1 - Byte control](#) and [Function model 254 - bus controller](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-------|-----------|-----|---------------|
| 0 - 1 | Channel 1 | 00 | Off |
| | | 01 | On |
| | | 10 | Off |
| | | 11 | Short circuit |
| ... | | ... | |
| 6 - 7 | Channel 4 | 00 | Off |
| | | 01 | On |
| | | 10 | Off |
| | | 11 | Short circuit |

9.25.4.16.4.3 Error acknowledged

Name:

OvercurrentAcknowledge01 to OvercurrentAcknowledge04
OvertemperatureAcknowledge
UndervoltageAcknowledge

This register contains bits used to acknowledge an overcurrent error, an undervoltage error and an overtemperature error.

The errors are acknowledged with a rising edge. An existing error can only be acknowledged if the cause of the error has been corrected.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-------|----------------------------|-----|---|
| 0 | OvercurrentAcknowledge01 | 1 | With a rising edge, the overcurrent error shown on channel 1 is acknowledged. |
| ... | | ... | |
| 3 | OvercurrentAcknowledge04 | 1 | With a rising edge, the overcurrent error shown on channel 4 is acknowledged. |
| 4 - 5 | Reserved | - | |
| 6 | OvertemperatureAcknowledge | 1 | With a rising edge, the overtemperature error shown is acknowledged. |
| 7 | UndervoltageAcknowledge | 1 | With a rising edge, the undervoltage error shown is acknowledged. |

9.25.4.16.5 Communication

9.25.4.16.5.1 Voltage of the channels

Name:

CurrentInput01 to CurrentInput04

Every 500 μ s, the current that flows through a channel is measured with a resolution of 8 bits. The value measured is stored in these registers.

| Data type | Value | Information |
|-----------|----------|-------------|
| USINT | 0 to 255 | 0 to 5 A |

9.25.4.16.5.2 Status of current and channels

Name:

OvercurrentError01 to OvercurrentError04
StatusDigitalOutput01 to StatusDigitalOutput04

Some operating states are monitored by the module. They are:

- ["Module current" on page 2545](#)
- ["Status channels" on page 2545](#)

The states are stored in this register. For other operating modes, see ["Module status" on page 2550](#)

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-----|-----------------------|-----|--|
| 0 | OvercurrentError0 | 0 | No overcurrent on channel 1 |
| | | 1 | Overcurrent on channel 1 |
| ... | | ... | |
| 3 | OvercurrentError04 | 0 | No overcurrent on channel 4 |
| | | 1 | Overcurrent on channel 4 |
| 4 | StatusDigitalOutput01 | 0 | Channel 1 output status OK |
| | | 1 | Channel 1 output warning: Short-circuit or invalid output status |
| ... | | ... | |
| 7 | StatusDigitalOutput04 | 0 | Channel 4 output status OK |
| | | 1 | Channel 4 output warning: Short-circuit or invalid output status |

9.25.4.16.5.3 Module status

Name:

OvertemperatureError

UndervoltageError

Some operating states are monitored by the module. They are:

- ["Module supply" on page 2545](#)
- ["Module temperature" on page 2545](#)

The states are stored in this register. For other operating modes, see ["Status of current and channels" on page 2549](#)

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | | | Description |
|-------|----------------------|---|---|
| 0 | OvertemperatureError | 0 | Module temperature within permitted range |
| | | 1 | Module overtemperature error |
| 1 | UndervoltageError | 0 | Supply voltage within permitted range |
| | | 1 | Supply voltage has dropped below 18V |
| 2 - 7 | Reserved | - | |

9.25.4.16.6 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 400 μ s |

9.25.4.16.7 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time |
|-------------------------|
| 400 μ s |

9.25.5 X20MM4455

Data sheet version: 1.21

9.25.5.1 General information

The PWM motor bridge module is used to control 4 DC motors with a nominal voltage of 24 to 48 VDC $\pm 25\%$ at a nominal current up to 6 A. The module can be reconfigured and used in current controller mode for controlling inductive loads. The module is also equipped with 12 digital inputs, which can be used as incremental counters. The 4 motors are controlled with a full-bridge (H-bridge). This enables the motors to be moved in both directions.

- 4x outputs (H bridge) with PWM control and 24 to 48 VDC $\pm 25\%$ supply
- 6 A nominal current (10 A max. current)
- 15 Hz to 50 kHz frequency, 16-bit
- PWM resolution, 15-bit + sign, minimum 10 ns
- Configurable dither
- 12 inputs 5 V, configurable for AB and ABR incremental encoders
- 2x 5 V encoder supply with up to 200 mA
- Source connection of digital inputs for encoder's open collector outputs
- 1-wire connections

9.25.5.2 Order data

9.25.5.4 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

Status LED, left

| Figure | LED | Color | Status | Description |
|---|--------|-----------------------------|------------------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1 - 6 | Green | | Input state of the corresponding digital input |
| | l | Red | Off | Encoder supply lies in the valid range |
| On | | | Encoder supply is overloaded | |
| M1 + M2 | Orange | On | The corresponding output is active | |

- 1) Depending on the configuration, a firmware update can take up to several minutes.

Status LED, right

| Figure | LED | Color | Status | Description |
|---|---------|--------|--------|--|
|  | 7 - 12 | Green | | Input state of the corresponding digital input |
| | l | Red | Off | Encoder supply lies in the valid range |
| | | | On | Encoder supply is overloaded |
| | M3 + M4 | Orange | On | The corresponding output is active |

9.25.5.5 Connection elements

In accordance with the EN 60204-1 standard, a cable cross section of 1.5 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 10 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

The terminal block is not permitted to be plugged in or unplugged during operation.

Information:

Shielded motor cables must be used in order to meet the limits according to the EN 55011 standard (emissions).

9.25.5.5.1 X1 terminal block - DI 1 to 6 / PWM 1 and 2

9.25.5.5.2 X2 terminal block - DI 7 to 12 / PWM 3 and 4

9.25.5.5.3 X3 terminal block - Module supply

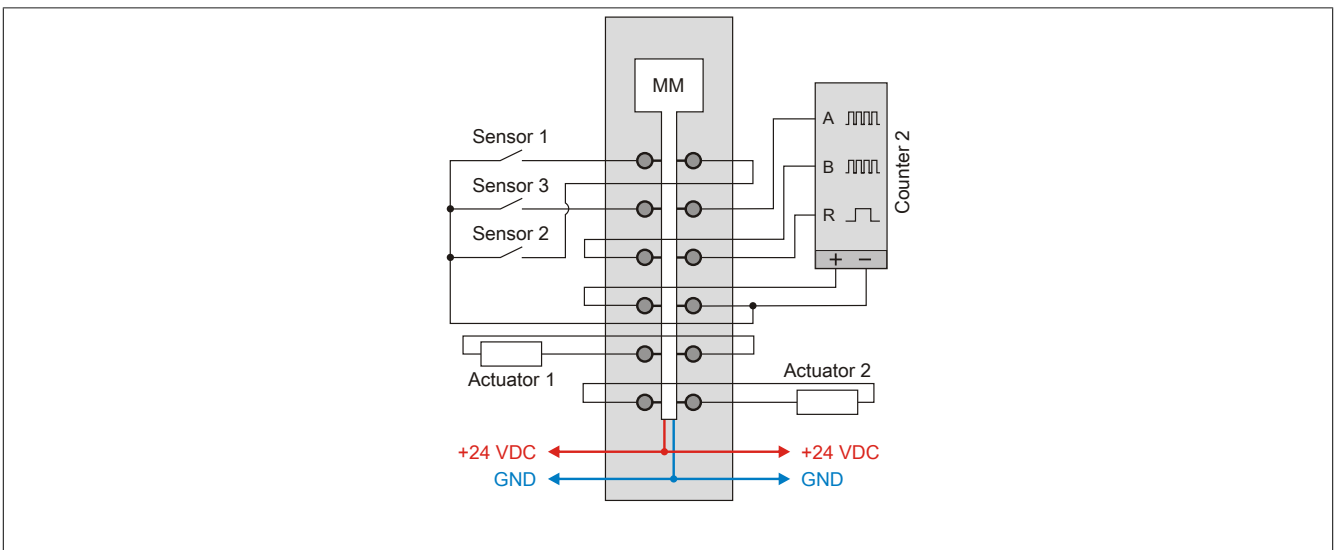

9.25.5.6 Connection examples

X1 and X2 terminal blocks

The following image shows a connection example for the X1 terminal block. The connection example also applies to the X2 terminal block.

Information:

In order to ensure proper function in all cases, the GND connection on the respective terminal block (X1 or X2) must always be used as reference ground for ABR encoders and digital inputs!

X3 terminal block

For information on the fuse being used, see "Protection" on page 2558.

9.25.5.7 Possible uses for digital inputs

Digital input channels 1 to 12 can be used as follows:

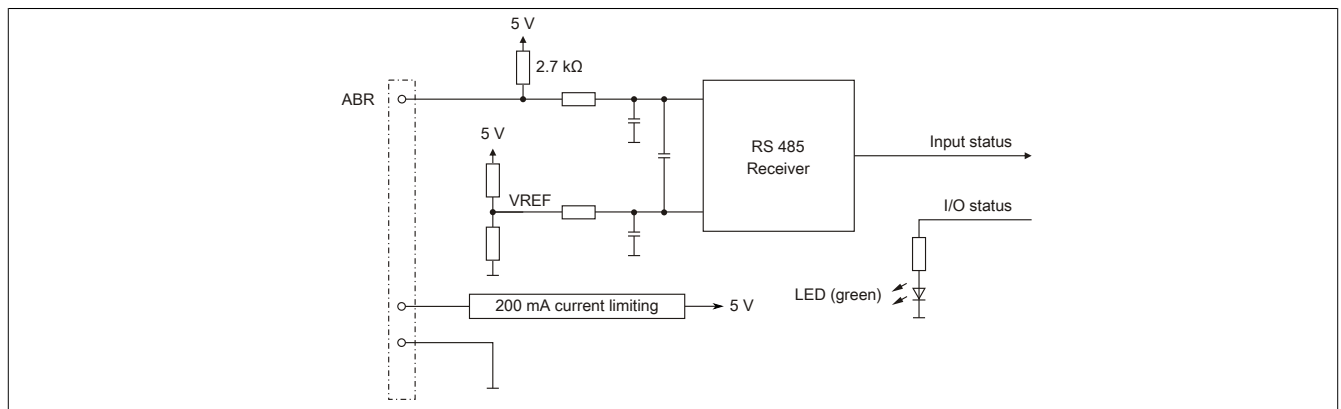

| Channel | Function | Special functions |
|---------|---------------|--|
| DI 1 | Digital input | A |
| DI 2 | Digital input | B |
| DI 3 | Digital input | Limit switch, trigger, reference pulse |
| DI 4 | Digital input | A |
| DI 5 | Digital input | B |
| DI 6 | Digital input | Limit switch, trigger, reference pulse |
| DI 7 | Digital input | A |
| DI 8 | Digital input | B |
| DI 9 | Digital input | Limit switch, trigger, reference pulse |
| DI 10 | Digital input | A |
| DI 11 | Digital input | B |
| DI 12 | Digital input | Limit switch, trigger, reference pulse |

The functions can also be mixed:

| Example 1 | |
|-----------|---------------|
| Channel | Function |
| DI 1 | Digital input |
| DI 2 | Digital input |
| DI 3 | Digital input |
| DI 4 | Digital input |
| DI 5 | Digital input |
| DI 6 | Digital input |
| DI 7 | A |
| DI 8 | B |
| DI 9 | R |
| DI 10 | A |
| DI 11 | B |
| DI 12 | R |

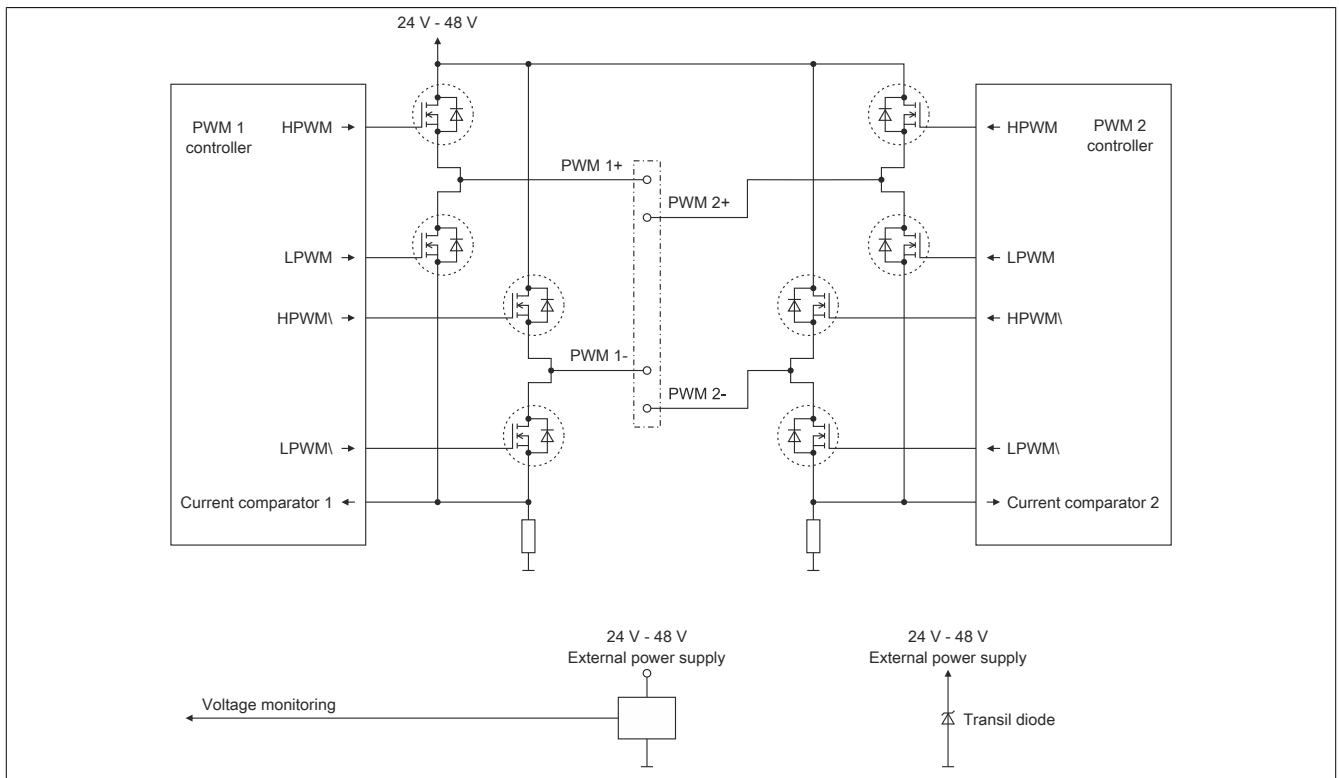

| Example 2 | |
|-----------|---------------|
| Channel | Function |
| DI 1 | A |
| DI 2 | B |
| DI 3 | R |
| DI 4 | Digital input |
| DI 5 | Digital input |
| DI 6 | Digital input |
| DI 7 | Digital input |
| DI 8 | Digital input |
| DI 9 | Digital input |
| DI 10 | A |
| DI 11 | B |
| DI 12 | R |

9.25.5.8 Input circuit diagram

9.25.5.9 Output circuit diagram

The following image shows the output circuit diagram for the outputs 1 and 2. The diagram also applies to the outputs 3 and 4.

9.25.5.10 Measurement of effective current

In current controller mode (see bit 12 in the ["configuration register" on page 2563](#)), there is an apparent deviation between the current setpoint and the measured effective current.

This is due to how the module operates. The PWM output remains "On" or in "Fast Decay" as long as needed to reach the current setpoint. Therefore, the current setpoint is the maximum or minimum current in a specified PWM cycle. This is why the effective current of this cycle (average current of this cycle) is lower (PWM = "On") or higher (PWM = "Fast Decay") than the current setpoint.

The size of the deviation depends on the load impedance.

9.25.5.11 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load, but is always less than the sum of the output currents. Make sure that the maximum nominal current of 31 A per pin is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the power mains and the rated current of the overcurrent protection used are chosen according to the current load so that the maximum current load for the cable cross section selected (based on the type of layout, see table) is greater than or equal to the current load in the power mains. The rated current of the overcurrent protection must be less than or equal to the maximum current load for the cable cross section selected (based on the type of layout, see table):

$$I_{\text{Mains}} \leq I_{\text{Fuse}} \leq I_{\text{Line/cable}}$$

| Wire cross section [mm ²] | Current load of the cable cross section I_z / rated current of the over current protection I_b [A] according to type of installation in an ambient air temperature of 40°C in accordance to EN 60204-1 | | | |
|---------------------------------------|--|-----------|-----------|-----------|
| | B1 | B2 | C | E |
| 1.5 | 13.5 / 13 | 13.1 / 10 | 15.2 / 13 | 16.1 / 16 |
| 2.5 | 18.3 / 16 | 16.5 / 16 | 21 / 20 | 22 / 20 |
| 4 | 24 / 24 | 23 / 20 | 28 / 25 | 30 / 25 |
| 6 | 32 / 32 | 29 / 25 | 36 / 32 | 37 / 32 |

Table 502: Cable cross section of the mains supply line depending on the type of layout

The tripping current of the fuse cannot exceed the rated current of fuse I_b .

| Type of layout | Description |
|----------------|------------------------------------|
| B1 | Wires in conduit or cable duct |
| B2 | Cables in conduit or cable duct |
| C | Cables or wires on walls |
| E | Cables or wires on open cable tray |

Table 503: Type of layout for the mains supply line

9.25.5.12 Monitoring the module supply

The module supply is continually monitored. If the following limits are exceeded in either direction, an error bit is set.

| | |
|----------------|-------|
| Upper limit: | >80 V |
| Warning stage: | >60 V |
| Lower limit: | <18 V |

9.25.5.13 Overvoltage cutoff

If the supply voltage on the module exceeds 80V (e.g. through feedback during generator operation), then all PWM outputs are disabled (PWM output pins are short-circuited). The outputs are reactivated as soon as the supply voltage is back in the valid range. Switching the outputs on again can cause an open load error in current mode (depending on the current setpoint and load inductance) as well as with any other abrupt change to the current setpoint value.

9.25.5.14 Overtemperature cutoff (at 85°C)

If the module temperature reaches or exceeds the limit value of 85°C, then the module executes the following actions:

- Setting the "overtemperature" error bit
- The PWM outputs are disabled (short-circuited)

Once the module temperature sinks to 83°C, the error bit is automatically cleared by the module and the outputs become operational again.

At an ambient temperature of 50°C and natural convection, the following overtemperature cutoff limits result with a uniform load on all 4 channels:

9.25.5.15 Derating

The temperature of the module is affected by the PWM period duration. The following derating must therefore be taken into account with a PWM period duration under 100 μs.

9.25.5.16 Let-through current I2T

The module is designed for let-through current of 360 A²s for a period of 10 seconds. If more current is needed for a certain time, less current must be drawn during the remaining time in order to maintain the let-through current.

Calculating the remaining-time current

$$I_{\text{Boost}}^2 \cdot t_{\text{Boost}} + I_{\text{Remaining}}^2 \cdot (10 - t_{\text{Boost}}) \leq 360 \text{ A}^2 \text{ s}$$

$$I_{\text{Remaining}} = \sqrt{\frac{360 \text{ A}^2 \text{ s} - I_{\text{Boost}}^2 \cdot t_{\text{Boost}}}{10 \text{ s} - t_{\text{Boost}}}}$$

Example

A boost current of 8 A is needed for a duration of 3 seconds.

$$I_{\text{Remaining}} = \sqrt{\frac{360 \text{ A}^2 \text{ s} - 8 \text{ A}^2 \cdot 3 \text{ s}}{10 \text{ s} - 3 \text{ s}}} = 4.89 \text{ A}$$

| t_{Boost} s | I_{Boost} A | $t_{\text{Remaining}}$ s | $I_{\text{Remaining}}$ A | I2T A ² · s |
|-------------------------|-------------------------|-----------------------------|-----------------------------|---------------------------|
| 10 | 6.00 | 0 | 0 | 360.00 |
| 2 | 10.00 | 8 | 4.47 | 360.00 |
| 3 | 8.57 | 7 | 4.47 | 360.00 |
| 4 | 7.75 | 6 | 4.47 | 360.00 |
| 5 | 7.21 | 5 | 4.47 | 360.00 |
| 6 | 6.83 | 4 | 4.47 | 360.00 |
| 7 | 6.55 | 3 | 4.47 | 360.00 |
| 8 | 6.32 | 2 | 4.47 | 360.00 |
| 9 | 6.15 | 1 | 4.47 | 360.00 |

These values correspond to the following curve for let-through current I2T:

9.25.5.17 Register description

9.25.5.17.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

1) The offset specifies the position of the register within the CAN object.

9.25.5.17.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "[Using I/O modules on the bus controller](#)" on page 3789.

9.25.5.17.3.2 CAN I/O bus controller

The module occupies 4 analog logical slots on CAN I/O.

9.25.5.17.4 Configuration

9.25.5.17.4.1 Configuration

Name:

Configuration01 to Configuration04

These registers can be used to configure the four DC motors.

The following placeholders are used in the configuration table:

| Register | Channel N | On |
|-----------------|-----------|------|
| Configuration01 | 1 | DI3 |
| Configuration02 | 2 | DI6 |
| Configuration03 | 3 | DI9 |
| Configuration04 | 4 | DI12 |

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|-----------|---|
| 0 - 1 | Configuration of the latch function for ABR counter N. The reference enable input is ignored. Enabling the latch function is described in register "Control" on page 2564 (bit 2): | 00 | ABR counter N is latched unconditionally (default setting). The reference enable input is ignored (bus controller default setting). |
| | | 01 | ABR counter N is latched if a rising edge occurs on digital input On. |
| | | 10 | ABR counter N is latched if a falling edge occurs on digital input On. |
| | | 11 | The latch function is disabled. |
| 2 | Reserved | 0 | |
| 3 | Active level of the reference enable input for ABR counter N: | 0 | Active level = High (bus controller default setting) |
| | | 1 | Active level = Low |
| 4 | Reserved | 0 | |
| 5 - 7 | Definition of the limit switch N (see also "Limit switch function"): | 000 | Limit switch N is disabled (bus controller default setting) |
| | | 001 | Digital input On is used as the Enable input. ¹⁾ |
| | | 010 | Digital input In is used as the limit switch |
| | | 011 - 111 | Reserved |
| 8 | Active level for limit switch N: | 0 | Active level = High (bus controller default setting) |
| | | 1 | Active level = Low |
| 9 - 10 | Trigger input for trigger counter "usSinceTrigger" N: | 00 | The trigger counter is disabled (bus controller default setting). |
| | | 01 | Digital input In is used as the trigger input |
| | | 10 - 11 | Reserved |
| 11 | Display of current average for output N: | 0 | If the corresponding setting has been enabled, then the average current value is indicated in register "CounterLatch[x]" on page 2570 (see bit 5 in the "control register" on page 2564) (bus controller default setting) |
| | | 1 | If the corresponding setting has been enabled, then the average current value is indicated in register "usSinceTrigger[x]" on page 2570 (see bit 5 in "Control" on page 2564). |
| 12 + 15 | Output mode N: | 00 | PWM mode (bus controller default setting) |
| | | 01 | Current mode |
| | | 10 | Boost-and-hold current control ¹⁾ |
| | | 11 | Reserved |
| 13 - 14 | Decay configuration for PWM N (see also "Decay configuration" on page 2573) | 00 | Slow decay (bus controller default setting) |
| | | 01 | Mixed decay |
| | | 10 - 11 | Reserved |

1) Only available with firmware version 1.3.0.0 or later

Limit switch function

The limit switch function serves to quickly shut off the PWM outputs when a limit position is reached.

The limit switch is activated and the disable edge (rising or falling) on the limit switch input is selected using bits 6 to 8.

A PWM output is deactivated as soon as the configured disable edge is reached on the corresponding input of the limit switch. It remains deactivated until either the limit switch function is deactivated or the limit switch is acknowledged with bit 4 in the respective "control register" on page 2564.

Enable input

The limit switch input of the module can optionally be used as an enable input. Bits 5 to 7 must be configured accordingly for this. Data point [OutputEnable](#) and the digital input are logically linked by an AND operator.

When the enable input is enabled, the PWM output can be switched on and off via the digital input. Switching on and off is done with a jitter of 50 µs. Since it is possible to react only at the beginning of the PWM period, an additional jitter of the length of the [PWM period duration](#) must be taken into account.

9.25.5.17.4.2 Control

Name:

TriggerEdge01 to TriggerEdge04

StartTrigger01 to StartTrigger04

StartLatch01 to StartLatch04

DitherDisable01 to DitherDisable04

ClearError01 to ClearError04

ShowMeanCurrent01 to ShowMeanCurrent04

ResetCounter01 to ResetCounter04

OutputEnable01 to OutputEnable04

These registers can be used to configure the behavior of the trigger, the ABR counter and the dither.

[N] stands for the corresponding control number.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|--|-------|--|
| 0 | TriggerEdgeN Configuration of trigger edge for "usSinceTrigger": | 0 | Counting starts at rising edge |
| | | 1 | Counting starts at falling edge |
| 1 | StartTriggerN Enabling of "usSinceTrigger" due to a status change of bit 1 | x | Counting starts at the next trigger edge (see bit 0). For more information about trigger functionality, see " Trigger function procedure " on page 2564. |
| | | | |
| 2 | StartLatchN Latching or referencing ABR counters: | 0 | Disabled |
| | | 1 | Enabled |
| 3 | DitherDisable N | 0 | Dither for PWM output N is enabled (default setting). The dither frequency and dither amplitude must be greater than 0 (see " Dither " on page 2568). |
| | | 1 | Dither for PWM output N is disabled. |
| 4 | ClearErrorN Acknowledging error or limit switch: | 0 | No effect |
| | | 1 | Error acknowledgment on output N (overcurrent or open load) or acknowledgment of limit switch N |
| 5 | ShowMeanCurrentN Configuration of registers CounterLatch and usSinceTrigger | 0 | Register CounterLatch N contains the latched counter value. Register usSinceTriggerN contains the trigger counter. |
| | | 1 | Both registers contain the current PWM output current |
| 6 | ResetCounterN Reset ABR counter | 0 | Enable ABR counter |
| | | 1 | Reset ABR counter |
| 7 | OutputEnableN ¹⁾ | 0 | Switch off the PWM output |
| | | 1 | Switch on the PWM output |

1) Only for boost-and-hold current control

Trigger function procedure

The following points must be taken into consideration when configuring or activating the trigger function:

- Select the desired trigger edge using bit 0
- Enable the trigger function by changing the state of StartTrigger (bit 1). This edge clears the register [usSinceTrigger](#) (µs counter).
- When the trigger event occurs, the µs counter [usSinceTrigger](#) is started.
- The counter [usSinceTrigger](#) cannot overrun, i.e. the counter is stopped at $2^{16}-1$ and retains this value until the next time the trigger function is activated.
- The trigger function can be re-activated at any time by changing the state of StartTrigger (bit 1) regardless of if a trigger event has occurred or if "usSinceTrigger" has reached its maximum value.

Reset ABR counter

Bit 6 sets the following counters and status bits to 0:

- ABR counter
- Latch value of the ABR counter
- Latching started on the ABR counter (bit 4 of the "status register" on page 2571)
- ABR counter successfully latched (bit 5 of the "status register" on page 2571)

Please note that a started latch procedure is no longer active after the ABR counter has been reset. This means that latching must be restarted by a rising edge on bit 2.

OutputEnable

Bit 7 can start or stop the output profile in [Boost-and-hold current control](#). If a rising edge occurs on this data point, any pending [Overcurrent error](#) or [Open load error](#) of the associated PWM output are acknowledged and the output is switched on.

Starting or stopping occurs immediately after the transfer of the value on the X2X Link network with a jitter of 50 μ s. Note that during startup, an additional jitter of the length of the [PWM period duration](#) of the current controller is added.

Starting and stopping the output profile can also be controlled by the digital input. See ["Enable input" on page 2564](#).

9.25.5.17.4.3 Difference between operating modes

The module provides the following operating modes:

- [PWM mode](#)
- [Current mode](#)
- [Boost-and-hold current control](#)

The following images illustrate how the current curves for the outputs are affected by registers ["PWM period duration" on page 2566](#) and ["PWM pulse width" on page 2567](#).

PWM mode

At the beginning of each period, the output is switched on for the percentage of time set in the PWM pulse width.

Current mode

At the beginning of each period, the current output is switched on. After reaching the value set in ["PulseWidthCurrentPWM" on page 2567](#), the output is switched off and the voltage drops according to the set [decay configuration](#) until it is next switched on.

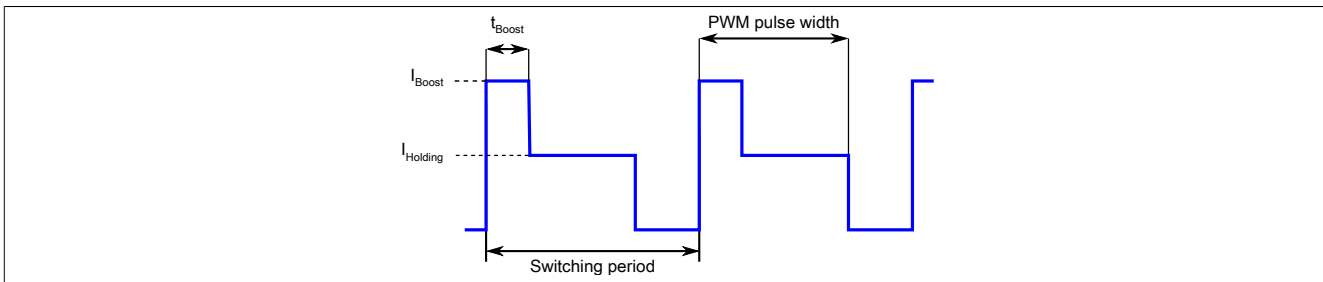

Boost-and-hold current control**Information:**

Only available with firmware version 1.3.0.0 or later.

In this operating mode, the current mode is combined with a higher-level PWM mode.

After the time (t_{Boost}) set in register "BoostTime" on page 2567, the inrush current (I_{Boost}) is changed to the holding current (I_{Holding}) specified in register "HoldingCurrent" on page 2568.

The period duration of the current profile is set in register "SwitchingPeriod" on page 2568 in 50- μs steps. In addition, the PWM period duration must be set in register PeriodDurationPWM. (Not shown, see Current mode.)

**Example: Controlling a digital valve**

The boost current (I_{Boost}) is used to quickly open a digital valve, for example. After the boost time (t_{Boost}), the current is reduced to the lower holding current (I_{Holding}) in order to save energy and not overload the PWM output. I_{Holding} is therefore set to a smaller value than I_{Boost} .

The pulse width can be used to set the opening time of the valve in relation to the period duration. After the period duration has expired, I_{Boost} is started again. If the valve should remain open continuously, the pulse width must be set to 100%. In this case, no boost current is output at the beginning of the next period.

I_{Boost} is only output if the valve has been switched off for at least 50 μs . If the pulse width is set smaller than t_{Boost} , the boost time is shortened accordingly.

9.25.5.17.4.4 PWM period duration

Name:

PeriodDurationPWM

This register can be used to set the period duration between 20 μs (50 kHz) and 65535 μs (15 Hz). See also "Difference between operating modes" on page 2565.

| Data type | Value | Information |
|-----------|-------------|-----------------------|
| UINT | 20 to 65535 | Time in μs |

9.25.5.17.4.5 PWM pulse width

Name:

PulseWidthCurrentPWM01 to PulseWidthCurrentPWM04

The PWM pulse width (PWM mode) or current setting (in current mode) is entered in this register according to the setting in the module configuration register. (see also ["Difference between operating modes"](#) on page 2565.) A negative value changes the output polarity.

PWM mode

| Data type | Value | Output + | Output - |
|-----------|--------|--------------------------------------|--------------------------------------|
| INT | 32767 | High | Low |
| | 16384 | PWM 50/50 | Low |
| | 0 | Low (bus controller default setting) | Low (bus controller default setting) |
| | -16384 | Low | PWM 50/50 |
| | -32767 | Low | High |

Current mode

| Data type | Value | Current mode |
|-----------|------------------|------------------------|
| INT | 19661 to 32767 | 6 to 10 A (max. 2 s) |
| | 19660 | 6 A |
| | 0 | 0 A |
| | -19660 | -6 A |
| | -19661 to -32767 | -6 to -10 A (max. 2 s) |

| Data type | Values | Information |
|-----------|-----------------|-------------------|
| INT | -32768 to 32767 | For -100% to 100% |

Resolution/Derating

As mentioned earlier in the technical data, the PWM resolution is 15-bit (+ sign). This value is derated for a period duration of less than 328 μs because of the minimal PWM timing resolution (10 ns) (see following diagram). With the minimum PWM period duration of 20 μs , the PWM has 11-bit resolution (+ sign):

9.25.5.17.4.6 Boost-and-hold registers

Boost current

Name:

BoostCurrent01 to BoostCurrent04

The boost current is set in mA in this register.

| Data type | Values | Information |
|-----------|------------|---------------|
| INT | 0 to 10000 | For 0 to 10 A |

Boost time

Name:

BoostTime01 to BoostTime04

The sampling time is set in μs in this register. The entered value is rounded up to the next largest 50- μs interval.

| Data type | Values | Information |
|-----------|------------|------------------|
| UINT | 0 to 65500 | In μs |

Holding current

Name:

HoldingCurrent01 to HoldingCurrent04

The holding current is set in mA in this register. After the boost time, the current for the remaining pulse width time is raised or lowered to this value.

| Data type | Values | Information |
|-----------|-----------|--------------|
| UINT | 0 to 6000 | For 0 to 6 A |

Period duration of the current profile

Name:

SwitchingPeriod01 to SwitchingPeriod04

This register is used to set the period duration of the current profile in μs for boost-and-hold mode. The entered value is rounded up to the next largest 50- μs interval.

| Data type | Values | Information |
|-----------|---------------|--------------------------------|
| UINT | 2000 to 65500 | Corresponds to 500 to 15.26 Hz |

Synchronous operation of channels

In order for 2 or more channels to run synchronously, their period durations of the output profile ([SwitchingPeriod](#)) must be set to the same value or to a multiple of the other channel. An exact phase position of 0 degrees can only be guaranteed if the channels are switched on simultaneously (in the same bus cycle) with [OutputEnable](#).

To operate the current profile synchronously to the X2X Link network, [SwitchingPeriod](#) should be set to a multiple of the bus cycle.

9.25.5.17.4.7 Dither

When the position setpoint for valves remains constant for a long period of time, especially in fluids, there is a risk that a valve will stick. This is normally prevented using "dithering". When doing so, the value is permitted to slightly oscillate around the position setpoint.

By default, the dither is active for both outputs as soon as the [dither amplitude](#) and [dither frequency](#) are set to a value >0 . If necessary, the dither can be disabled for each output individually or simultaneously (see bit 3 in register "[control register](#)" on [page 2564](#)).

No dither is used in boost-and-hold mode of the PWM output. Any set dither amplitude and dither frequency are ignored by the module.

Dither amplitude

Name:

ConfigOutput01

This register can be used to configure the amplitude value or pulse width.

| Data type | Value | Information |
|-----------|----------|---|
| USINT | 0 to 255 | Current mode: 0 to 25.5% of the module's nominal current ¹⁾ PWM mode: 0 to 25.5% of the period duration. Bus controller default setting: 0 |

1) See the technical data for the module.

Dither frequency

Name:

ConfigOutput02

This register can be used to set the frequency in 2 Hz steps.

| Data type | Value | Information |
|-----------|----------|--|
| USINT | 0 to 255 | Corresponds to 0 to 510 Hz. Bus controller default setting: 0 |

Dither example

The values specified in the data sheet for a valve should be used to calculate [Dither amplitude](#) and [Dither frequency](#).

Data sheet for the valve

The data sheet for a valve manufacturer recommends the following dithering:

Dither height in percent (A_{Dither}): 20 to 35% (peak values) of the nominal valve current of 2 A

Dither frequency in Hertz (F_{Dither}): 40 to 70 Hz

Selected values

These values correspond to the average values on the valve data sheet.

$A_{\text{Dither}} = 27\%$ of the valve's nominal current (peak values)

$F_{\text{Dither}} = 56 \text{ Hz}$

Formulas

[Dither amplitude](#) = $(A_{\text{Dither}} / 2) * (\text{Nominal current}_{\text{Valve}} / \text{Nominal current}_{\text{Module}}) * 10$

Info: $(A_{\text{Dither}} / 2)$ = Conversion of the peak values to amplitude, " * 10" = Scaling of the dither amplitude to 1/10%

[Dither frequency](#) = $F_{\text{Dither}} / 2 \text{ Hz}$

Info: Dither frequency is configured in 2 Hz steps.

Calculation

By using the selected values in the formulas.

[Dither amplitude](#) = $27\% / 2 * (2 \text{ A} / 6 \text{ A}) * 10 = 45$

[Dither frequency](#) = $56 \text{ Hz} / 2 \text{ Hz} = 28$

9.25.5.17.5 Communication

9.25.5.17.5.1 ABR counter

Name:

Counter01 to Counter04

These registers are 16-bit AB(R) counters.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.5.17.5.2 ABR counter latch

Name:

CounterLatch01 to CounterLatch04

When a latch event occurs, the current counter values are saved in these registers. For additional features, see bit 5 in the respective ["control register" on page 2564](#).

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.5.17.5.3 Microseconds since trigger

Name:

usSinceTrigger01 to usSinceTrigger04

This register shows either the time in μs since the last trigger event or the average current value.

- The usSinceTrigger counter cannot overrun, i.e. the counter is stopped at $2^{16}-1$ and retains this value until the next time the trigger function is activated.
- If the average current is displayed in this register (bit 11 in the respective ["configuration register" on page 2563](#)), then the data type of usSinceTrigger in Automation Studio must be unsigned integer (UINT). The average current value, on the other hand, is an Integer (INT). This means that negative currents are displayed between 32,769 and 65,535.

Counting mode

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Measurement of average current value

| Data type | Value | Information |
|-----------|------------------|---------------------------------------|
| INT | 19,661 to 32,767 | 6 to 10 A |
| | 19,660 | 6 A |
| | 1 | 305 μA (= 10 A / 32,767) |
| | 0 | 0 A |
| | 65,535 | -305 μA (= -10 A / 32,767) |
| | 45,876 | -6 A |
| | 45,875 to 32,769 | -6 to -10 A |

9.25.5.17.5.4 Status of the inputs

Name:

StatusInput01 to StatusInput12

EncoderPowerSupplyError01 to EncoderPowerSupplyError02

nLatchPending01 to nLatchPending04

LatchDone01 to LatchDone04

EndswitchReached01 to EndswitchReached04

PWMError01 to PWMError0

These registers indicate the status of the inputs and outputs for each DC motor.

The following placeholders are used in the status table.

| Register | [x] | In1 | In2 | In3 | Enc |
|--------------------|-----|------|------|------|-----|
| Status of inputs 1 | 1 | DI1 | DI2 | DI3 | 01 |
| Status of inputs 2 | 2 | DI4 | DI5 | DI6 | - |
| Status of inputs 3 | 3 | DI7 | DI8 | DI9 | 02 |
| Status of inputs 4 | 4 | DI10 | DI11 | DI12 | - |

| Data type | Value |
|---------------------|--------------------|
| USINT ¹⁾ | See bit structure. |
| UINT ²⁾ | See bit structure. |

1) Function model 0 and function model 254 → registers "Status of inputs 3" and "Status of inputs 4"

2) Only function model 254 → registers "Status of inputs 1" and "Status of inputs 2"

Bit structure:

| Bit | Description | Value | Information |
|--------|------------------------------------|-------|---|
| 0 | StatusInput [In1] | x | Ein1 is used for the encoder signal A of ABR counter [x]. |
| 1 | StatusInput [In2] | x | Ein2 is used for the encoder signal B of ABR counter [x]. |
| 2 | StatusInput [In3] | 0 | Possible uses for the digital input <ul style="list-style-type: none"> • Trigger input [x] • Limit switch [x] • Referencing of the ABR counter [x] |
| 3 | EncoderPowerSupplyErrorInput [Enc] | 0 | Error free operation |
| | | 1 | Encoder power supply error |
| 4 | nLatchPending [x] | 00 | Latching started |
| | | 01 | ABR counter latch [x] ready. Latch not yet started. |
| 5 | LatchDone [x] | 0 | The status of this bit is changed each time ABR counter [x] is successfully latched |
| 6 | EndswitchReached [x] | 00 | No effect on PWM output [x] |
| | | 01 | Limit switch [x] reached. PWM output [x] disabled. |
| 7 | PWMError [x] | 0 | Error free operation |
| | | 1 | An error has occurred. The error can be determined by evaluating the two error registers "Global errors" on page 2573 and "Channel errors" on page 2572. |
| 8 - 15 | Only function model 254 | | |
| | Status of inputs 1 | x | With "Status of inputs 1", bits 12 to 15 contain error bits 4 to 7 from the register "Global error" on page 2573 |
| | Status of inputs 2 | x | With "Status of inputs 2", bits 8 to 15 contain error bits 0 to 7 from the register "Channel errors" on page 2572 |

9.25.5.17.5.5 Channel errors

Name:

CurrentError01 to CurrentError04

OverCurrentError01 to OverCurrentError04

If an error is detected, the corresponding error bit in this register remains set until the error is acknowledged using bit 4 in the respective "control register" on page 2564.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|--------------------|-------|--|
| 0 | CurrentError01 | 0 | No error |
| | | 1 | Open load error |
| 1 | OverCurrentError01 | 0 | No error |
| | | 1 | Overcurrent error, output deactivated. |
| 2 | CurrentError02 | 0 | No error |
| | | 1 | Open load error |
| 3 | OverCurrentError02 | 0 | No error |
| | | 1 | Overcurrent error, output deactivated. |
| 4 | CurrentError03 | 0 | No error |
| | | 1 | Open load error |
| 5 | OverCurrentError03 | 0 | No error |
| | | 1 | Overcurrent error, output deactivated. |
| 6 | CurrentError04 | 0 | No error |
| | | 1 | Open load error |
| 7 | OverCurrentError04 | 0 | No error |
| | | 1 | Overcurrent error, output deactivated. |

Overcurrent error

An overcurrent error is registered if one of the following conditions is met:

- ≥ 10 A flow from a PWM output for at least 2 seconds
- ≥ 16 A flow for 3 consecutive PWM cycles
- All PWM outputs together consume more than 32 A on the X3 connector

In all three cases, the affected PWM output is deactivated by the firmware (i.e. the pins on the PWM output are short-circuited). The user must acknowledge the error using bit 4 in the respective "control register" on page 2564 before a PWM output deactivated in this manner can be made operational again.

Open load error

An open load error is only registered in current control mode (see bit 12 in the respective "configuration register" on page 2563) if the current setpoint is not reached. In some cases this can be caused by an open line, although usually the impedance of the load is too high.

9.25.5.17.5.6 Global error

Name:

OverVoltageError

UnderVoltageError

VoltageWarning

OvertemperatureError

This register indicates overtemperature and errors in the module supply. The error bits are automatically acknowledged by the module as soon as the values are back within the permissible limits.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------------|-------|--|
| 0 - 3 | Reserved | 0 | |
| 4 | OverVoltageError | 0 | No error |
| | | 1 | Voltage >80 V. All outputs are deactivated. |
| 5 | UnderVoltageError | 0 | No error |
| | | 1 | Voltage <18 V |
| 6 | VoltageWarning | 0 | No error |
| | | 1 | Voltage >60 V |
| 7 | OvertemperatureError | 0 | No error |
| | | 1 | Module overtemperature; all outputs are deactivated. |

9.25.5.17.5.7 Temperature

Name:

ModuleTemperature

The module temperature is displayed in this register.

| Data type | Value | Information |
|-----------|------------|--------------------------|
| SINT | -40 to 125 | Module temperature in °C |

9.25.5.17.6 Decay configuration

The decay configuration determines the method and dynamics of current reduction for inductive loads or motors.

"Slow decay" is configured by default. In this mode, the current is automatically reduced relatively slowly with resistance in the load. No energy is regenerated into the module.

"Mixed decay" mode is recommended for applications that require a dynamic and linear reduction of current. In this mode, energy is regenerated into the module during part of the PWM cycle (fast decay).

9.25.5.17.6.1 Current control

As its name suggests, mixed decay mode is a mix of "slow decay" and "fast decay". This occurs as follows:

A check is made at the beginning of each PWM cycle to determine if the actual current for the phases is below the set current. If this is the case, PWM is enabled (On) until the current setpoint is reached. If the current setpoint has already been exceeded at the beginning of the PWM cycle (generator operation), the system immediately switches to fast decay mode until the current setpoint is exceeded. The rest of the PWM cycle always takes place in slow decay mode.

This also permits generator operation as long as the valid range for the supply voltage has not been exceeded due to the regeneration into the DC circuit.

Current control in Mixed Decay mode

Current control in Slow Decay mode

9.25.5.17.6.2 PWM control

When Mixed Decay mode is enabled, the outputs are driven in Fast Decay mode up until 50% of the period and in Slow Decay mode for the remainder of the switch-off phase.

When Slow Decay mode is used, it is immediately enabled during the switch-off phase.

PWM control in Mixed Decay mode (pulse duty factor = 37.5%)

PWM control in Slow Decay mode (pulse duty factor = 37.5%)

Operating DC motors

In PWM mode, the motor current is limited to the maximum current (10 A), independent of the supply voltage.

However, the motor switches to generator operation when braking. Because of the counter EMF, which is dependent on the rotary speed, a current is generated in the module that is only limited by the internal resistance of the motor. This is not permitted to exceed 15 A (maximum 2 seconds).

The counter EMF closely corresponds to the voltage needed to achieve this speed. Therefore, the maximum brake current is very easy to calculate with the following formula.

$$I_{Brake} = U_e * \frac{PulseWidth}{100\%} * \frac{1}{R_{Motor}}$$

Example:

| | |
|------------------------------|----------------------|
| Module supply | 42 V |
| Pulse width | 16364 (equal to 50%) |
| Internal resistance of motor | 3.5 Ω |

$$I_{Brake} = 38 \text{ V} * \frac{50}{100\%} * \frac{1}{3.5\Omega} = 5.4A$$

9.25.5.17.7 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| |
|---------------------------|
| Minimum cycle time |
| 400 μs |

9.25.5.17.8 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| |
|--------------------------------|
| Minimum I/O update time |
| 400 μs |

9.25.6 X20MM4456

Data sheet version: 2.21

9.25.6.1 General information

The PWM motor bridge module is used to control 4 DC motors with a nominal voltage of 24 to 48 VDC $\pm 25\%$ at a nominal current up to 6 A. The module can be reconfigured and used in current controller mode for controlling inductive loads. The module is also equipped with 16 digital inputs, which can be used as incremental counters. The 4 motors are controlled with a full-bridge (H-bridge). This enables the motors to be moved in both directions.

- 4x outputs (H bridge) with PWM control and 24 to 48 VDC $\pm 25\%$ supply
- 6 A nominal current (10 A max current)
- 15 Hz to 50 kHz frequency, 16-bit
- PWM resolution, 15-bit, + sign, minimum 10 ns
- Configurable dither
- 4x 4 inputs 24V, can be configured as ABR
- Sink connection
- 1-wire connections

9.25.6.4 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

Status LED, left

| Figure | LED | Color | Status | Description |
|---|---------|-----------------------------|--------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | e | Red | On | RUN mode |
| | | | Off | No power to module or everything OK |
| | e + r | Red on / Green single flash | On | Error or reset status |
| | | | Off | Invalid firmware |
| | 1 - 8 | Green | | Input state of the corresponding digital input |
| | M1 + M2 | Orange | On | The corresponding output is active |

1) Depending on the configuration, a firmware update can take up to several minutes.

Status LED, right

| Figure | LED | Color | Status | Description |
|---|---------|--------|--------|--|
|  | 9 - 16 | Green | | Input state of the corresponding digital input |
| | M3 + M4 | Orange | On | The corresponding output is active |
| | | | | |

9.25.6.5 Connection elements

In accordance with the EN 60204-1 standard, a cable cross section of 1.5 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 10 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

The terminal block is not permitted to be plugged in or unplugged during operation.

Information:

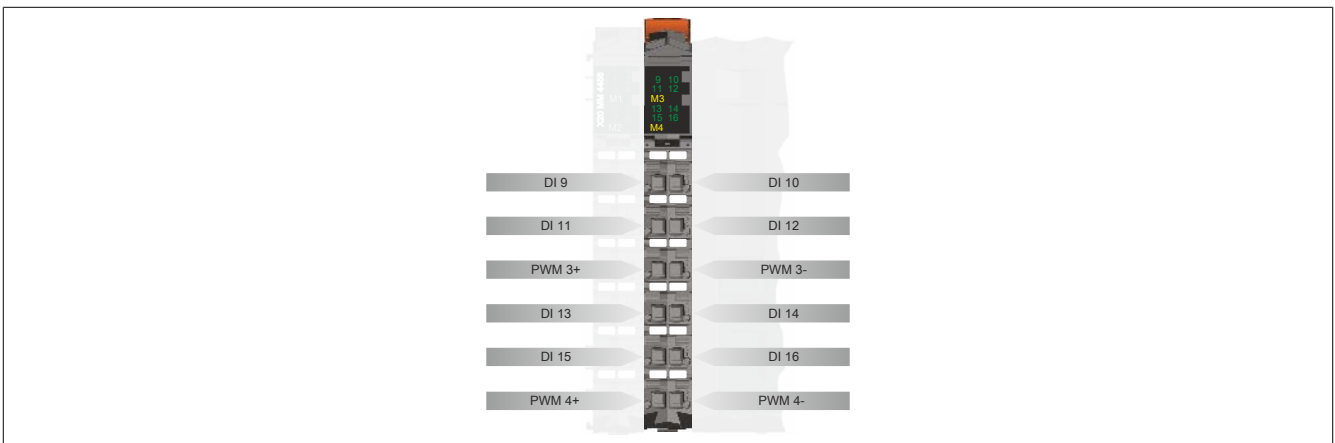

Shielded motor cables must be used in order to meet the limits according to the EN 55011 standard (emissions).

9.25.6.5.1 Terminal block X1 - DI 1 - 8 / PWM 1 + 2

9.25.6.5.2 Terminal block X2 - DI 9 - 16 / PWM 3 + 4

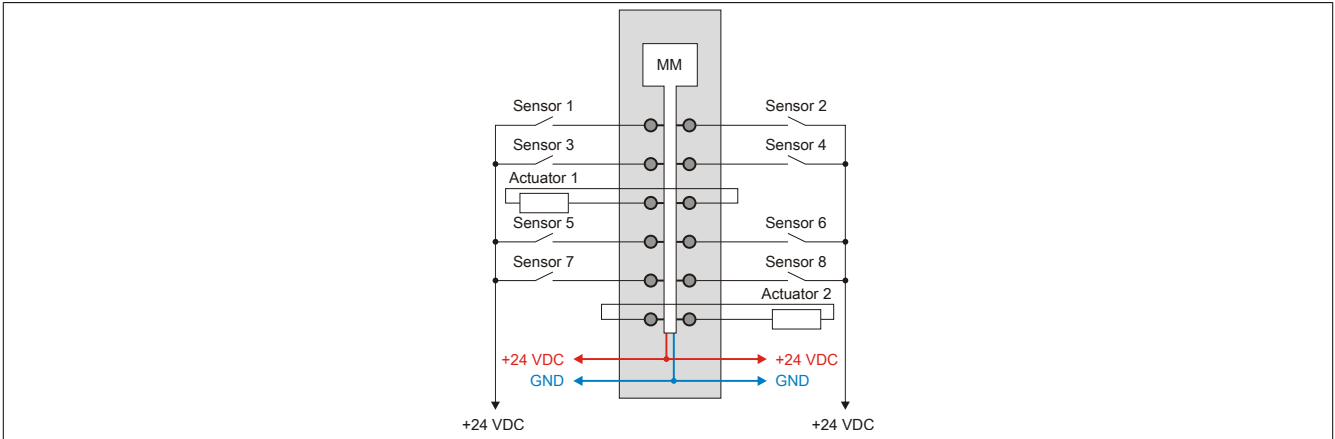

9.25.6.5.3 X3 terminal block - Module supply

9.25.6.6 Connection examples

X1 and X2 terminal blocks

The following image shows a connection example for the X1 terminal block. The connection example also applies to the X2 terminal block.

X3 terminal block

For information on the fuse used, see "Protection" on page 2583.

9.25.6.7 Possible uses for digital inputs

Digital input channels 1 to 16 can be used as follows:

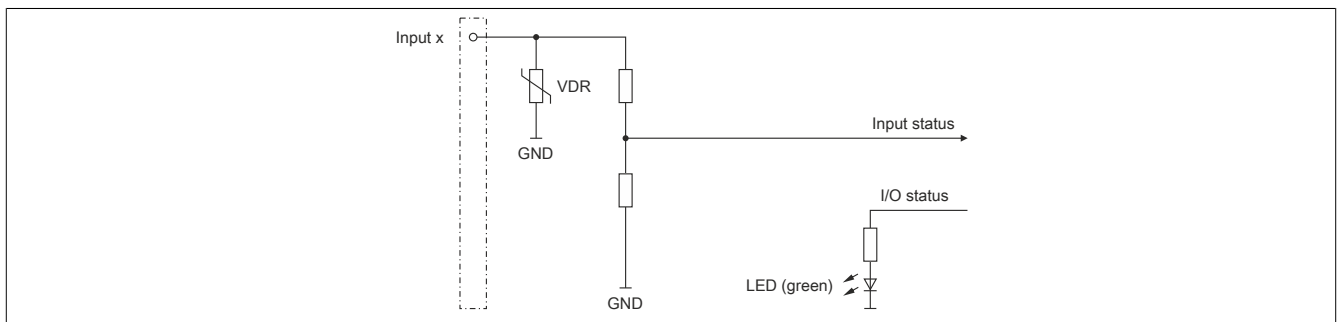

| Channel | Function | Special functions |
|---------|---------------|---|
| DI 1 | Digital input | A |
| DI 2 | Digital input | B |
| DI 3 | Digital input | Limit switch, trigger, reference pulse |
| DI 4 | Digital input | Limit switch, trigger, reference enable |
| DI 5 | Digital input | A |
| DI 6 | Digital input | B |
| DI 7 | Digital input | Limit switch, trigger, reference pulse |
| DI 8 | Digital input | Limit switch, trigger, reference enable |
| DI 9 | Digital input | A |
| DI 10 | Digital input | B |
| DI 11 | Digital input | Limit switch, trigger, reference pulse |
| DI 12 | Digital input | Limit switch, trigger, reference enable |
| DI 13 | Digital input | A |
| DI 14 | Digital input | B |
| DI 15 | Digital input | Limit switch, trigger, reference pulse |
| DI 16 | Digital input | Limit switch, trigger, reference enable |

The functions can also be mixed:

| Example 1 | |
|-----------|---------------|
| Channel | Function |
| DI 1 | Digital input |
| DI 2 | Digital input |
| DI 3 | Digital input |
| DI 4 | Digital input |
| DI 5 | Digital input |
| DI 6 | Digital input |
| DI 7 | Digital input |
| DI 8 | Digital input |
| DI 9 | A |
| DI 10 | B |
| DI 11 | R |
| DI 12 | |
| DI 13 | A |
| DI 14 | B |
| DI 15 | R |
| DI 16 | |

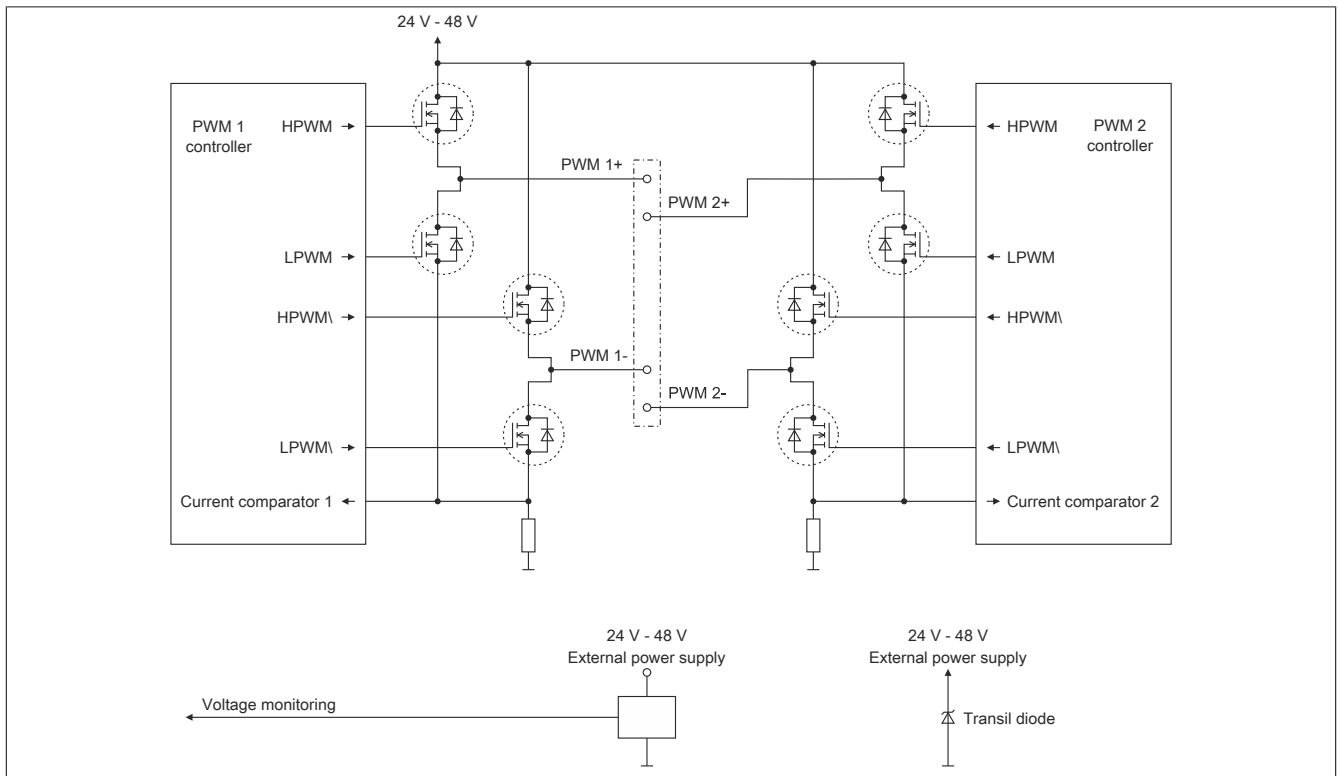

| Example 2 | |
|-----------|---------------|
| Channel | Function |
| DI 1 | A |
| DI 2 | B |
| DI 3 | R |
| DI 4 | |
| DI 5 | Digital input |
| DI 6 | Digital input |
| DI 7 | Digital input |

| DI 8 | Digital input |
| DI 10 | Digital input |
| DI 11 | Digital input |
| DI 12 | Digital input |
| DI 13 | A |
| DI 14 | B |
| DI 15 | R |
| DI 16 | |

9.25.6.8 Input circuit diagram

9.25.6.9 Output circuit diagram

The following image shows the output circuit diagram for the outputs 1 and 2. The diagram also applies to the outputs 3 and 4.

9.25.6.10 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load, but is always less than the sum of the output currents. Make sure that the maximum nominal current of 31 A per pin is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the power mains and the rated current of the overcurrent protection used are chosen according to the current load so that the maximum current load for the cable cross section selected (based on the type of layout, see table) is greater than or equal to the current load in the power mains. The rated current of the overcurrent protection must be less than or equal to the maximum current load for the cable cross section selected (based on the type of layout, see table):

$$I_{\text{Mains}} \leq I_{\text{Fuse}} \leq I_{\text{Line/cable}}$$

| Wire cross section [mm ²] | Current load of the cable cross section I_z / rated current of the over current protection I_b [A] according to type of installation in an ambient air temperature of 40°C in accordance to EN 60204-1 | | | |
|---------------------------------------|--|-----------|-----------|-----------|
| | B1 | B2 | C | E |
| 1.5 | 13.5 / 13 | 13.1 / 10 | 15.2 / 13 | 16.1 / 16 |
| 2.5 | 18.3 / 16 | 16.5 / 16 | 21 / 20 | 22 / 20 |
| 4 | 24 / 24 | 23 / 20 | 28 / 25 | 30 / 25 |
| 6 | 32 / 32 | 29 / 25 | 36 / 32 | 37 / 32 |

Table 506: Cable cross section of the mains supply line depending on the type of layout

The tripping current of the fuse cannot exceed the rated current of fuse I_b .

| Type of layout | Description |
|----------------|------------------------------------|
| B1 | Wires in conduit or cable duct |
| B2 | Cables in conduit or cable duct |
| C | Cables or wires on walls |
| E | Cables or wires on open cable tray |

Table 507: Type of layout for the mains supply line

9.25.6.11 Monitoring the module supply

The module supply is continually monitored. If the following limits are exceeded in either direction, an error bit is set.

| | |
|----------------|-------|
| Upper limit: | >80 V |
| Warning stage: | >60 V |
| Lower limit: | <18 V |

9.25.6.12 Overvoltage cutoff

If the supply voltage on the module exceeds 80V (e.g. through feedback during generator operation), then all PWM outputs are disabled (PWM output pins are short-circuited). The outputs are reactivated as soon as the supply voltage is back in the valid range. Switching the outputs on again can cause an open load error in current mode (depending on the current setpoint and load inductance) as well as with any other abrupt change to the current setpoint value.

9.25.6.13 Overtemperature cutoff (at 85°C)

If the module temperature reaches or exceeds the limit value of 85°C, then the module executes the following actions:

- Setting the "overtemperature" error bit
- The PWM outputs are disabled (short-circuited)

Once the module temperature sinks to 83°C, the error bit is automatically cleared by the module and the outputs become operational again.

9.25.6.14 Measurement of effective current

In current controller mode (see bit 12 in the "configuration register" on page 2588), there is an apparent deviation between the current setpoint and the measured effective current.

This is due to how the module operates. The PWM output remains "On" or in "Fast Decay" as long as needed to reach the current setpoint. Therefore, the current setpoint is the maximum or minimum current in a specified PWM cycle. This is why the effective current of this cycle (average current of this cycle) is lower (PWM = "On") or higher (PWM = "Fast Decay") than the current setpoint.

The size of the deviation depends on the load impedance.

9.25.6.15 Derating

The temperature of the module is affected by the PWM period duration. The following derating must therefore be taken into account with a PWM period duration under 100 μ s.

9.25.6.16 Let-through current I2T

The module is designed for let-through current of 360 A²s for a period of 10 seconds. If more current is needed for a certain time, less current must be drawn during the remaining time in order to maintain the let-through current.

Calculating the remaining-time current

$$I_{\text{Boost}}^2 \cdot t_{\text{Boost}} + I_{\text{Remaining}}^2 \cdot (10 - t_{\text{Boost}}) \leq 360 \text{ A}^2 \text{ s}$$

$$I_{\text{Remaining}} = \sqrt{\frac{360 \text{ A}^2 \text{ s} - I_{\text{Boost}}^2 \cdot t_{\text{Boost}}}{10 \text{ s} - t_{\text{Boost}}}}$$

Example

A boost current of 8 A is needed for a duration of 3 seconds.

$$I_{\text{Remaining}} = \sqrt{\frac{360 \text{ A}^2 \text{ s} - 8 \text{ A}^2 \cdot 3 \text{ s}}{10 \text{ s} - 3 \text{ s}}} = 4.89 \text{ A}$$

| t_{Boost} s | I_{Boost} A | $t_{\text{Remaining}}$ s | $I_{\text{Remaining}}$ A | I2T A ² · s |
|-------------------------|-------------------------|-----------------------------|-----------------------------|---------------------------|
| 10 | 6.00 | 0 | 0 | 360.00 |
| 2 | 10.00 | 8 | 4.47 | 360.00 |
| 3 | 8.57 | 7 | 4.47 | 360.00 |
| 4 | 7.75 | 6 | 4.47 | 360.00 |
| 5 | 7.21 | 5 | 4.47 | 360.00 |
| 6 | 6.83 | 4 | 4.47 | 360.00 |
| 7 | 6.55 | 3 | 4.47 | 360.00 |
| 8 | 6.32 | 2 | 4.47 | 360.00 |
| 9 | 6.15 | 1 | 4.47 | 360.00 |

These values correspond to the following curve for let-through current I2T:

9.25.6.17 Register description

9.25.6.17.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

1) The offset specifies the position of the register within the CAN object.

9.25.6.17.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.25.6.17.3.2 CAN I/O bus controller

The module occupies 4 analog logical slots on CAN I/O.

9.25.6.17.4 Configuration

9.25.6.17.4.1 Configuration

Name:

Configuration01 to Configuration04

These registers can be used to configure the four DC motors.

The following placeholders are used in the configuration table:

| Register | Channel N | In1 | In2 |
|-----------------|-----------|------|------|
| Configuration01 | 1 | DI3 | DI4 |
| Configuration02 | 2 | DI7 | DI8 |
| Configuration03 | 3 | DI11 | DI12 |
| Configuration04 | 4 | DI15 | DI16 |

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|---------|---|
| 0 - 1 | Configuration of the latch function for ABR counter N. Enabling the latch function is described in the control register (bit 2): | 00 | ABR counter N is latched unconditionally (default setting). The reference enable input is ignored. (Bus controller default setting) |
| | | 01 | ABR counter N is latched if a rising edge occurs on digital input In1 and reference enable input In2 is "1". The reference enable input must be enabled to do this (see bit 2). |
| | | 10 | ABR counter N is latched if a falling edge occurs on digital input In1 and reference enable input In2 is "1". The reference enable input must be enabled to do this (see bit 2). |
| | | 11 | The latch function is disabled. |
| 2 | Reference enable input: | 0 | No reference enable input (bus controller default setting) |
| | | 1 | Digital input In2 is used as a reference enable input |
| 3 | Active level of the reference enable input for ABR counter N: | 0 | Active level = High (bus controller default setting) |
| | | 1 | Active level = Low |
| 4 | Reserved | 0 | |
| 5 - 7 | Definition of limit switch N (see also "Limit switch function" on page 2588): | 000 | Limit switch N is disabled (bus controller default setting) |
| | | 001 | Digital input In1 is used as the Enable input . ¹⁾ |
| | | 010 | Digital input In1 is used as the limit switch |
| | | 011 | Reserved |
| | | 100 | Digital input In2 is used as the limit switch |
| | | 101 | Reserved |
| | | 110 | Digital inputs In1 and In2 are used as left and right limit switches |
| | | 111 | Reserved |
| 8 | Active level for limit switch N: | 0 | Active level = High (bus controller default setting) |
| | | 1 | Active level = Low |
| 9 - 10 | Trigger input for trigger counter "usSinceTrigger" N: | 00 | The trigger counter is disabled (bus controller default setting). |
| | | 01 | Digital input In1 is used as trigger input |
| | | 10 | Digital input In2 is used as trigger input |
| | | 11 | Reserved |
| 11 | Display of current average for output N: | 0 | If the corresponding setting has been enabled, then the average current value is indicated in register "CounterLatch[x]" on page 2596 (see bit 5 in the "control register" on page 2589) (bus controller default setting) |
| | | 1 | If the corresponding setting has been activated, then the average current value is shown in the "usSinceTrigger[x]" on page 2596 register (see bit 5 in the "control register" on page 2589). |
| 12 + 15 | Output mode N: | 00 | PWM mode (bus controller default setting) |
| | | 01 | Current mode |
| | | 10 | Boost-and-hold current control ¹⁾ |
| | | 11 | Reserved |
| 13 - 14 | Decay configuration for PWM N (see also "Decay configuration" on page 2599): | 00 | Slow decay (bus controller default setting) |
| | | 01 | Mixed decay |
| | | 10 - 11 | Reserved |

1) Only available with firmware version 102 or later

Limit switch function

The limit switch function serves to quickly shut off the PWM outputs when a limit position is reached.

The limit switch is activated and the disable edge (rising or falling) on the limit switch input is selected using bits 6 to 8.

A PWM output is deactivated as soon as the configured disable edge is reached on the corresponding input of the limit switch. This deactivation occurs independently of the current direction of movement. It remains deactivated until either the limit switch function is deactivated or the limit switch is acknowledged with bit 4 in the respective "control register" on page 2589.

Enable input

The limit switch input of the module can optionally be used as an enable input. Bits 5 to 7 must be configured accordingly for this. Data point [OutputEnable](#) and the digital input are logically linked by an AND operator.

When the enable input is enabled, the PWM output can be switched on and off via the digital input. Switching on and off is done with a jitter of 50 µs. Since it is possible to react only at the beginning of the PWM period, an additional jitter of the length of the [PWM period duration](#) must be taken into account.

9.25.6.17.4.2 Control

Name:

TriggerEdge01 to TriggerEdge04
 StartTrigger01 to StartTrigger04
 StartLatch01 to StartLatch04
 DitherDisable01 to DitherDisable04
 ClearError01 to ClearError04
 ShowMeanCurrent01 to ShowMeanCurrent04
 ResetCounter01 to ResetCounter04
 OutputEnable01 to OutputEnable04

These registers can be used to configure the behavior of the trigger, the ABR counter and the dither.

[N] stands for the index number of the register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|--|-------|--|
| 0 | TriggerEdgeN Configuration of trigger edge for "usSinceTrigger": | 0 | Counting starts at rising edge |
| | | 1 | Counting starts at falling edge |
| 1 | StartTriggerN Enabling of "usSinceTrigger" due to a status change of bit 1 | x | Counting starts at the next trigger edge (see bit 0). For more information about trigger functionality, see " Trigger function procedure " on page 2589. |
| | | | |
| 2 | StartLatchN Latching or referencing ABR counters: | 0 | Disabled |
| | | 1 | Enabled |
| 3 | DitherDisable N | 0 | Dither for PWM output N is switched on. The dither frequency and dither amplitude must be greater than 0 (see " Dither " on page 2593). |
| | | 1 | Dither for PWM output N is switched off. |
| 4 | ClearErrorN Acknowledging error or limit switch: | 0 | No effect |
| | | 1 | Error acknowledgment on output N (overcurrent or open load) or acknowledgment of limit switch N |
| 5 | ShowMeanCurrentN Konfiguration der Register "CounterLatch" on page 2596 und "usSinceTrigger" on page 2596 | 0 | Register CounterLatchN contains the latched counter value. Register usSinceTriggerN contains the trigger counter. |
| | | 1 | Both registers contain the current PWM output current |
| 6 | ResetCounterN Reset ABR counter | 0 | Enable ABR counter |
| | | 1 | Reset ABR counter |
| 7 | OutputEnableN ¹⁾ | 0 | Switch off the PWM output |
| | | 1 | Switch on the PWM output |

1) Only for boost-and-hold current control.

Trigger function procedure

The following points must be taken into consideration when configuring or activating the trigger function:

- Select the desired trigger edge using bit 0
- Enable the trigger function by changing the state of StartTrigger (bit 1). This edge clears the register [usSinceTrigger](#) (µs counter).
- When the trigger event occurs, the µs counter "usSinceTrigger" is started
- The "usSinceTrigger" counter cannot overrun, i.e. the counter is stopped at $2^{16}-1$ and retains this value until the next time the trigger function is activated
- The trigger function can be re-activated at any time by changing the state of StartTrigger (bit 1) regardless of if a trigger event has occurred or if "usSinceTrigger" has reached its maximum value.

Reset ABR counter

Bit 6 sets the following counters and status bits to 0:

- ABR counter
- Latch value of the ABR counter
- Latching started on the ABR counter (bit 4 of the "status register" on page 2597)
- ABR counter successfully latched (bit 5 of the "status register" on page 2597)

Please note that a started latch procedure is no longer active after the ABR counter has been reset. This means that latching must be restarted by a rising edge on bit 2.

OutputEnable

Bit 7 can start or stop the output profile in [Boost-and-Hold Betrieb](#). If a rising edge occurs on this data point, any pending [Overcurrent error](#) or [Open load error](#) of the associated PWM output are acknowledged and the output is switched on.

Starting or stopping occurs immediately after the transfer of the value on the X2X Link network with a jitter of 50 µs. Note that during startup, an additional jitter of the length of the [PWM period duration](#) of the current controller is added.

Starting and stopping the output profile can also be controlled by the digital input. See ["Enable input" on page 2589](#).

9.25.6.17.4.3 Difference between operating modes

The module provides the following operating modes:

- PWM mode
- Current mode
- Boost-and-hold current control

The following images illustrate how the current curves for the outputs are affected by registers "PWM period duration" on page 2595 and "PWM pulse width" on page 2595.

PWM mode

At the beginning of each period, the output is switched on for the percentage of time set in the PWM pulse width.

Current mode

At the beginning of each period, the current output is switched on. After reaching the value set in "PulseWidthCurrentPWM" on page 2595, the output is switched off and the voltage drops according to the set decay configuration until it is next switched on.

Boost-and-hold current control

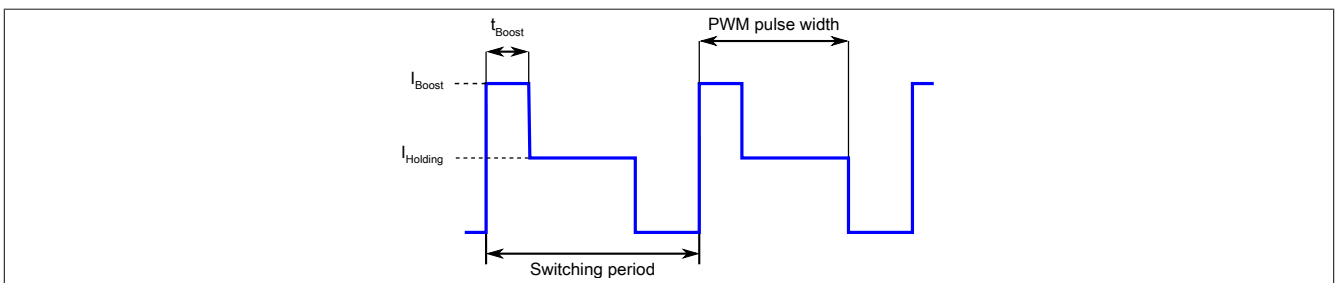

Information:

Only available with firmware version 102 or later.

In this operating mode, the current mode is combined with a higher-level PWM mode.

After the time (t_{Boost}) set in register "BoostTime" on page 2592, the inrush current (I_{Boost}) is changed to the holding current ($I_{Holding}$) specified in register "HoldingCurrent" on page 2592.

The period duration of the current profile is set in register "SwitchingPeriod" on page 2592 in 50- μ s steps. In addition, the PWM period duration must be set in register PeriodDurationPWM. (Not shown, see Current mode.)

Example: Controlling a digital valve

The boost current (I_{Boost}) is used to quickly open a digital valve, for example. After the boost time (t_{Boost}), the current is reduced to the lower holding current (I_{Holding}) in order to save energy and not overload the PWM output. I_{Holding} is therefore set to a smaller value than I_{Boost} .

The pulse width can be used to set the opening time of the valve in relation to the period duration. After the period duration has expired, I_{Boost} is started again. If the valve should remain open continuously, the pulse width must be set to 100%. In this case, no boost current is output at the beginning of the next period.

I_{Boost} is only output if the valve has been switched off for at least 50 μs . If the pulse width is set smaller than t_{Boost} , the boost time is shortened accordingly.

9.25.6.17.4.4 Boost-and-hold registers**Boost current**

Name:

BoostCurrent01 to BoostCurrent04

The boost current is set in mA in this register.

| Data type | Values | Information |
|-----------|------------|---------------|
| INT | 0 to 10000 | For 0 to 10 A |

Boost time

Name:

BoostTime01 to BoostTime04

The sampling time is set in μs in this register. The entered value is rounded up to the next largest 50- μs interval.

| Data type | Values | Information |
|-----------|------------|------------------|
| UINT | 0 to 65500 | In μs |

Holding current

Name:

HoldingCurrent01 to HoldingCurrent04

The holding current is set in mA in this register. After the boost time, the current for the remaining pulse width time is raised or lowered to this value.

| Data type | Values | Information |
|-----------|-----------|--------------|
| INT | 0 to 6000 | For 0 to 6 A |

Period duration of the current profile

Name:

SwitchingPeriod01 to SwitchingPeriod04

This register is used to set the period duration of the current profile in μs for boost-and-hold mode. The entered value is rounded up to the next largest 50- μs interval.

| Data type | Values | Information |
|-----------|---------------|--------------------------------|
| UINT | 2000 to 65500 | Corresponds to 500 to 15.26 Hz |

Synchronous operation of channels

In order for 2 or more channels to run synchronously, their period durations of the output profile ([SwitchingPeriod](#)) must be set to the same value or to a multiple of the other channel. An exact phase position of 0 degrees can only be guaranteed if the channels are switched on simultaneously (in the same bus cycle) with [OutputEnable](#).

To operate the current profile synchronously to the X2X Link network, [SwitchingPeriod](#) should be set to a multiple of the bus cycle.

9.25.6.17.4.5 Dither

When the position setpoint for valves remains constant for a long period of time, especially in fluids, there is a risk that a valve will stick. This is normally prevented using "dithering". When doing so, the value is permitted to slightly oscillate around the position setpoint.

By default, the dither is active for both outputs as soon as the **dither amplitude** and **dither frequency** are set to a value >0. If necessary, the dither can be disabled for each output individually or simultaneously (see bit 3 in register "control register" on page 2589).

No dither is used in boost-and-hold mode of the PWM output. Any set dither amplitude and dither frequency are ignored by the module.

Dither amplitude

Name:

ConfigOutput01

This register can be used to configure the amplitude value or pulse width.

| Data type | Value | Information |
|-----------|----------|---|
| USINT | 0 to 255 | Current mode: 0 to 25.5% of the module's nominal current ¹⁾ PWM mode: 0 to 25.5% of the period duration. Bus controller default setting: 0 |

1) See the technical data for the module.

Dither frequency

Name:

ConfigOutput02

This register can be used to set the frequency in 2 Hz steps.

| Data type | Value | Information |
|-----------|----------|--|
| USINT | 0 to 255 | Corresponds to 0 to 510 Hz. Bus controller default setting: 0 |

Dither example

The values specified in the data sheet for a valve should be used to calculate [Dither amplitude](#) and [Dither frequency](#).

Data sheet for the valve

The data sheet for a valve manufacturer recommends the following dithering:

Dither height in percent (A_{Dither}): 20 to 35% (peak values) of the nominal valve current of 2 A

Dither frequency in Hertz (F_{Dither}): 40 to 70 Hz

Selected values

These values correspond to the average values on the valve data sheet.

$A_{\text{Dither}} = 27\%$ of the valve's nominal current (peak values)

$F_{\text{Dither}} = 56 \text{ Hz}$

Formulas

[Dither amplitude](#) = $(A_{\text{Dither}} / 2) * (\text{Nominal current}_{\text{Valve}} / \text{Nominal current}_{\text{Module}}) * 10$

Info: $(A_{\text{Dither}} / 2)$ = Conversion of the peak values to amplitude, " * 10" = Scaling of the dither amplitude to 1/10%

[Dither frequency](#) = $F_{\text{Dither}} / 2 \text{ Hz}$

Info: Dither frequency is configured in 2 Hz steps.

Calculation

By using the selected values in the formulas.

[Dither amplitude](#) = $27\% / 2 * (2 \text{ A} / 6 \text{ A}) * 10 = 45$

[Dither frequency](#) = $56 \text{ Hz} / 2 \text{ Hz} = 28$

9.25.6.17.5 Communication

9.25.6.17.5.1 PWM pulse width

Name:

PulseWidthCurrentPWM01 to PulseWidthCurrentPWM04

The PWM pulse width (PWM mode) or current setting (in current mode) is entered in this register according to the setting in the module configuration register. (see also ["Difference between operating modes" on page 2591.](#)) A negative value changes the output polarity.

PWM mode

| Data type | Value | Output + | Output - |
|-----------|--------|--------------------------------------|--------------------------------------|
| INT | 32767 | High | Low |
| | 16384 | PWM 50/50 | Low |
| | 0 | Low (bus controller default setting) | Low (bus controller default setting) |
| | -16384 | Low | PWM 50/50 |
| | -32767 | Low | High |

Current mode

| Data type | Value | Current mode |
|-----------|------------------|------------------------|
| INT | 19661 to 32767 | 6 to 10 A (max. 2 s) |
| | 19660 | 6 A |
| | 0 | 0 A |
| | -19660 | -6 A |
| | -19661 to -32767 | -6 to -10 A (max. 2 s) |

Boost-and-hold current control

In this operating mode, this register is used to control the pulse width of the output signal in a way similar to PWM mode. In contrast, the pulse width of the current profile is specified. See ["Current mode" on page 2591.](#)

In this operating mode, the pulse width can be set with a resolution of 50 μ s. The pulse width of the current is specified as a percentage of the period duration of output signal [SwitchingPeriod](#). If the value of this register is modified during a period, the pulse width is immediately adjusted.

Negative values correspond to an output with negative current direction.

| Data type | Values | Information |
|-----------|-----------------|-------------------|
| INT | -32768 to 32767 | For -100% to 100% |

Resolution/Derating

As mentioned earlier in the technical data, the PWM resolution is 15-bit (+ sign). This value is derated for a period duration of less than 328 μ s because of the minimal PWM timing resolution (10 ns) (see following diagram). With the minimum PWM period duration of 20 μ s, the PWM has 11-bit resolution (+ sign):

9.25.6.17.5.2 PWM period duration

Name:

PeriodDurationPWM

This register can be used to set the period duration between 20 μ s (50 kHz) and 65535 μ s (15 Hz). See also ["Difference between operating modes" on page 2591.](#)

| Data type | Value | Information |
|-----------|-------------|-----------------|
| UINT | 20 to 65535 | Time in μ s |

9.25.6.17.5.3 ABR counter

Name:

Counter01 to Counter04

These registers are 16-bit AB(R) counters.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.6.17.5.4 ABR counter latch

Name:

CounterLatch01 to CounterLatch04

When a latch event occurs, the current counter values are saved in these registers. For additional features, see bit 5 in the respective "control register" on page 2589.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.6.17.5.5 Microseconds since trigger

Name:

usSinceTrigger01 to usSinceTrigger04

This register shows either the time in μs since the last trigger event or the average current value.

- The usSinceTrigger counter cannot overrun, i.e. the counter is stopped at $2^{16}-1$ and retains this value until the next time the trigger function is activated.
- If the average current is displayed in this register (bit 11 in the respective "configuration register" on page 2588), then the data type of usSinceTrigger in Automation Studio must be unsigned integer (UINT). The average current value, on the other hand, is an Integer (INT). This means that negative currents are displayed between 32,769 and 65,535.

Counting mode

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Measurement of average current value

| Data type | Value | Information |
|-----------|------------------|---------------------------------------|
| INT | 19,661 to 32,767 | 6 to 10 A |
| | 19,660 | 6 A |
| | 1 | 305 μA (= 10 A / 32,767) |
| | 0 | 0 A |
| | 65,535 | -305 μA (= -10 A / 32,767) |
| | 45,876 | -6 A |
| | 45,875 to 32,769 | -6 to -10 A |

9.25.6.17.5.6 Status of the inputs

Name:

StatusInput01 to StatusInput16

nLatchPending01 to nLatchPending04

LatchDone01 to LatchDone04

EndswitchReached01 to EndswitchReached04

PWMError01 to PWMError0

These registers contain the status of the inputs and outputs for each DC motor.

The following placeholders are used in the status table.

| Register | Channel [N] | In1 | In2 | In3 | In4 |
|--------------------|-------------|------|------|------|------|
| Status of inputs 1 | 1 | DI1 | DI2 | DI3 | DI4 |
| Status of inputs 2 | 2 | DI5 | DI6 | DI7 | DI8 |
| Status of inputs 3 | 3 | DI9 | DI10 | DI11 | DI12 |
| Status of inputs 4 | 4 | DI13 | DI14 | DI15 | DI16 |

| Data type | Values |
|---------------------|------------------------|
| USINT ¹⁾ | See the bit structure. |
| UINT ²⁾ | See the bit structure. |

1) Function model 0 and function model 254 → Registers "Status of inputs 3" and "Status of inputs 4"

2) Only function model 254 → Registers "Status of inputs 1" and "Status of inputs 2"

Bit structure:

| Bit | Description | Value | Information |
|--------|--------------------------------|-------|---|
| 0 | StatusInput [In1] | x | In1 is used with ABR counter N for encoder signal A. |
| 1 | StatusInput [In2] | x | In2 is used with ABR counter N for encoder signal B. |
| 2 | StatusInput [In3] | 0 | Possible uses of the digital input <ul style="list-style-type: none"> • Trigger input N • Reference pulse for ABR counter N • Limit switch N (left) |
| 3 | StatusInput [In4] | 0 | Possible uses of the digital input <ul style="list-style-type: none"> • Reference enable N • Trigger input N • Limit switch N (right) |
| 4 | nLatchPending [x] | 00 | Latching is started. |
| | | 01 | ABR counter latch N is ready. Latch not yet started. |
| 5 | LatchDone [x] | 0 | After each successful latch of ABR counter N, the status of this bit is changed. |
| 6 | EndswitchReached [x] | 00 | No effect on PWM output N |
| | | 01 | Limit switch N is reached. PWM output N is switched off. |
| 7 | PWMError [x] | 0 | No channel error |
| | | 1 | Channel error occurred. PWMError [x] is a summary of the two error bits CurrentError0x and OverCurrentError0x in register "Channel errors" on page 2598. PWMError [x] is not affected by the error flags contained in the "global errors" on page 2599 register. In order to intercept error states that can affect the PWM outputs, the global errors register must also be monitored. |
| 8 - 15 | Function model 254 only | | |
| | Status of inputs 1 | x | With "Status of inputs 1", bits 12 to 15 contain error bits 4 to 7 of register "Global error" on page 2599. |
| | Status of inputs 2 | x | With "Status of inputs 2", bits 8 to 15 contain error bits 0 to 7 of register "Channel errors" on page 2598. |

9.25.6.17.5.7 Channel errors

Name:

CurrentError01 to CurrentError04

OverCurrentError01 to OverCurrentError04

If an error is detected, the corresponding error bit in this register remains set until the error is acknowledged using bit 4 in the respective "control register" on page 2589.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|--------------------|-------|--|
| 0 | CurrentError01 | 0 | No error |
| | | 1 | Open load error |
| 1 | OverCurrentError01 | 0 | No error |
| | | 1 | Overcurrent error, output deactivated. |
| 2 | CurrentError02 | 0 | No error |
| | | 1 | Open load error |
| 3 | OverCurrentError02 | 0 | No error |
| | | 1 | Overcurrent error, output deactivated. |
| 4 | CurrentError03 | 0 | No error |
| | | 1 | Open load error |
| 5 | OverCurrentError03 | 0 | No error |
| | | 1 | Overcurrent error, output deactivated. |
| 6 | CurrentError04 | 0 | No error |
| | | 1 | Open load error |
| 7 | OverCurrentError04 | 0 | No error |
| | | 1 | Overcurrent error, output deactivated. |

Overcurrent error

An overcurrent error is registered if one of the following conditions is met:

- ≥ 10 A flow from a PWM output for at least 2 seconds
- ≥ 16 A flow for 3 consecutive PWM cycles
- All PWM outputs together consume more than 32 A on the X3 connector

In all three cases, the affected PWM output is deactivated by the firmware (i.e. the pins on the PWM output are short-circuited). The user must acknowledge the error using bit 4 in the respective "control register" on page 2589 before a PWM output deactivated in this manner can be made operational again.

Open load error

An open load error is only registered in current control mode (see bit 12 in the respective "configuration register" on page 2588) if the current setpoint is not reached. In some cases this can be caused by an open line, although usually the impedance of the load is too high.

9.25.6.17.5.8 Global error

Name:

OverVoltageError

UnderVoltageError

VoltageWarning

OvertemperatureError

This register indicates overtemperature and errors in the module supply. The error bits are automatically acknowledged by the module as soon as the values are back within the permissible limits.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------------|-------|--|
| 0 - 3 | Reserved | 0 | |
| 4 | OverVoltageError | 0 | No error |
| | | 1 | Voltage >80 V. All outputs are deactivated. |
| 5 | UnderVoltageError | 0 | No error |
| | | 1 | Voltage <18 V |
| 6 | VoltageWarning | 0 | No error |
| | | 1 | Voltage >60 V |
| 7 | OvertemperatureError | 0 | No error |
| | | 1 | Module overtemperature; all outputs are deactivated. |

9.25.6.17.5.9 Temperature

Name:

ModuleTemperature

The module temperature is displayed in this register.

| Data type | Value | Information |
|-----------|------------|--------------------------|
| SINT | -40 to 125 | Module temperature in °C |

9.25.6.17.6 Decay configuration

The decay configuration determines the method and dynamics of current reduction for inductive loads or motors.

"Slow decay" is configured by default. In this mode, the current is automatically reduced relatively slowly with resistance in the load. No energy is regenerated into the module.

"Mixed decay" mode is recommended for applications that require a dynamic and linear reduction of current. In this mode, energy is regenerated into the module during part of the PWM cycle (fast decay).

9.25.6.17.6.1 Current control

As its name suggests, mixed decay mode is a mix of "slow decay" and "fast decay". This occurs as follows:

A check is made at the beginning of each PWM cycle to determine if the actual current for the phases is below the set current. If this is the case, PWM is enabled (On) until the current setpoint is reached. If the current setpoint has already been exceeded at the beginning of the PWM cycle (generator operation), the system immediately switches to fast decay mode until the current setpoint is exceeded. The rest of the PWM cycle always takes place in slow decay mode.

This also permits generator operation as long as the valid range for the supply voltage has not been exceeded due to the regeneration into the DC circuit.

Current control in Mixed Decay mode

Current control in Slow Decay mode

9.25.6.17.6.2 PWM control

When Mixed Decay mode is enabled, the outputs are driven in Fast Decay mode up until 50% of the period and in Slow Decay mode for the remainder of the switch-off phase.

When Slow Decay mode is used, it is immediately enabled during the switch-off phase.

PWM control in Mixed Decay mode (pulse duty factor = 37.5%)

PWM control in Slow Decay mode (pulse duty factor = 37.5%)

Operating DC motors

In PWM mode, the motor current is limited to the maximum current (10 A), independent of the supply voltage.

However, the motor switches to generator operation when braking. Because of the counter EMF, which is dependent on the rotary speed, a current is generated in the module that is only limited by the internal resistance of the motor. This is not permitted to exceed 15 A (maximum 2 seconds).

The counter EMF closely corresponds to the voltage needed to achieve this speed. Therefore, the maximum brake current is very easy to calculate with the following formula.

$$I_{\text{Brake}} = U_e * \frac{\text{Pulse width}}{100\%} * \frac{1}{R_{\text{Motor}}}$$

Example:

| | |
|------------------------------|----------------------|
| Module supply | 42 V |
| Pulse width | 16364 (equal to 50%) |
| Internal resistance of motor | 3.5 Ω |

$$I_{\text{Brake}} = 38\text{V} * \frac{50}{100\%} * \frac{1}{3.5\Omega} = 5.4\text{A}$$

9.25.6.17.7 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| |
|---------------------------|
| Minimum cycle time |
| 400 μs |

9.25.6.17.8 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| |
|--------------------------------|
| Minimum I/O update time |
| 400 μs |

9.25.7 X20SM1426

Data sheet version: 1.51

9.25.7.1 General information

The stepper motor module is used to control stepper motors with a rated voltage of 24 VDC at a motor current up to 1 A (1.2 A peak). Additionally, this module has four digital inputs that can be used as limit switches or as encoder inputs.

Due to the individual adjustment of the coil currents, the motor is only operated with the current it actually needs. This simplifies the selection of the available motors and prevents unnecessary heating. Because this affects energy consumption and thermal load, the effects are positive on the service life of the complete system. Complete flexibility is achieved through the use of independently adjustable holding, maximum and nominal current values. The current for microsteps is automatically adjusted to the configured current values.

The automatic motor identification system is an enormous help during standstills. The stepper motor modules can identify the connected motors using their coil characteristics and generate feedback in the form of an analog value. This makes it possible to detect not only wiring errors, but also incorrect motor types being used mistakenly. A stall detection mechanism is integrated to analyze the motor load. Detection of the stall is defined via a configurable threshold. This allows an overload or motor standstill to be detected precisely in many different types of applications.

- 1 stepper motor, 24 VDC, 1 A (1.2 A peak)
- Resolution of current values at 1%
- Maximum, rated and holding current configured independent of each other
- 38.5 kHz PWM frequency
- Integrated motor detection
- 256 micro-steps
- Stall detection
- Complete integration in Automation Studio and CNC applications
- 4 inputs, 24 VDC, can be configured as ABR
- Ramp function model based on the CANopen communication profile DS402
- NetTime timestamp: Position change, trigger time

NetTime timestamp of the position and trigger time

It is not just the position value that is important for highly dynamic positioning tasks, but also the exact time the position is measured. The module is equipped with a NetTime function for this that supplies a timestamp for the recorded position and trigger time with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.25.7.2 Order data

9.25.7.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|-------|-----------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset state |
| | e + r | | Red on / Green single flash | Invalid firmware |
| | 1 - 4 | | Green | Input state of the corresponding digital input |
| | M | | Orange | On |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.25.7.5 Pinout

In accordance with the EN 60204-1 standard, a cable cross section of 0.75 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 1.2 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

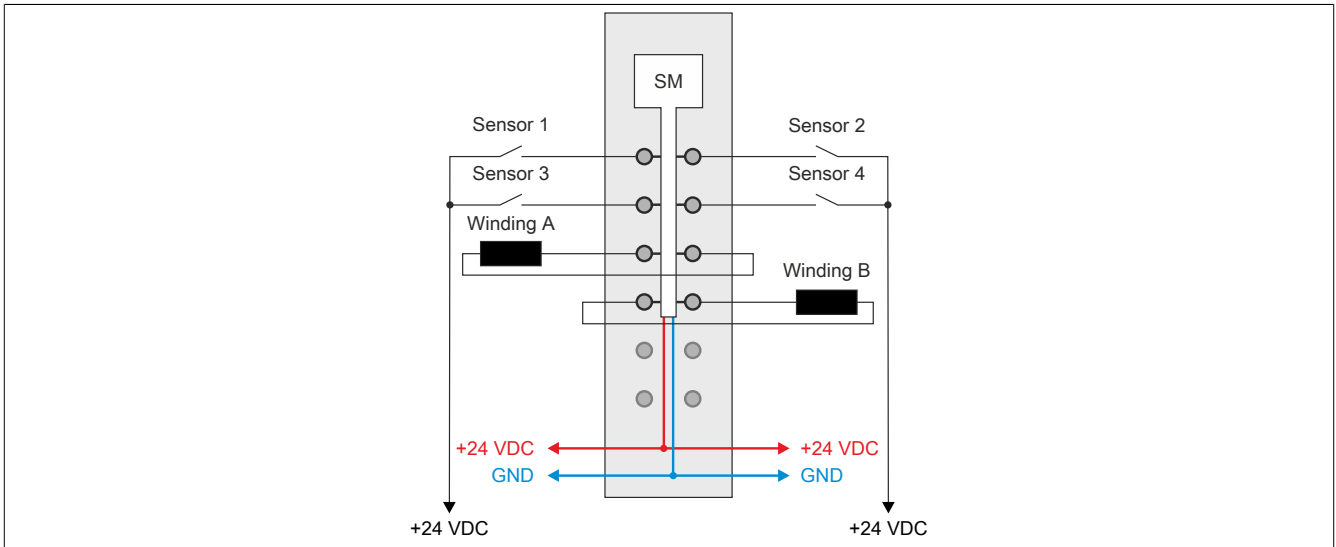

The terminal block is not permitted to be plugged in or unplugged during operation.

Information:

Shielded motor cables must be used in order to meet the limits according to the EN 55011 standard (emissions).

9.25.7.6 Connection example

9.25.7.7 Connection options for digital inputs

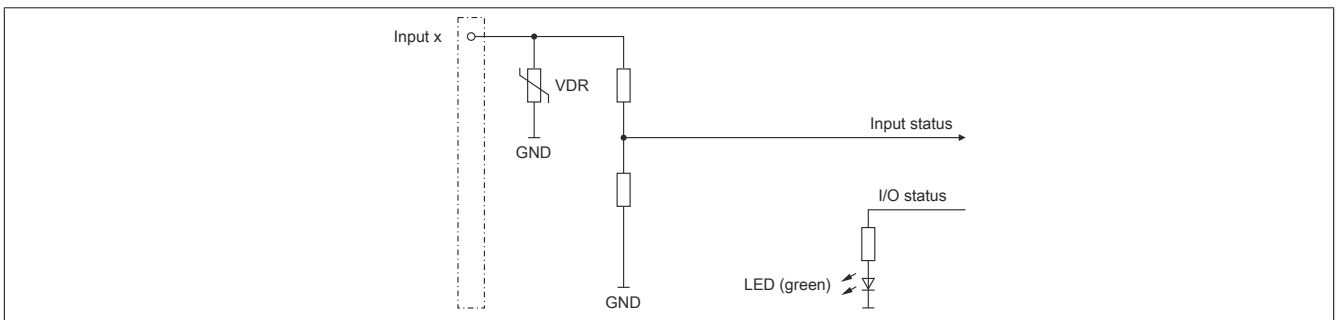

Function model "Standard"

| Channel | Function | | |
|---------|---------------|--|---------------|
| DI 1 | Digital input | | A |
| DI 2 | Digital input | | B |
| DI 3 | Digital input | | R |
| DI 4 | Digital input | | Trigger input |

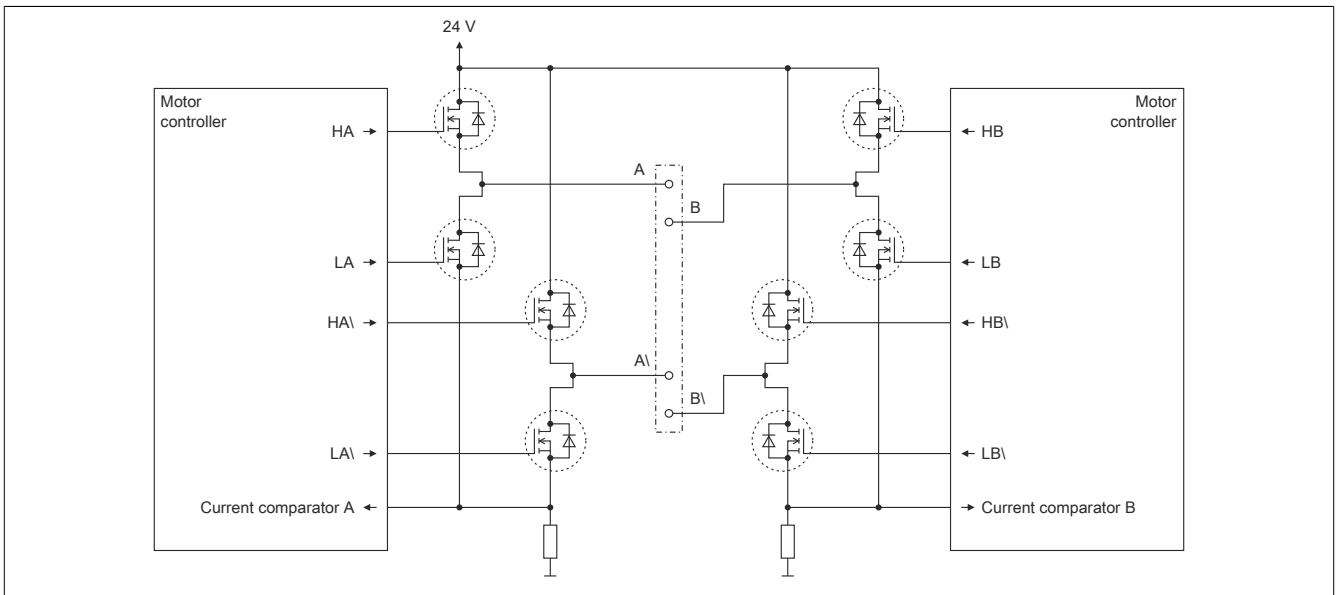

Function model "Ramp"

| Channel | Function | | |
|---------|---------------|---------------|-----------------------|
| DI 1 | Digital input | A | A |
| DI 2 | Digital input | B | B |
| DI 3 | Digital input | R | Negative limit switch |
| DI 4 | Digital input | Digital input | Positive limit switch |

9.25.7.8 Input circuit diagram

9.25.7.9 Output circuit diagram

9.25.7.10 Overvoltage cutoff

The module supply voltage is continually monitored. Its status can be read. The error "Module power supply error" occurs when the voltage is above or below the limits.

If the supply voltage on the module rises or falls outside the limit values (e.g. due to regeneration), then the motor output is switched off. The outputs are reactivated as soon as the supply voltage is back in the valid range and the error bit is reset.

Supply voltage limit values

| | Drive is switched off | Drive is switched back on |
|-------------|-----------------------|---------------------------|
| Lower limit | <17.5 V | >19.5 V |
| Upper limit | >30 V | <29.0 V |

9.25.7.11 Shutdown in the event of overtemperature (starting at 85°C)

If the module temperature reaches or overshoots the limit value of 85°C, the module performs the following actions:

- Sets the "overtemperature" error bit
- Cuts off the outputs (short-circuited)

As soon as the temperature is reduced below 85°C again, the error must be acknowledged with "OvertemperatureAcknowledge" so that the channels can be switched on again.

9.25.7.12 Derating

Only modules with a maximum power dissipation of 1 W are permitted to be operated next to the SM module. To ensure proper operation, observe the derating values listed below.

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

Power dissipation derating for neighboring modules

Modules directly next to the SM module can have a power loss of 1 W. If the SM module is operated at the rated load over the entire temperature range (1 A rated current), the power loss of neighboring modules must be derated starting at 45°C.

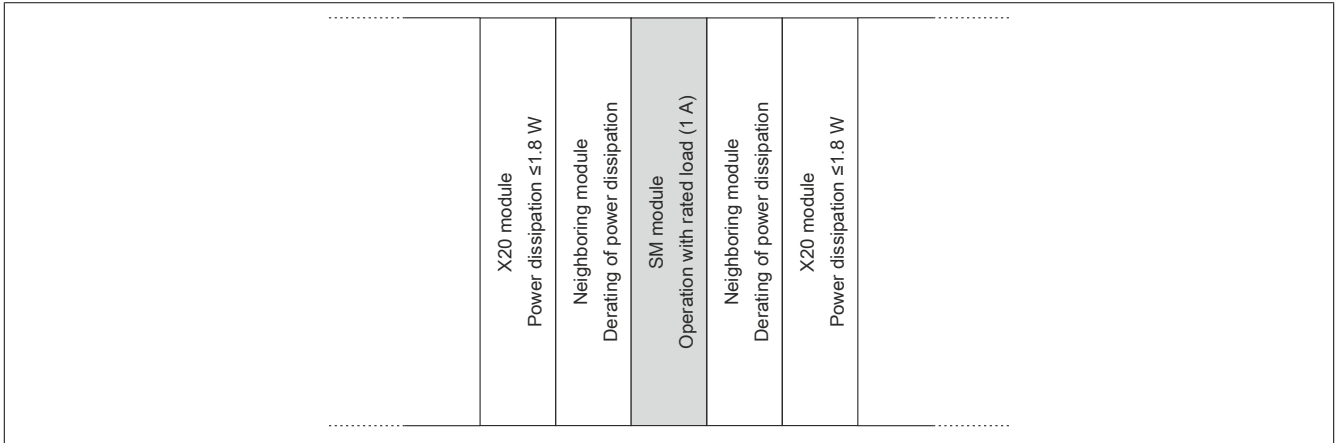

Figure 171: Operating the SM module over the entire temperature range at 1.0 A rated current

Figure 172: Power loss derating for directly neighboring modules

Current derating of the SM module

If the power loss of the neighboring modules to the SM module is 1 W, then the current of the SM module must be derated starting at 45°C.

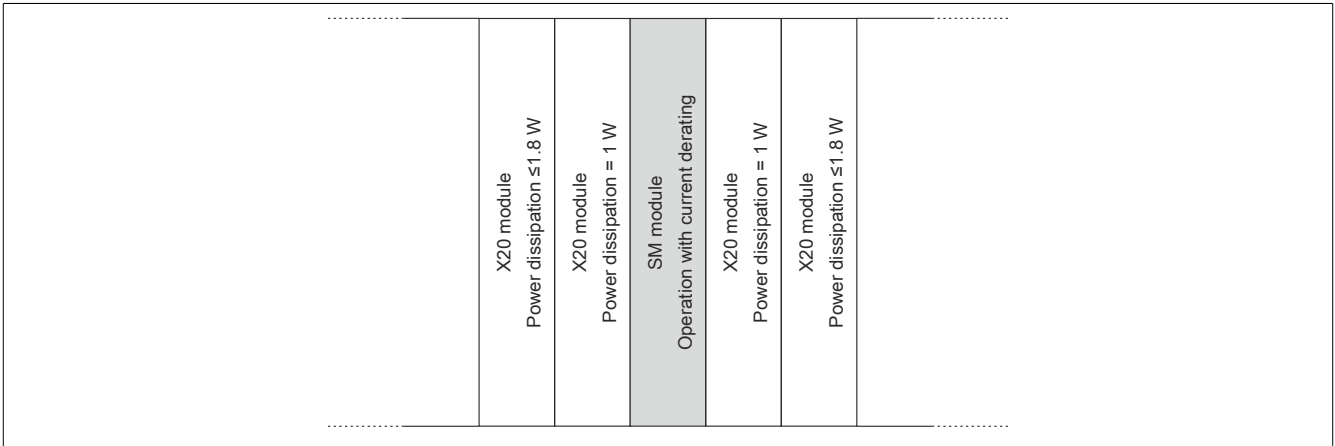

Figure 173: Neighboring modules to the SM module have a power loss of 1.0 W

Figure 174: Current derating

Current derating for multiple SM modules

If three or more SM modules are operated in a cluster, the current of the SM modules must be derated as follows starting at 40°C.

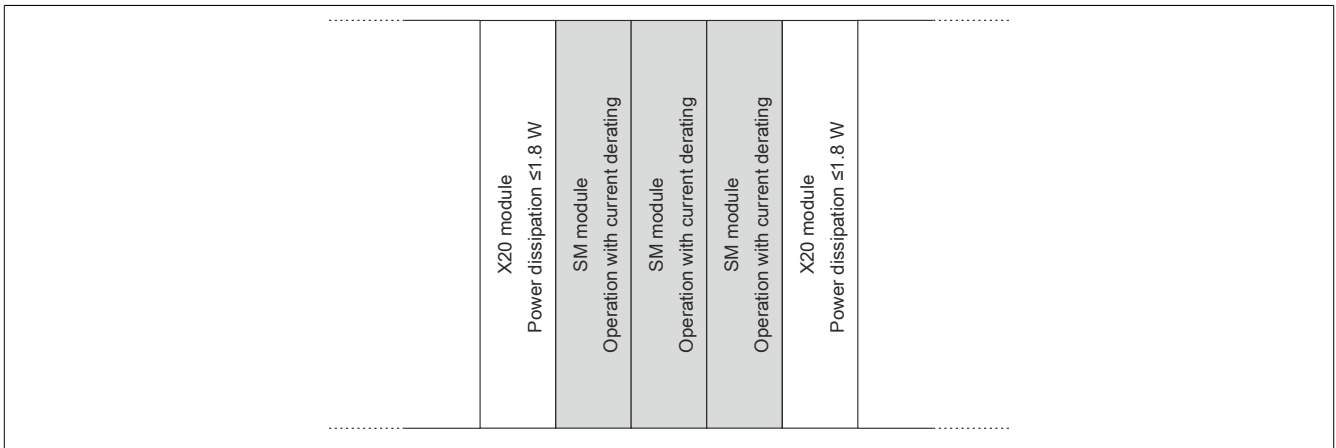

Figure 175: Operating three or more SM modules in a cluster

Figure 176: Current derating

9.25.7.13 Register description

9.25.7.13.1 mapp Motion system requirements

This module can be operated with mapp Motion function blocks. The following minimum versions are required for this:

- Upgrade version 2.2.0.0
- Automation Studio 4.7.2
- Automation Runtime 4.72

9.25.7.13.2 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

1) The offset specifies the position of the register within the CAN object.

9.25.7.13.5.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "Using I/O modules on the bus controller" on page 3789.

9.25.7.13.5.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.25.7.13.6 Register description: Function model "Standard", general registers

9.25.7.13.6.1 Configuration registers

Stall threshold

Name:

ConfigOutput01

The SM module features integrated sensorless load measurement for the motor axis. This is especially useful for detecting a "stall condition" (e.g. if the motor moves to the end point during a homing procedure). It cannot be used for torque monitoring during dynamic movements.

With the "stall threshold" register, a threshold can be defined according to the motor load, and the module detects a stall condition started at this threshold (see "[Error status](#)" on page 2622).

This threshold value must be determined on a case-by-case basis, since the results of load measurement are influenced by a variety of factors.

- Motor speed: A higher speed results in higher measurement values
- Speeds that cause motor resonances (which interfere with load measurement) are to be avoided
- Motor accelerations that create a dynamic load (and also affect the measurement) should also be avoided
- It is especially important to be aware that mixed decay mode must be optimized for reliable stall detection (see "[Mixed decay threshold](#)" on page 2616)

The higher the load measurement value, the lower the load. This means that a stall condition is detected if the load measurement value drops below the trigger threshold for stall detection.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------------------------------|--------|--|
| 0 - 2 | Trigger threshold for stall detection | 0 | Stall detection is disabled |
| | | 1 | Minimum sensitivity for stall detection |
| | | 2 to 6 | Setting the sensitivity of stall detection |
| | | 7 | Maximum sensitivity for stall detection |
| 3 - 15 | Reserved | 0 | |

Mixed decay threshold

Name:

ConfigOutput16

The mixed decay threshold is configured in this register. This value must be adjusted according to the motor being used, current and voltage when using [stall detection](#). Otherwise, the default value 15 will be used.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|-----------------------|---------|-----------------------------------|
| 0 - 3 | Mixed Decay Threshold | 0 | Mixed decay disabled |
| | | 1 to 14 | Setting for mixed decay threshold |
| | | 15 | Mixed decay always enabled |
| 4 - 15 | Reserved | - | |

Mixed decay modules provide a greatly optimized sinusoidal current profile in the individual phases of the stepper motor, especially for fast current changes and low current values.

Mixed decay interferes with reliable stall detection, however. For this reason, mixed decay mode can be disabled during stall detection (motor load measurement) using the mixed decay threshold. The smaller the configured mixed decay threshold, the larger the range in which mixed decay is disabled while motor load measurement takes place.

Mixed decay mode is always enabled if the mixed decay threshold is set to 15.

Relationship between stall detection and mixed decay

Depending on the application and the motor used, satisfactorily smooth operation can be achieved while using stall detection by setting the mixed decay threshold to a value between 1 and 14. This is a compromise between smooth operation and stall detection quality and must be fine tuned during commissioning.

Minimum speed for stall detection

Name:

StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled and the configured [mixed decay threshold](#) is used. The value 15 is always used for the mixed decay threshold below this threshold value, and no stall error is reported. This means that mixed decay mode is always enabled at low speeds where stall detection principally does not work.

| Data type | Value | Information |
|-----------|------------|------------------------------------|
| UINT | 0 to 65535 | Minimum speed in steps per second. |

Full step threshold

Name:

FullStepThreshold01

This register configures a rotational speed. When this defined speed has been reached, the drive will automatically change from microsteps to full step mode. This makes it possible to optimize the torque at higher speeds, while microstep mode ensures optimal radial runout at lower speeds.

It does not make sense to change to full step mode at a standstill because fine positioning would then no longer be possible. This is why value "0" does not make sense in the full step threshold register and is interpreted as disabling full step mode (i.e. the motor will always be operated in microstep mode).

| Data type | Values | Information |
|-----------|-------------|-------------------------|
| UINT | 0 | Full step mode disabled |
| | 1 to 65,535 | Steps/second |

Example

Microstep mode should change to full step mode at 500 steps/second. On a motor with 200 steps per revolution, this would be equal to a speed of:

$$T^{-1} = \frac{500 \text{ steps/second}}{200 \text{ steps/revolution}} = 2.5 \frac{\text{revolutions}}{\text{second}} = 150 \text{ min}^{-1}$$

Holding current, rated current and maximum current

Name:

ConfigOutput03 (holding current)

ConfigOutput04 (rated current)

ConfigOutput05 (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

| Register | Description |
|-----------------|---|
| Nominal current | Current during normal operation |
| Maximum current | Should be selected if a higher motor torque is required briefly during acceleration phases. |
| Holding current | The holding current should be used in situations when less torque is required (e.g. at a standstill). This reduces the amount of heat generated by the motor. |

Switching between preset current values (holding current, rated current, maximum current):

| Function model | Switching between preset current values at runtime |
|---------------------------------------|--|
| Default | Using bits 14 and 15 in the registers "Motor StepX" on page 2624 |
| Standard with enabled SDC information | Using the register "Motor current" on page 2629 |

| Data type | Value | Unit |
|-----------|----------|--|
| USINT | 0 to 117 | Percent of the module's rated current <ul style="list-style-type: none"> • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 117% corresponds to the maximum current of the motor bridge power unit listed in the technical data |

Counter configuration

Name:

ConfigOutput09

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------------|-------|--|
| 0 | ABR latch function | 0 | Negative edge: Disable ABR latch function. |
| | | 1 | Positive edge: Enable latch ABR latch function. After a latch event has occurred, the latch function can be started again with a new rising edge. |
| 1 - 2 | Definition of the latch mode | 00 | Latch ABR counter state unconditionally |
| | | 01 | Latch ABR counter state at a positive edge on the R input |
| | | 10 | Latch ABR counter state at a negative edge on the R input |
| | | 11 | Reserved |
| 3 | | 0 | <ul style="list-style-type: none"> • Position sync: Internal position counter • Position async: ABR counter state • Position latched sync: Internal position counter • Position latched async: ABR counter state |
| | | 1 | <ul style="list-style-type: none"> • Position sync: ABR counter state • Position async: Internal position counter • Position latched sync: ABR counter state • Position latched async: Internal position counter |
| 4 - 7 | Reserved | | |

1) These registers are not available in the standard function model with SDC information enabled.

Motor ID trigger

Name:

MotorIdentTrigger

With this register, a measurement of the motor ID can be initiated acyclically (see "[Motor identification](#)" on page 2621). The application must ensure that the conditions for measurement are met (see table "Notes" in register "[Motor identification](#)" on page 2621).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|---|
| 0 | | 0 | No effect |
| | | 1 | Positive edge triggers motor identifier measurement |
| 1 - 7 | Reserved | 0 | |

9.25.7.13.6.2 Registers for reading back the configuration

Reading back the holding current, nominal current and maximum current

ConfigOutput03Read (holding current)

ConfigOutput04Read (nominal current)

ConfigOutput05Read (maximum current)

These registers are used to read the respective current values in percent.

| Register | Description |
|-----------------|--|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases |
| Holding current | Current when motor is at standstill |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 255 | Percentage of module's nominal current (100% corresponds to the nominal current of the motor bridge power unit in the technical data) |

9.25.7.13.6.3 Communication registers

Measuring motor load

Name:
MotorLoad

This register contains the current measured load value for stall detection. Can be used to tune stall detection.

| Data type | Values |
|-----------|--------|
| USINT | 0 to 7 |

Module configuration 1

Name:
ConfigOutput02

The number of transfer values and the resolution of microsteps for the drive can be configured in this register.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|---|
| 0 | The setting for these two bits determines the meaning of bits 2 and 3 in the "Input counter state" on page 2623 register. | x | |
| 1 - 2 | Reserved | 0 | |
| 3 - 4 | Number of transfer values per X2X cycle (See "Motor StepX" on page 2624.) | 00 | 1 x $\Delta s / \Delta t$ (transfer values: MotorStep0) |
| | | 01 | 2 x $\Delta s / \Delta t$ (transfer values: MotorStep0 - MotorStep1) |
| | | 10 | 4 x $\Delta s / \Delta t$ (transfer values: MotorStep0 - MotorStep3) |
| | | 11 | Reserved |
| 5 - 6 | Resolution of microsteps for the following registers: <ul style="list-style-type: none"> • "Motor StepX" on page 2624 • "Position sync/async" on page 2620 | 00 | Resolution: 5 bits (bit 0 - 4) microsteps; 8 bits (bit 5 - 13) full steps |
| | | 01 | Resolution: 6 bits (bit 0 - 5) microsteps; 7 bits (bit 6 - 13) full steps |
| | | 10 | Resolution: 7 bits (bit 0 - 6) microsteps; 6 bits (bit 7 - 13) full steps |
| | | 11 | Resolution: 8 bits (bit 0 - 7) microsteps; 5 bits (bit 8 - 13) full steps |
| 7 - 15 | Reserved | 0 | |

Position sync/async

Name:

PositionSync

Positionasync

Depending on the [Counter configuration](#), these registers can be used to read either the internal position counter or the counter state of the ABR input.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

| Register | Counter configuration | |
|----------------|---------------------------|---------------------------|
| | Bit 3 ... 0 | Bit 3 ... 1 |
| Position sync | Internal position counter | ABR counter |
| Position async | ABR counter | Internal position counter |

Internal position counter

The internal position counter is the position calculated by the SM module (set position). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the register "[Module configuration 1](#)" on page 2619). In the standard function model with SDC, this value is set to "8-bit microsteps" and can not be changed.

Example of the internal position counter format (7-bit micro steps, i.e. set bit 5 and 6 of the module configuration to binary 10):

ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

Motor identification

Name:

Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. After successful measurement, this register contains the time [µs] required to apply a current increase of $\Delta I = 1 \text{ A}$ to a motor winding.

This depends on:

- Operating voltage
- Inductance and resistance of the motor winding

| Notes | |
|-------|---|
| 1) | To achieve reproducible results, the measurement must be made under the following defined conditions: |
| a) | Motor is at standstill. |
| b) | The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: <ul style="list-style-type: none"> • Full steps are divisible by 4. • Microsteps = 0 |
| 2) | Condition 1b) is fulfilled after a the SM module is reset or switched on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application. |
| 3) | The current range from approximately 1/3 of the nominal current up to the nominal current is used as operating range for determining the motor identifier. |

| Data type | Motor ID values | Explanation |
|-----------|-----------------|--|
| UINT | 0 | No motor identifier available (after switching on for as long as the measurement conditions are not met) |
| | 1 to 32767 | Valid range of values for the motor ID register (in µs) |
| | 65504 to 65519 | Ground fault: Measurement of motor identification not possible |
| | 65528 | Motor ID trigger not possible <ul style="list-style-type: none"> • Motor not supplied with current • Motor in movement • Nominal current set to 0 A • Ground fault present |
| | 65529 | Invalid value: Underflow |
| | 65530 | Overtemperature: Measurement not possible |
| | 65532 | Open circuit: Measurement not possible |
| | 65533 | Incorrect motor position: Measurement not possible |
| | 65534 | Invalid value: Overflow |
| | 65535 | Measurement in progress |

Ground fault detection

When the motor is powered on, a ground fault check is performed before motor identification. Error numbers have been added in the motor identification register for the event of a ground fault error (values 65504 to 65519 in the table above).

Error status

Name: The names of the bits are different depending on whether [SDC information](#) is enabled or disabled.

| Without SDC | With SDC |
|-------------------|---------------------|
| StallError | StallError01 |
| Overtemperature | Overtemperature01 |
| ErrorCurrentError | ErrorCurrentError01 |
| OvercurrentError | OvercurrentError01 |
| - | DrvOK01 |

The current error status of the drive is indicated in this register. Each bit indicates a certain error or status. If an error is registered in bits 0 to 3, then the corresponding bit remains set until the error has been acknowledged (see ["Module configuration 2"](#) on page 2626 and ["Error acknowledgment"](#) on page 2630).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|---|
| 0 | StallError(01) | 0 | No stall |
| | | 1 | Stall |
| 1 | Overtemperature error OvertemperatureError(01) | 0 | No overtemperature |
| | | 1 | Overtemperature |
| 2 | Current error CurrentError(01) | 0 | No current error |
| | | 1 | Current error |
| 3 | Overcurrent error OvercurrentError(01) | 0 | No overcurrent |
| | | 1 | Overcurrent |
| 4 | Status of the drive DrvOk0 ¹⁾ | 0 | An error was triggered for the motor axis |
| | | 1 | The drive is running error-free |
| 5 - 15 | Reserved | 0 | |

1) Only when SDC information is enabled

Overtemperature error

The "Overtemperature" error bit can be set for the following reasons:

- A specific temperature was exceeded near the channel due to overload
- Module temperature exceeds 85°C

Current error

This error bit occurs whenever the required current cannot be supplied to the motor windings. This can be (but is not necessarily) caused by an open line. At higher speeds (depending on the motor), this error can also occur without an open line. In this case it is simply no longer possible to supply the desired current to the motor windings. Because of the Back-EMF on the motor, this bit is set at slightly lower speeds if the motor is operated with no load compared with full or partial loads.

Overcurrent error

Overcurrent occurs if the motor current measured in the motor windings is twice as high as it should be (e.g. short circuit).

Status of the drive

The status of the drive is only shown when SDC information is enabled. The drive bit is 1 when the following conditions are met:

- Motor turned on (see ["Motor current"](#) on page 2629)
- Ground fault detection is completed and OK
- MotorID measurement is completed
- Motor is supplied with current
- Motor settling time has passed
- Supply voltage is in the valid range
- No overtemperature fault
- Preset position value is valid (see ["SDC life sign monitoring"](#) on page 2628)

9.25.7.13.7 Register description: Function model "Standard" without SDC information**9.25.7.13.7.1 Communication registers****Input counter state**

Name:

ModulePowerSupplyError

StatusInput01 to StatusInput04

This register is used to indicate the status of the digital inputs and counters.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|---|---|
| 0 | ModulePowerSupplyError | 0 | OK |
| | | 1 | Module supply error |
| 1 | Reserved | 0 | |
| 2 | StatusInput01 | When bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 1 |
| | | When bit 0 in Module configuration 1 = 1 | |
| | | x | Ref toggle bit for counter 1: The state of this bit is changed after the homing procedure is complete. |
| 3 | StatusInput02 | When bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 2 |
| | | When bit 0 in Module configuration 1 = 1 | |
| | | 0 | Homing of ABR counter active |
| | | 1 | Homing of ABR counter complete |
| 4 | StatusInput03 | 0 or 1 | Input state - Digital input 3 |
| 5 | StatusInput04 | 0 or 1 | Input state - Digital input 4 |
| 6 - 7 | Reserved | 0 | |

Motor StepX

Name:

MotorStep0 to MotorStep3

These registers specify the number and direction of steps that must be moved by the module during the next X2X cycle and also select the motor current (see also "[Holding current, rated current and maximum current](#)" on page 2617).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|---|-------|-------------------|
| 0 - 12 | Number of steps for the module to move during the next X2X cycle. | x | |
| 13 | Direction of movement | 0 | Positive |
| | | 1 | Negative |
| 14 - 15 | Selection of motor current | 00 | Motor not powered |
| | | 01 | Holding current |
| | | 10 | Nominal current |
| | | 11 | Maximum current |

Depending on the necessary resolution and maximum configurable speed, module configuration 1 can be used to set which bit position is used as the 1st position for full steps (see bits 5 and 6 of "[Module configuration 1](#)" on page 2619).

Example for 5-bit microsteps (set bits 5 and 6 of the module configuration to binary 00):

The number of transfer values per X2X cycle is specified by bits 3 and 4 in the module configuration 1 (see "[Module configuration 1](#)" on page 2619). If only one transfer value (bits 3 and 4 = 00) is specified, then the motor is advanced by MotorStep0 until the next X2X cycle. If 2 or 4 transfer values are specified, then the X2X cycle is divided accordingly.

Example: X2X cycle = 1 ms (1000 μ s)

| Time | Number of transfer values (see " Module configuration 1 " on page 2619) | | |
|--------------------|---|---------------------|---------------------|
| | 1 (bits 3 - 4 = 00) | 2 (bits 3 - 4 = 01) | 4 (bits 3 - 4 = 10) |
| 0 - 250 μ s | MotorStep0 | MotorStep0 | MotorStep0 |
| 250 - 500 μ s | | | MotorStep1 |
| 500 - 750 μ s | | MotorStep1 | MotorStep2 |
| 750 - 1000 μ s | | | MotorStep3 |

Position latched sync/async

Name:

PositionLatchedSync

PositionLatchedASync

The position counter (internal position counter or ABR counter) is applied at the latch event (see "Module configuration 2" on page 2626). Bits 3 and 7 of the "Counter configuration" on page 2618 register are used to determine which counter state (internal position counter or ABR encoder) should be saved in the registers "Position latched sync" and "Position latched async".

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

| Register | Counter configuration | |
|----------------|---------------------------|---------------------------|
| | Bit 3 ... 0 | Bit 3 ... 1 |
| Position sync | Internal position counter | ABR counter |
| Position async | ABR counter | Internal position counter |

Internal position counter

The internal position counter is the position calculated by the SM module (set position). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the register "Module configuration 1" on page 2619).

Example of the internal position counter format (7-bit micro steps, i.e. set bit 5 and 6 of the module configuration to binary 10):

ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

usSinceTrigger

Name:

usSinceTrigger

This register indicates the time (in μs) that has passed since the trigger event occurred (see "Module configuration 2" on page 2626).

Information:

The absolute accuracy of the trigger can be delayed up to 5 μs due to the input filter of the digital inputs.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Stepper latch trigger status

Name:
 LatchInput
 LatchDone
 TriggerInput

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|---|
| 0 | Latch input: | x | Digital input for the latch event (level) |
| 1 | LatchDone | x | Changes its state each time the counter state is successfully latched (reset value = 0) |
| 2 - 3 | Reserved | - | |
| 4 | TriggerInput | x | Trigger input (level) |
| 5 - 7 | Reserved | 0 | |

9.25.7.13.7.2 Configuration registers

Module configuration 2

Name:
 StartLatch
 TriggerEdgePos
 TriggerEdgeNeg
 StartTrigger
 TriggerEdge
 ClearError

The trigger functions for the stepper motor can be configured with this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|---|
| 0 | Latch function for stepper motor Latch byte | 0 | The latch function for stepper motor position is deactivated at the negative edge of this bit |
| | | 1 | The latch function for stepper motor position is deactivated at the positive edge of this bit |
| 1 - 2 | Latch mode for stepper motor TriggerEdgePos (Bit 1) TriggerEdgeNeg (Bit 2) | 00 | Latch position of stepper motor, unconditional |
| | | 01 | Latch position of stepper motor at positive edge on input DI 3 |
| | | 10 | Latch position of stepper motor at negative edge on input DI 3 |
| | | 11 | Reserved |
| 3 | TriggerEdge | 0 | Trigger edge (input DI 4) = positive |
| | | 1 | Trigger edge (input DI 4) = negative |
| 4 | Enable trigger (when changes occur) StartTrigger | x | |
| 5 | ClearError | 0 | No effect |
| | | 1 | Error acknowledgment for the motor (for more info, see "Error status" on page 2622) |
| 6 - 7 | Reserved | - | |

Trigger function procedure:

- Select the desired trigger edge using bit 3
- Enable the trigger function by changing the state of bit 4. When this bit changes, `usSinceTrigger` (μ s counter) is cleared.
- When the trigger event occurs, `usSinceTrigger` (μ s counter) is started.
- The `usSinceTrigger` counter cannot overrun, i.e. it is stopped at 2^{16} and retains this value until the next time the trigger function is activated.

The trigger function can be re-activated at any time by changing the state of bit 4, regardless of whether a trigger event has occurred or if `usSinceTrigger` has reached the maximum value.

Position sync 2

Name:

PositionSync02

Depending on [Counter configuration](#) (bit 3), this register contains the state of either the position counter or the ABR counter. It's an exact complement to the "Position sync" on [page 2620](#) register.

If the position sync register contains the position counter, then the PositionSync02 register contains the ABR counter state and vice versa.

By default, the register cannot be seen in the I/O map; instead, it has to first be activated in the I/O configuration.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.7.13.8 Register description: Function model "Standard" with SDC information

9.25.7.13.8.1 Configuration registers

SDC configuration

Name:

SDCConfig01

This register can be used to enable/disable additional SDC information.

The additional cyclic registers are hidden or shown depending on whether SDC information is disabled or enabled. It is comparable to the two variants of the standard function model [with](#) and [without SDC information](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|----------------------|
| 0 | Trigger edge | 0 | Rising trigger edge |
| | | 1 | Falling trigger edge |
| 1 - 5 | Reserved | 0 | |
| 6 | SDC life sign monitoring | 0 | Disabled |
| | | 1 | Enabled |
| 7 | SDC information ¹⁾ | 0 | Disabled |
| | | 1 | Enabled |

1) When the "SDC information" bit is enabled, the "EncOK01" bit is shown in the Automation Studio I/O mapping. This bit is linked to the ModulOK bit and always indicates its value.

Advice:

Neither SDC information nor SDC life sign monitoring is permitted to be changed at runtime.

Module configuration 1 with SDC

The "[Module configuration 1](#)" on [page 2619](#) register is ignored in the standard function model with SDC information enabled. The module behaves as if the module configuration were described as follows:

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 | Meaning of bits 2 and 3 in the register " Input counter value " on page 2629 | | |
| 1 - 2 | Reserved | 0 | |
| 3 - 4 | Number of transfer values per X2X cycle | 00 | 1x $\Delta s / \Delta t$ (transfer values: Motor settings Motor1Step0) |
| 5 - 6 | Resolution of microsteps | 11 | 8-bit microsteps |
| 7 - 15 | Reserved | 0 | |

Motor settling time

Name:

MotorSettlingTime01

This register determines the motor setting time. This is the minimum time from the time the motor is energized until the drive bit (DrvOK) is set (see "[Error status](#)" on page 2622). The setting is made in steps of 10 ms.

| Data type | Values | Information |
|-----------|----------|---------------------------------|
| USINT | 1 to 255 | 10 ms to 2.55 s, default: 10 ms |

Turn-off delay

Name:

DelayedCurrentSwitchOff01

If the [SDC life sign monitoring](#) is triggered (i.e. the [NetTime timestamp](#) is in the past) the motor is decelerated at nominal current with speed setpoint = 0.

Then the motor is switched off after the delay configured with this register.

| Data type | Value | Information |
|-----------|----------|---|
| USINT | 0 to 255 | 0 to 25.5 ms in steps of 100 ms (default: 100 ms) |

9.25.7.13.8.2 Communication registers**SDC life sign monitoring**

Name:

SetTime01

The module uses SDC life sign monitoring to check whether valid values have been received for the speed setpoint. SDC life sign monitoring is activated in the "[SDC configuration](#)" on page 2627 register by setting bit 6 (SDCSetTime = on).

If the specified [NetTime timestamp](#) is in the past, then an error is triggered for the motor axis (only when the motor is switched on). The module performs the following steps:

- 1) The CPU is informed of the error using the Drive bit (DrvOk) = 0
- 2) Braking at configured rated current with speed setpoint = 0
- 3) Wait for configured turn-off delay to expire
- 4) Power off motor

When the timestamp is back in the valid range, the motor can be powered on again by a rising edge on the DriveEnable bit (see "[Motor current](#)" on page 2629).

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Motor current

Name:

DriveEnable01

BoostCurrent01

StandstillCurrent01

Bits 0 to 2 of this register control the motor's current feed.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------------|-------|-----------------|
| 0 | DriveEnable01 | x | Motor powered |
| 1 | BoostCurrent01 | x | Maximum current |
| 2 | StandstillCurrent01 | x | Holding current |
| 3 - 7 | Reserved | 0 | |

The possible status of bits 0 to 2

| StandstillCurrent01 | BoostCurrent01 | DriveEnable01 | Description |
|---------------------|----------------|---------------|-----------------------------------|
| x | x | 0 | Motor not supplied with current |
| 0 | 0 | 1 | Rated current supplied to motor |
| 0 | 1 | 1 | Maximum current supplied to motor |
| 1 | 0 | 1 | Holding current supplied to motor |
| 1 | 1 | 1 | Holding current supplied to motor |

Lifecycle counter

Name:

LifeCnt

This register is incremented by one with each X2X Link cycle.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Input counter value

Name:

ModulePowerSupplyError

StatusInput01 to StatusInput04

This register contains the state of the digital inputs and counter.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|--------|-------------------------------|
| 0 | ModulePowerSupplyError | 0 | OK |
| | | 1 | Error in module power supply |
| 1 | Reserved | 0 | |
| 2 | StatusInput01 | 0 or 1 | Input state - Digital input 1 |
| ... | | ... | |
| 5 | StatusInput04 | 0 or 1 | Input state - Digital input 4 |
| 6 - 7 | Reserved | 0 | |

Error acknowledgment

Name:
ClearError01

This register can be used to acknowledge errors that have occurred on the motor.

For more info, see ["Error status" on page 2622](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|--------------------------------|
| 0 - 4 | Reserved | 0 | |
| 5 | ClearError01 | 0 | No effect |
| | | 1 | Error acknowledgment for motor |
| 6 - 7 | Reserved | 0 | |

Motor1Step0

Name:
Motor1Step0

This registers is used to specify the number and direction of steps that should be carried out by the module during the next X2X cycle.

The value is specified with a resolution of 1/256 of a full step (corresponds to 8-bit microsteps).

The direction of movement is derived from the value's sign:

| Data type | Values | Information |
|-----------|--------|--|
| INT | >0 | Movement in the positive direction in 1/256 full steps |
| | <0 | Movement in the negative direction in 1/256 full steps |

Unlike function model "Standard" without enabled SDC information, the motor current is selected using a separate register (see register ["Motor current" on page 2629](#)).

Home position

Name:
RefPulsePos01

These 2 registers have the following contents:

| Register | Description |
|--|--|
| Home position of the internal position counter | This register contains the home position of the internal position counter. |
| Home position for the ABR counter | This register contains the home position of the ABR counter. |

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Setting "Position sync" in the Automation Studio I/O configuration can be used to select which of the 2 registers is addressed by variable RefPulsePos01.

| Variables in Automation Studio | I/O configuration, counter 01, option "Position sync" | |
|---|---|---|
| | Stepper counter 01 is indicated on ActPos01 . | ABR counter 01 is indicated on ActPos01 . |
| RefPulsePos01 | Home position of the internal position counter | Home position of the ABR counter |
| Option "Position sync" for counter 1 also sets bit 3 in register "Counter configuration" on page 2618 : | | |
| Bit 3 (counter 1) | 0 | 1 |

Reference pulse counter

Name:

RefPulseCnt01

These 2 registers have the following contents:

| Register | Description |
|---|---|
| Reference pulse counter for the internal position counter | The reference pulses of the internal position counter are counted in this register. |
| Reference pulse counter for the ABR counter | The reference pulses of the ABR counter are counted in this register. |

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Setting "Position sync" in the Automation Studio I/O configuration can be used to select which of 2 registers is addressed by variable RefPulsePos01.

| Variables in Automation Studio | I/O configuration, counter 01, option "Position sync" | |
|--|---|---|
| | Stepper counter 01 is indicated on ActPos01 . | ABR counter 01 is indicated on ActPos01 . |
| RefPulseCnt01 | Reference pulse counter for the internal position counter | Reference pulse counter of the ABR counter |
| Option "Position sync" for counter 1 also sets bit 3 in register "Counter configuration" on page 2618: | | |
| Bit 3 (counter 1) | 0 | 1 |

NetTime of the position value

Name:

ActTime01

This register contains the NetTime of the most recent valid position value.

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Trigger counter

Name:

TriggerCnt01

This register contains a cyclic counter that is incremented with each trigger event.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Trigger timestamp

Name:

TriggerTime01

This register contains the NetTime instant of the most recent trigger event. The trigger edge must be configured in register ["SDC configuration" on page 2627](#).

For more information about NetTime and timestamps, see ["NetTime Technology" on page 3035](#).

Information:

The absolute accuracy of the trigger can be delayed up to 5 μ s due to the input filter of the digital inputs.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.7.13.9 Register description: Function model 254 - "Bus controller" and function model 3 - "Ramp"**9.25.7.13.9.1 Configuration registers****Holding current, rated current and maximum current**

Name:

ConfigOutput03a (holding current)

ConfigOutput04a (rated current)

ConfigOutput05a (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

| Register | Description |
|-----------------|--|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases. In the mode "Homing during stall", the rated current is always used instead of the maximum current, even in acceleration phases. |
| Holding current | Current when motor is at standstill |

When the current changes to a weaker value (e.g. when transitioning from the acceleration phase to the constant speed mode), the stronger current is maintained for an additional 100 ms. This is done according to the following priority regardless of the actual defined values: maximum current before nominal current before holding current.

| Data type | Value | Unit |
|-----------|----------|--|
| USINT | 0 to 117 | Percent of the module's rated current <ul style="list-style-type: none"> • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 117% corresponds to the maximum current of the motor bridge power unit listed in the technical data Bus controller default setting: 0 |

Full step threshold

Name:

FullStepThreshold01

This register defines the threshold speed, above which the motor is operated in full step mode, and below which it is operated in microstep mode.

| Data type | Value | Information |
|-----------|------------|---|
| UINT | 1 to 65534 | Speed in microsteps / cycle. Bus controller default setting: 0 |
| | 65535 | Motor is always operated in microstep mode |

Maximum speed

Name:

MaxSpeed01pos

This register defines the maximum speed for the absolute positioning modes (1, -123, -124, -125, -126).

Information:

The setting does not apply to the speed and homing modes (2, -127, -128).

| Data type | Value | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Speed in microsteps / cycle. Bus controller default setting: 0 |

Maximum acceleration

Name:

MaxAcc01

This register defines the maximum acceleration (also applies for homing modes).

| Data type | Value | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Acceleration in microsteps / cycle ² . Bus controller default setting: 0 |

Maximum deceleration

Name:
MaxDec01

This register defines the maximum deceleration (also applies for homing modes).

| Data type | Value | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Deceleration in microsteps / cycle ² . Bus controller default setting: 0 |

Reversing loop

Name:
RevLoop01

This parameter is only used in mode 1, -123, -124, -125, -126 (absolute positioning modes).

If the value for the reversing loop is not equal to 0, the target position is approached directly when coming from one direction; when coming from the other direction, the target position is initially overshoot by the configured number of steps before finally moving to the target position. This ensures that the target position is always approached from the same direction (to avoid mechanical backlash).

The sign of the defined value determines the direction in which the reversing loop runs.

| Sign | Effective direction |
|----------|--|
| Positive | Reversing loop in positive direction of movement |
| Negative | Reversing loop in negative direction of movement |

| Data type | Values | Information |
|-----------|-----------------|-----------------------------------|
| INT | -32768 to 32767 | Bus controller default setting: 0 |

Fixed position A

Name:
FixedPos01a

This register defines the position to move to in modes -124 (if the digital input is set to 1) and -125.

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Fixed position B

Name:
FixedPos01b

This register defines the position to move to in modes -124 (if the digital input is set to 0) and -126.

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Homing speed

Name:
RefSpeed01

This register sets the speed for homing modes -127 and -128.

| Data type | Value | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Speed in microsteps / cycle. Bus controller default setting: 0 |

Stall recognition delay

Name:

StallRecognitionDelay01

The value in this register is only relevant for "Homing during stall".

A stall is only detected after the time specified here has expired and after the homing procedure has started.

For example, a setting of 4 (and a cycle time of 25 ms) means that a stall will not be detected until 100 ms after the motor starts moving (start of the homing procedure).

Set to 0 to eliminate delay.

| Data type | Value | Information |
|-----------|----------|---|
| USINT | 0 to 255 | in cycles, see "General configuration" on page 2636. Bus controller default setting: 0 |

Minimum speed for stall detection

Name:

StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled and the configured **mixed decay threshold** is used. The value 15 is always used for the mixed decay threshold below this threshold value, and no stall error is reported. This means that mixed decay mode is always enabled at low speeds where stall detection principally does not work.

| Data type | Value | Information |
|-----------|------------|---|
| UINT | 0 to 65535 | Minimum speed in microsteps per cycle. Bus controller default setting: 0 |

Jolt time

Name:

JoltTime01

If a value other than 0 is assigned to this register, then jolt limitation is performed. This is done by averaging the values for the steps to be carried out (speed setpoint) in each cycle using FIFO memory. The jolt time corresponds to the number of FIFO elements (0 to 80). If a value greater than 80 is entered, then it will be limited internally to 80.

Changes made while a motor is running will be applied as soon as ...

- the motor has reached the position setpoint (positioning modes only)
- the motor has stopped (all modes)

| Data type | Value | Information |
|-----------|-----------------------|---|
| USINT | 0 | No jolt time limitation. Bus controller default setting: 0 |
| | 1 to 80 ¹⁾ | Number of FIFO elements |

1) Starting with upgrade 1.4.1.0 (firmware version 14); For older versions: 16

Homing configuration

Name:

RefConfig01

The homing mode can be set with this register.

| Data type | Values | Information |
|-----------|------------|--|
| SINT | -120 | Set home position |
| | -121 | Homing on positive edge of input DI 4 |
| | -122 | Homing on falling edge of input DI 4 |
| | -125 | Homing on positive edge of input DI 3 (R pulse). Bus controller default setting |
| | -126 | Homing on negative edge of input DI 3 (R pulse) |
| | -127 | Homing during stall detection |
| | -128 | Immediate homing |
| | All others | No effect |

Stall detection configuration / Mixed decay

Name:

StallDetectConfig01

The mixed decay threshold and stall detection sensitivity can be configured in this register.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------|---------|---|
| 0 - 3 | Mixed decay threshold | 0 | Mixed decay disabled (bus controller default setting) |
| | | 1 to 14 | Setting for mixed decay threshold |
| | | 15 | Mixed decay always enabled |
| 4 - 6 | Stall threshold | 0 | Stall detection is disabled (bus controller default setting) |
| | | 1 to 6 | Steps involved in setting stall detection sensitivity |
| | | 7 | Maximum sensitivity for stall detection |
| 7 | Motor load | 0 | Motor load value not shown (bus controller default setting) |
| | | 1 | Show value in register "Status word" on page 2644 ¹⁾ |

1) If this bit is 1, then the motor load value is indicated in bits 13 to 15 of the status word register (otherwise these bits are 0). This value can help when testing stall detection and *Home during stall mode*.

Stall threshold

The SM module features integrated sensorless load measurement for the motor axis. This is especially useful for detecting a "stall condition" (e.g. if the motor moves to the end point during a homing procedure). It cannot be used for torque monitoring during dynamic movements.

The "stall threshold" (bits 4 to 6 of this register) can be used to define a threshold value for each axis individually according to the motor load, beyond which the motor will detect a stall condition.

This threshold value must be determined on a case-by-case basis, since the results of load measurement are influenced by a variety of factors.

- Motor speed: A higher speed results in higher measurement values
- Speeds that cause motor resonances (which interfere with load measurement) are to be avoided
- Motor accelerations that create a dynamic load (and also affect the measurement) should also be avoided
- It is especially important to be aware that mixed decay mode must be optimized for reliable stall detection.

The higher the load measurement value, the lower the load. This means that a stall condition is detected if the load measurement value drops below the trigger threshold for stall detection.

Mixed decay threshold

Mixed decay modules provide a greatly optimized sinusoidal current profile in the individual phases of the stepper motor, especially for fast current changes and low current values.

Mixed decay interferes with reliable stall detection, however. For this reason, mixed decay mode can be disabled during stall detection (motor load measurement) using the mixed decay threshold. The smaller the configured mixed decay threshold, the larger the range in which mixed decay is disabled while motor load measurement takes place.

Mixed decay mode is always enabled if the mixed decay threshold is set to 15.

Relationship between stall detection and mixed decay

Depending on the application and the motor used, satisfactorily smooth operation can be achieved while using stall detection by setting the mixed decay threshold to a value between 1 and 14. This is a compromise between smooth operation and stall detection quality and must be fine tuned during commissioning.

General configuration

Name:

GeneralConfig01

Bit 0 of this register can be used to switch the positioning mode. This register can also be used to configure the cycle time of the motion profile generator.

- 0: "Mode 1: Position mode" without extended control word
- 1: "Mode 1: Position mode with extended control word"

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|--|
| 0 | Position mode | 0 | Without extended control word (bus controller default setting) |
| | | 1 | With extended control word |
| 1 - 2 | Cycle time of the motion profile generator ¹⁾ | 00 | 25 ms (bus controller default setting) |
| | | 01 | 10 ms |
| | | 10 | 5 ms |
| | | 11 | Reserved |
| 3 - 7 | Reserved | 0 | |

1) This parameter is supported starting with upgrade 1.4.1.0 (firmware version 14).

The cycle time for the motion profile generator is configured with this cycle. This cycle time affects the unit for specifying the speed and acceleration:

- Unit for speed: Microsteps/Cycle
- Unit for acceleration: Microsteps/Cycle²

Limit switch configuration

Name:

LimitSwitchConfig01

This register configures the behavior of the limit switches.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------|-------|---|
| 0 - 1 | Negative limit switch | 00 | Switched off (bus controller default setting) |
| | | 01 | Active if low |
| | | 10 | Reserved |
| | | 11 | Active if high |
| 2 - 3 | Positive limit switch | 00 | Switched off (bus controller default setting) |
| | | 01 | Active if low |
| | | 10 | Reserved |
| | | 11 | Active if high |
| 4 - 6 | Reserved | 0 | |
| 7 | Direction monitoring | 0 | Off (bus controller default setting) |
| | | 1 | On |

Negative/Positive limit switch:

When one of the limit switches is reached, a warning is triggered and the speed is decelerated to 0. There is no state change of "Device control state machine". This keeps current flowing to the motor.

The error that occurred can be read from the error code register. Normal operation can be resumed by acknowledging the warning. This will not restrict motor movement to a specific direction and the limit switch will not be triggered until the next active edge.

Overshooting the limit switch while braking

The limit switches are not linked with the corresponding direction of movement. If the limit switch is exceeded, another error will be triggered when reversing after acknowledging the initial error.

Direction monitoring

If this function is enabled, then the two limit switches will be linked with the respective direction of movement. This means that the negative limit switch is only triggered in the negative and the positive limit switch only in the positive direction of movement (specified direction).

This prevents specifying a movement in the wrong direction when direction monitoring is enabled and limit switches are active.

Warning!

If the motor is wired incorrectly with this configuration (wrong direction of movement), then the limit switch will not be triggered and the actual correct direction of movement will be denied. This will also be the case when the limit switch connections are reversed.

Software limit

Name:

PositionLimitMin01

PositionLimitMax01

This register configures software limits. The function is active if at least one of the two registers is unequal to zero. These limits are effective in all positioning modes. Position overrun is not possible when this function is enabled. Movement is always contained within the two limits.

If a position is specified that violates the minimum/maximum software limit, the "Internal limit active" bit will be set in the "Status word" on page 2644 register. The motor movement will be stopped until a position is specified within the limits.

The "Internal limit active" bit will also be set in the "Status word" register if there is a configuration error (minimum > maximum).

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Information:

The software limits will only be monitored in connection with the following CANopen bus controllers:

- X20BC0043-10
- X20BC0143-10
- X67BC4321-10
- X67BC4321.L08-10
- X67BC4321.L12-10

9.25.7.13.9.2 Reading back the configuration

Reading back the holding current, nominal current and maximum current

ConfigOutput03aRead (holding current)

ConfigOutput04aRead (nominal current)

ConfigOutput05aRead (maximum current)

These registers are used to read the respective current values in percent.

| Register | Description |
|-----------------|--|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases |
| Holding current | Current when motor is at standstill |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 255 | Percentage of module's nominal current (100% corresponds to the nominal current of the motor bridge power unit in the technical data) |

9.25.7.13.9.3 Communication registers

Set position/speed

Name:

AbsPos01

This register is used to set position or speed, depending on the operating mode.

- Position mode (see "Mode" on page 2639): Cyclic setting of the position setpoint in microsteps. In this mode, one micro-step is always 1/256 full-step.
- Speed mode (see "Mode" on page 2639): In this mode, this register is considered a signed speed setpoint.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Control word

Name:

MpGenControl01

This register can be used to issue commands based on the module's state (see ["Ramp function model operation on page 2648"](#)).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|------------------------|-------|--|
| 0 | Switch on | x | |
| 1 | Enable voltage | x | |
| 2 | Quick stop | x | |
| 3 | Enable operation | x | |
| 4 - 6 | Mode-specific | x | |
| 7 | Fault reset | x | |
| 8 | Stop ¹⁾ | x | |
| 9 - 10 | Reserved | 0 | |
| 11 | Motor ID trigger | 0 | No effect |
| | | 1 | Rising edge: Motor ID trigger ²⁾ |
| 12 | Warning reset | 0 | No effect |
| | | 1 | Rising edge: Reset warnings |
| 13 | Undercurrent detection | 0 | Disable current error detection (default) |
| | | 1 | Enable current error detection |
| 14 | ABR counter sync/async | 0 | Default: <ul style="list-style-type: none"> Internal position counter, cyclic ABR counter, acyclic |
| | | 1 | <ul style="list-style-type: none"> Internal position counter, acyclic ABR counter, cyclic |
| 15 | Stall detection | 0 | Disable stall detection (default) |
| | | 1 | Enable stall detection |

1) The "Halt" bit is only evaluated when the extended control word is enabled (see ["General configuration" on page 2636](#)).

2) This bit can be used to trigger a measurement of the motor ID. Keep in mind that the application must ensure that the conditions for measurement are fulfilled (see table in the ["Motor identification" on page 2645](#) register).

Mode

Name:

MpGenMode01

| Data type | Value | Information |
|-----------|-------|--|
| SINT | 0 | No mode selected |
| | 1 | Depending on bit 0 in the "General configuration" on page 2636 register, the position mode will behave as follows: <ul style="list-style-type: none"> Position mode without extended control word: Move to target position as soon as the target position changes Position mode with extended control word: Move to position setpoint as described in "Mode 1 - Position mode with extended control word" on page 2640 |
| | 2 | Speed mode: Constant speed |
| | -120 | Set reference position |
| | -121 | Remaining distance mode |
| | -122 | Set actual position |
| | -123 | Move to target position when external input set |
| | -124 | Two-position module |
| | -125 | Move to fixed position A (position set acyclically) |
| | -126 | Move to fixed position B (position set acyclically) |
| | -127 | Positive homing (see also "Homing configuration" on page 2634) |
| | -128 | Negative homing (see also "Homing configuration" on page 2634) |

Information:

For all modes: The "Target reached" bit is set in the ["Status word" on page 2644](#) register when the current action is finished (i.e. when the position or speed is reached, depending on the mode).

A new position or speed can be specified even before the current action is finished.

Mode 1 - Position mode

The position setpoint is specified in the "Set position/speed" on page 2638 register. The motor is then moved to this new position. This is done with a ramp function that accounts for the defined maximum speed and acceleration values.

The position setpoint can also be changed during an active positioning procedure.

The position setpoint is specified in microsteps (1/256 of a full step).

If bit 0 in the "General configuration" on page 2636 register is 0 (no extended control word), then the position setpoint will be applied as soon as it is different from the current position. Then the new position is used for the movement.

However, if bit 0 in the "General configuration" on page 2636 register is set to 1 (extended control word), then the position setpoint will be applied as described under "Mode 1 - Position mode with extended control word" on page 2640.

Mode 1 - Position mode with extended control word

The position mode with extended control word behaves like the previously described Position mode 1 (without extended control word) except that the new position setpoint ("Position/speed" on page 2638 register) is applied according to the extended control word.

Extended control word

This register can be used to issue commands based on the module's state (see "Ramp function model operation" on page 2648).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|---|
| 0 - 3 | Corresponds to the default Control word | x | |
| 4 | New setpoint | 0 | Do not apply position setpoint |
| | | 1 | Apply position setpoint |
| 5 | Change set immediately | 0 | Complete current positioning movement and then start next positioning movement |
| | | 1 | Interrupt current positioning movement and then start next positioning movement |
| 6 | abs / rel | 0 | Position setpoint is an absolute value |
| | | 1 | Position setpoint is a relative value |
| 7 | Corresponds to the default Control word | x | |
| 8 | stop ¹⁾ | 0 | Execute positioning |
| | | 1 | Stop axis with deceleration |
| 9 - 15 | Corresponds to the default Control word | x | |

1) This bit applies to all modes.

Extended status word

The bits in the status word reflect the status of the state machine (for a detailed description, see "Status word" on page 2649 and "State machine" on page 2650).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|---|-------|---|
| 0 - 9 | Corresponds to the default Status word | x | |
| 10 | Target reached, depending on bit 8 (Halt) in the register "Control word" on page 2639 | | If Halt = 0 |
| | | 0 | Position setpoint not reached |
| | | 1 | Position setpoint reached |
| | | | If Halt = 1 |
| | | 0 | Axis decelerating |
| 11 | Corresponds to the default Status word | 0 | Axis speed = 0 |
| | | 1 | |
| 12 | Setpoint acknowledge | 0 | Ramp generator did not apply the position value |
| | | 1 | Ramp generator applied the position value |
| 13 - 15 | Corresponds to the default Status word | x | |

Position setting

The target position can be defined in 2 different ways:

| Type of setpoint definition | Description |
|-----------------------------|--|
| Single setpoint | After the target position is reached, Bit <i>Target reached</i> in register "Status word" on page 2644 is set. A new target position (setpoint) is then defined. The drive stops at each target position before starting the movement to the next target position. |
| Set of setpoints | After the target position has been reached, the movement to the next target position is started immediately without stopping the drive. It is therefore possible to initiate a new positioning by specifying another target position during active positioning. |

Table 510: Types of position setpoint definition

The two options "Single setpoint" and "Set of setpoints" are controlled by the timing of bits *New setpoint* and *Change set immediately* in the "extended control word" on page 2640 and *Setpoint acknowledge* in the "extended status word" on page 2640 register.

These bits can be used to create a Request-Response mechanism. This makes it possible to specify a target position while a previous position specification is still being processed.

Specifying the target position

Figure 177: Principle for applying the setpoint

Transferring a new setpoint:

- 1) If bit *Setpoint acknowledge* in register "Extended status word" on page 2640 is 0, the module will accept a new target position.
- 2) The new target position is specified in register "Set position/speed" on page 2638.
- 3) A rising edge on bit *New setpoint* in the "extended control word" on page 2640 indicates that the new target position in register "Set position/speed" on page 2638 is valid and can be used for the next positioning movement.
- 4) After the module has received and saved the new target position, bit *Setpoint acknowledge* is set to 1 in register *Status word*.
- 5) Now the controller can reset the *New setpoint* bit to 0.
- 6) Then the module resets bit *Setpoint acknowledge* to 0 to signal when a new target position is accepted.

Position specification "Single setpoint"

If bit *Change set immediately* is set to 0 (Ⓐ in figure "Principle for applying the setpoint"), then the module is operating with position specification *Single setpoint*. This mechanism results in a speed of 0 when the motor reaches target position x_1 at time t_1 . After the controller has been notified that the setpoint has been reached, the next target position x_2 will be processed at time t_2 and reached at t_3 .

Figure 178: Ramp in *Single setpoint*

Position specification "Set of setpoints"

If bit *Change set immediately* is set to 1 (Ⓢ in figure "Principle for applying the setpoint"), then the module is operating with position specification *Set of setpoints*. This means that the module receives the first target position at t_0 . A second target position is received at time t_1 . The drive immediately adapts the current movement to the new target position.

Figure 179: Ramp in *Set of setpoints*

Relative position setting

When the *abs / rel* bit in the "Extended control word" on page 2640 register is set, then the position setpoint is interpreted as a relative value. At each *New setpoint* trigger, the position setpoint will be increased by this value (or decreased if the value is negative).

If the mode changes between the position settings, relative movement will then proceed starting at the last specified position. The position setpoint mode is initialized with 0 when the module is started.

Mode 2: Speed mode - Constant speed (pos./neg.)

The value in the "Position/Speed" on page 2638 register is now interpreted as the speed setpoint (microsteps/cycle).

Observing the maximum permissible acceleration, the motor moves with a ramp to the desired speed setpoint and maintains this speed until a new speed setpoint is specified.

Values are allowed within the range -65535 to 65535. When a value is entered outside of this range, it is readjusted to these limits.

Mode -120: Set home position

This mode is supported starting with upgrade 1.4.1.0 (firmware version 14).

The current value for the actual position is modified so that the position specified by the "Position/Speed" on page 2638 register is the home position. If you subsequently move to this position, the motor is at the home position.

The home position in the "Home position" on page 2646 register is also set to this value.

Before this mode is called, the motor must be at a standstill and the home position must have been determined using "Positive / negative homing" mode. In order to set the position, the *State machine* must be in state "Operation enable".

Mode -121: Remaining distance mode (like Modus 1)

The number of steps defined in the "Fixed position A" on page 2633 register are added to the current position and the resulting position is approached at a rising/falling edge on digital input 3.

Advice:

Steps are not added to the position setpoint, but rather to the current position at the moment the trigger occurs.

Negative values are also allowed for the offset defined in Fixed position A.

New position setpoints are no longer accepted in the "Position/speed" on page 2638 register after the trigger event. There must first be a switch made to mode 0 and then back to mode -121.

The "Target reached" bit in the "Status word" on page 2644 register is not set to 1 until the end position (after the trigger event) has been reached.

The "homing configuration" on page 2634 determines whether a rising or falling edge of the digital input is used as a trigger.

The Reversing loop is not enabled in this mode (i.e. any configured values not equal to 0 are ignored).

Mode -122: Set the actual position

The position setpoint set in the "Position/speed" on page 2638 register is accepted as the current actual position in the internal position counter when the state machine is in the "Operation Enable" state.

Before this mode is started, the motor must be at a standstill and physically located at the point for which the position being set should be applied.

Mode -123: Move to the position setpoint when the external input is set

The set position defined in the "Position/speed" on page 2638 is moved to when a rising edge occurs on the corresponding digital input.

A new position setpoint is not accepted until another rising edge occurs on the corresponding digital input. This can also occur during the active positioning procedure and will be applied immediately.

Mode -124: Two-position mode

Positions Fixed position A and Fixed position B are defined in the acyclic registers.

Value 1 on digital input 3 moves to fixed position A. Value 0 moves to fixed position B. It is also possible to switch between the two during an active positioning movement.

Mode -125/-126: Move to fixed position X

The purpose of these modes is to enable a virtual switch from speed mode to position mode, which otherwise is not possible because of the shared use of the register for position and speed setpoints.

- Mode -125: "Fixed position A" on page 2633
- Mode -126: "Fixed position B" on page 2633

Mode -127/-128: Homing (positive/negative)

Mode -127 and -128 are used to select which direction to move in.

The motor must be at a standstill before switching from another mode to one of the homing modes.

If the homing condition occurs, then the motor stops and the values of the position counter and ABR counter valid at the moment when the homing condition occurs are written to the "Homed zero position" on page 2646 register.

You must specify in the Homing configuration whether homing should occur at low/high level on the digital input, during stall or unconditionally.

Homing via digital input

Case 1: Active homing level not yet reached → Motor not yet at end position:

Movement continues at homing speed in the homing direction until the active level for "homing-stop" is on the digital input.

Case 2: Active homing level already reached → Motor at end position:

Movement continues at the homing speed, counter to the homing direction, until the active level for "homing-stop" is no longer on the digital input. Movement continues at homing speed in the homing direction until the active level for "homing-stop" is on the digital input again.

Homing during stall

Movement continues in the homing direction until a stall is detected. When a stall is detected, the value of the position counter is entered in the "[Homed zero position](#)" on [page 2646](#) register within one millisecond. The motor is then stopped abruptly (not using the deceleration ramp). However, it can take up to 25 ms to stop the motor because the ramp generator runs with a configurable internal cycle of up to 25 ms.

In this mode, the rated current is always used instead of the maximum current, even in acceleration phases.

To test the response behavior of this homing mode, the motor load value used for identifying a stall can be made visible in the status word (see "[Stall detection configuration / Mixed decay](#)" on [page 2635](#)).

Homing unconditional (immediate)

Immediate homing: The current values of the position counter and ABR counter are immediately entered in the "[Homed zero position](#)" on [page 2646](#) register (no motor movement).

Current position (cyclic)

Name:

AbsPos01ActVal

This cyclic register contains the current position.

Default: Value of the internal position counter, can be changed to ABR counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Status word

Name:

MpGenStatus01

The bits in this register reflect the state of the state machine. For a more detailed description, see "[Status word](#)" on [page 2649](#) and "[State machine](#)" on [page 2650](#).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|-----------------------------|-------|---|
| 0 | Ready to switch on | x | |
| 1 | Switched on | x | |
| 2 | Operation enabled | x | |
| 3 | Fault (error bit) | x | |
| 4 | Voltage enabled | x | |
| 5 | Quick stop | x | |
| 6 | Switch on disabled | x | |
| 7 | Warning | x | |
| 8 | Reserved | 0 | |
| 9 | Remote | 1 | Always 1 because there is no local mode for the SM module |
| 10 | Target reached | x | |
| 11 | Internal limit active | 0 | No limit violation |
| | | 1 | Internal limit is active (upper/lower software limit violated) |
| 12 | Mode-specific | x | |
| 13 - 15 | Reserved / Motor load value | 0 | Always 0 when bit 7 in the " Stall detection configuration / Mixed decay " on page 2635 register is set to 0. |
| | | x | Returned motor load value |

Input status

Name:

InputStatus

This register indicates the logical states of digital inputs.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|--------|-------------------------------|
| 0 | Digital input 1 | 0 or 1 | Input state - Digital input 1 |
| ... | | ... | |
| 3 | Digital input 4 | 0 or 1 | Input state - Digital input 4 |
| 4 - 7 | Reserved | 0 | |

Motor identification

Name:

Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. After successful measurement, this register contains the time [µs] required to apply a current increase of $\Delta I = 1$ A to a motor winding.

This depends on:

- Operating voltage
- Inductance and resistance of the motor winding

| Notes | |
|-------|---|
| 1) | To achieve reproducible results, the measurement must be made under the following defined conditions: |
| a) | Motor is at standstill. |
| b) | The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: <ul style="list-style-type: none"> • Full steps are divisible by 4. • Microsteps = 0 |
| 2) | Condition 1b) is fulfilled after a the SM module is reset or switched on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application. |
| 3) | The current range from approximately 1/3 of the nominal current up to the nominal current is used as operating range for determining the motor identifier. |

| Data type | Motor ID values | Explanation |
|-----------|-----------------|--|
| UINT | 0 | No motor identifier available (after switching on for as long as the measurement conditions are not met) |
| | 1 to 32767 | Valid range of values for the motor ID register (in µs) |
| | 65504 to 65519 | Ground fault: Measurement of motor identification not possible |
| | 65528 | Motor ID trigger not possible <ul style="list-style-type: none"> • Motor not supplied with current • Motor in movement • Nominal current set to 0 A • Ground fault present |
| | 65529 | Invalid value: Underflow |
| | 65530 | Overtemperature: Measurement not possible |
| | 65532 | Open circuit: Measurement not possible |
| | 65533 | Incorrect motor position: Measurement not possible |
| | 65534 | Invalid value: Overflow |
| | 65535 | Measurement in progress |

Ground fault detection

When the motor is powered on, a ground fault check is performed before motor identification. Error numbers have been added in the motor identification register for the event of a ground fault error (values 65504 to 65519 in the table above).

Homed zero position

Name:

RefPos01CyclicCounter

RefPos01AcyclicCounter

After a homing procedure, the homing point for the cyclic or acyclic position counter can be read back with these registers (either the internal position counter or ABR counter depending on bit 14 of register "Control word" on [page 2639](#)).

The following two registers are provided for the motor:

- Homed zero position for cyclic counter
- Homed zero position for acyclic counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Current position (acyclic)

Name:

AbsPos1ActValAcyclic

This acyclic register contains the current position.

Default: Value of the ABR counter, can be changed to internal position counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Reading back the control word

Name:

ControlReadback01

With this register, the contents of register "Control word" on [page 2639](#) can be read back.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Read back mode

Name:

ModeReadback01

This register can be used to read the content of the "Mode" on [page 2639](#) register.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Error code

Name:

ErrorCode01

The cause of an error or warning can be read in this register.

| Data type | Error code | Error type | Priority | Description |
|-----------|------------|------------|----------|-----------------------------|
| UINT | 0x0000 | - | - | No error |
| | 0x3000 | Error | hoch | Voltage |
| | 0x4200 | Error | : | Overtemperature |
| | 0xFF20 | Warning | : | Negative limit switch |
| | 0xFF21 | Warning | : | Positive limit switch |
| | 0x2300 | Warning | : | Overcurrent |
| | 0xFF00 | Warning | : | Current error ¹⁾ |
| | 0xFF01 | Warning | Low | Stall ²⁾ |

1) A current error is only detected if bit 13 = 1 in the [control word](#) (current error detection enabled).

2) Stall is only detected if bit 15 = 1 in the [control word](#) (stall detection enabled).

Information regarding the handling of errors and warnings:

- Bit 3 (Fault) and bit 7 (Warning) in the [status word](#) can be used to query whether an error or a warning was reported in the Error code register.
- Bit 7 (Fault Reset) and bit 12 (Warning Reset) in the [control word](#) are used to acknowledge pending errors and warnings.
- If two or more errors/warnings are pending, the one with the highest priority (the order in the table above) will be displayed in the Error code register.

9.25.7.13.9.4 Ramp function model operation

Control for this model has been based on the CANopen communication profile DS402.

Commands for controlling the modules are written to the "Control word" on page 2648. The current module state is returned to the "Status word" on page 2649 register. The function mode (absolute position, constant speed, homing, etc.) is set in the "Mode" on page 2639 register.

Control word

Control word bits and their state for the commands of the state machine:

| Command | Reserved | Encoder position sync/async | Current error detection | Warning reset | Motor ID trigger | Reserved | Reserved | Stop 2) | Fault reset | Mode-specific | Mode-specific | Mode-specific | Enable operation | Quick stop | Enable voltage | Switch on |
|-------------------|----------|-----------------------------|-------------------------|---------------|------------------|----------|----------|---------|-------------|---------------|---------------|---------------|------------------|------------|----------------|-----------|
| Bit ¹⁾ | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Shutdown | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 1 | 1 | 0 |
| Switch on | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | 0 | 1 | 1 | 1 |
| Disable voltage | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | x | 0 | x |
| Quick stop | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 0 | 1 | x |
| Disable operation | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | 0 | 1 | 1 | 1 |
| Enable operation | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | 1 | 1 | 1 | 1 |
| Fault reset | x | x | x | x | x | 0 | 0 | x | ↑ | x | x | x | x | x | x | x |

1) x ... Any; ↑ ... Rising edge

2) Bit 8 (stop) is only evaluated if the extended control word is enabled in register "General configuration" on page 2636.

| | |
|---|--|
| Bits 0, 1, 2, 3 and 7 (light gray in the previous table) | These bits control the state of the State machine according to the commands in the table above. |
| Stop | 0 ... Perform motor movement 1 ... Stop axis with deceleration This bit is only evaluated when the extended control word is activated in the "General configuration" on page 2636 register. |
| Motor ID trigger | A rising edge enables the motor ID measurement. |
| Warning reset | A rising edge resets warnings (no effect on errors, which are reset using "Fault Reset"; the state machine is not affected by this bit) |
| Fault reset | A rising edge resets errors and warnings (see "State machine" on page 2650) |
| Current error detection | 0 ... Current error detection disabled 1 ... Current error detection enabled |
| ABR counter sync/async | 0 ... Value of the ABR counter on the "Current position (acyclic)" on page 2646 register. Internal position counter of the ramp generator on the "Current position (cyclic)" register. 1 ... Value of the ABR counter on the "Current position (cyclic)" on page 2644 register. Internal position counter of the ramp generator on the "Current position (acyclic)" register. |
| Stall detection | 0 ... Stall detection disabled 1 ... Stall detection enabled |

Status word

The individual bits of this register and its states depend on the current state of the state machine:

| Status | Reserved / MotorLoadBit 2 ¹⁾ | Reserved / MotorLoadBit 1 ¹⁾ | Reserved / MotorLoadBit 0 ¹⁾ | Reserved | Int. limit active | Target reached | Remote | Reserved | Warning | Switch on disabled | Quick stop | Voltage enabled | Fault | Operation enabled | Switched on | Ready to switch on |
|------------------------|---|---|---|----------|-------------------|----------------|--------|----------|---------|--------------------|------------|-----------------|-------|-------------------|-------------|--------------------|
| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Not ready to switch on | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 0 | 0 | 0 | 0 |
| Switch on disabled | x | x | x | x | x | x | 1 | 0 | x | 1 | x | 0 | 0 | 0 | 0 | 0 |
| Ready to switch on | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 0 | 0 | 0 | 0 | 1 |
| Switched on | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 1 | 0 | 0 | 1 | 1 |
| Operation enable | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 1 | 0 | 1 | 1 | 1 |
| Quick stop active | x | x | x | x | x | x | 1 | 0 | x | 0 | 0 | 1 | 0 | 1 | 1 | 1 |
| Fault reaction active | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 1 | 1 | 1 | 1 |
| Fault | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 1 | 0 | 0 | 0 |

- 1) If bit 7 is set to 1 in the "Mixed Decay / Stall Detection" on page 2635 register, then the motor load value is returned in bits 13-15 of the status word. Otherwise these bits are always 0.

Information about the status word:

| | | |
|--|--|--|
| Bits 0,1,2,3,5 and 6 (light gray in the previous table) | These bits are set according to the current state of the State machine . | |
| Voltage enabled | Becomes 1 as soon as the motor is powered | |
| Warning | Becomes 1 if a warning is detected ("Overcurrent", "Undercurrent"). The type of warning is indicated in the " Error code " on page 2647 register. The highest priority error / warning is shown in each case, with the priority corresponding to the order in the respective table. Warnings can be reset with a rising edge on the "Warning reset" bit in the control word. | |
| Remote | Always 1 since there is no local mode on the SM module | |
| Target reached ¹⁾ , depending on bit 8 (Halt) in the register "Control word" on page 2648 | <p>If Halt = 0</p> <p>In modes 1, -123, -124, -125 and -126 (absolute positioning): 0...Positioning begins 1...Target has been reached</p> <p>In mode 2 (constant speed): 0...Motor accelerates/brakes 1...Speed setpoint reached</p> <p>In modes -127 and -128 (homing): 0...Homing started 1...Homing ended</p> <p>In mode -122 (set actual position): The bit briefly becomes 0 and immediately becomes 1 again as soon as the position is set.</p> | <p>If Halt = 1</p> <p>In all modes: 0...Axis decelerating 1...Axis speed = 0</p> |
| Internal limit active | 0 ... No limit violation 1 ... Internal limit is active (upper/lower software limit violated) | |

Table 511: Information about the status word

- 1) If Halt has not been activated in the "General configuration" on page 2636 register, then "Target Reached" behaves the same as when Halt = 0.

State machine

The motor is controlled according to the state machine illustrated below. After the module is started, the state machine automatically changes to state *"Not ready to switch on"*. The application then operates the state machine by writing commands to the [Control word](#).

The state machine successively reaches states *"Ready to switch on"*, *"Switched on"* and *"Operation enable"* by writing the consecutive commands *"Shutdown"*, *"Switch on"* and *"Enable operation"*.

Information:

Motor movements are performed according to the setting in register **"Mode"** on page 2639 only in state *"Operation enable"*.

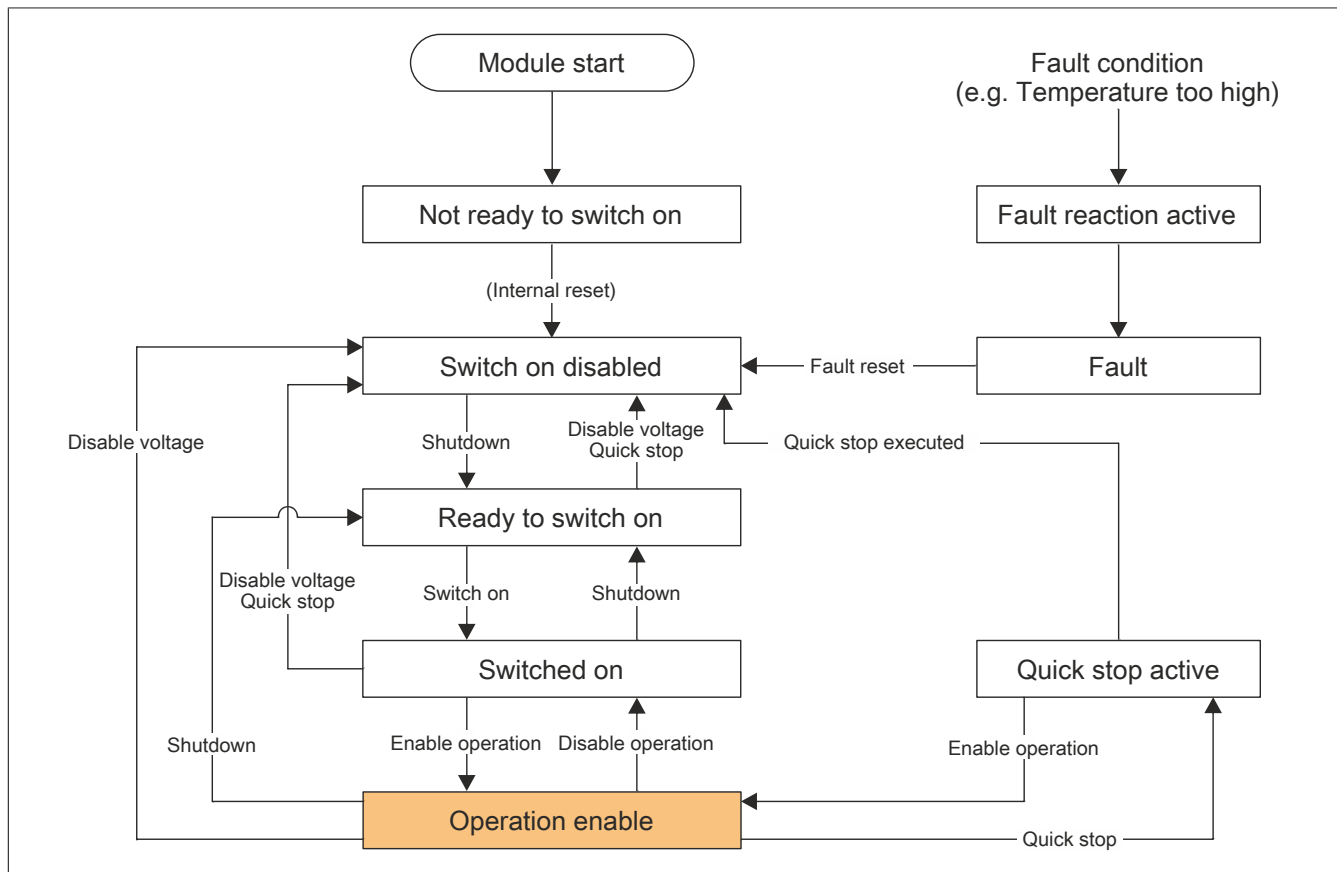

Figure 180: State machine - Flow chart

| State change | Description |
|--|---|
| Not ready to switch on → Switch on disabled | This state change occurs automatically after starting the module and internal initialization has taken place. |
| Switch on disabled → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . No others actions are performed. |
| Ready to switch on → Switch on disabled | This state change is brought on by the command <i>Disable voltage</i> or <i>Quick stop</i> . No others actions are performed. |
| Switched on → Switch on disabled | This state change is brought on by the command <i>Disable voltage</i> or <i>Quick stop</i> . The motor voltage is switched off immediately. |
| Ready to switch on → Switched on | This state change is brought on by the <i>Switch on</i> command. The motor voltage is switched on. When this state change occurs for the first time since the module is started, the motor ID measurement is performed before the <i>Switched on</i> state is achieved. This can take approximately 1 second. |
| Switched on → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . The motor voltage is switched off immediately. |
| Switched on → Operation enable | This state change is brought on by the <i>Enable operation</i> command. Motor movements are now performed depending on the defined mode. |
| Operation enable → Switched on | This state change is brought on by the <i>Disable operation</i> command. If in motion, the motor is decelerated with the configured braking deceleration. Motor voltage remains on in state <i>Switched on</i> . |
| Operation enable → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . The motor voltage is switched off immediately. |

Table 512: State machine - State change

| State change | Description |
|--|--|
| Operation enable → Switch on disabled | This state change is brought on by the <i>Disable voltage</i> command. Motor voltage switched off. It is strongly recommended to only make this state change on a stopped motor since regeneration on a motor running at no load can cause an overvoltage error on the DC bus (0x3210). |
| Operation enable → Quick stop active | This state change is brought on by the <i>Quick stop</i> command. If in motion, the motor is decelerated with the configured braking deceleration. During the deceleration, the state machine remains in state <i>Quick stop active</i> . If the motor comes to standstill, the switch to state <i>Switch on disabled</i> takes place automatically. While the state machine is in state <i>Quick stop active</i> , command <i>Enable operation</i> can be used to switch it back to state <i>Operation enable</i> . |
| → Fault reaction active | This state change is brought on when an error occurs and cannot be triggered by a command from the user. It can be triggered by error types classified as an "Error" (see "Error code" on page 2647). (The other error types classified as "Warning" only cause the "Warning" bit to be set in the status word and do not cause a state change of the state machine.) The motor voltage is cut off and the state machine immediately changes to state <i>Fault</i> . The type of error is listed in the Error code register (see the table under "Error code" on page 2647). The highest priority error is shown. The priority corresponds to the order in the error code table. |
| Fault → Switch on disabled | This state change is brought on by the <i>Fault reset</i> command. However, the state only changes if no more errors are present when the command is written. All errors and warnings are reset. The error code register contains 0 or the warning code if a warning is still present. |

Table 512: State machine - State change

9.25.7.13.10 NetTime Technology

For a description of NetTime Technology, see "NetTime Technology" on page 3035.

9.25.7.13.11 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|---------------------------|--------|
| Function model "Standard" | 250 µs |
| Function model "Ramp" | 250 µs |

9.25.7.13.12 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|---------------------------|--------|
| Function model "Standard" | 250 µs |
| Function model "Ramp" | |
| Inputs | 250 µs |
| Outputs ¹⁾ | 25 ms |

1) Depends on the configuration of the "movement profile generator" on page 2636.

9.25.8 X20SM1436

Data sheet version: 1.51

9.25.8.1 General information

The stepper motor module is used to control stepper motors with a nominal voltage of 24 to 39 VDC ($\pm 25\%$) at a motor current up to 3 A (3.5 A peak). In addition, this module has 4 digital inputs that can be used as limit switches or encoder inputs.

Due to the individual adjustment of the coil currents, the motor is only operated with the current it actually needs. This simplifies the selection of the available motors and prevents unnecessary heating. Because this affects energy consumption and thermal load, the effects are positive on the service life of the complete system. Complete flexibility is achieved through the use of independently adjustable holding, maximum and nominal current values. The current for microsteps is automatically adjusted to the configured current values.

The automatic motor identification system is an enormous help during standstills. The stepper motor modules can identify the connected motors using their coil characteristics and generate feedback in the form of an analog value. This makes it possible to detect not only wiring errors, but also incorrect motor types being used mistakenly. A stall detection mechanism is integrated to analyze the motor load. Detection of the stall is defined via a configurable threshold. This allows an overload or motor standstill to be detected precisely in many different types of applications.

- 1 stepper motor, 24 to 39 VDC $\pm 25\%$, 3 A (3.5 A peak)
- Resolution of current values at 1%
- Boost, nominal and holding current separately configurable
- 38.5 kHz PWM frequency
- Integrated motor detection
- 256 microsteps
- Stall detection
- Complete integration in Automation Studio and CNC applications
- 4 inputs, 24 VDC, configurable for ABR incremental encoders
- Function model "Ramp" based on CANopen communication profile DS402
- NetTime timestamp: Position change, trigger time

NetTime timestamp of the position and trigger time

It is not just the position value that is important for highly dynamic positioning tasks, but also the exact time the position is measured. The module is equipped with a NetTime function for this that supplies a timestamp for the recorded position and trigger time with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.25.8.2 Order data

| Model number | Short description | Figure |

9.25.8.4 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

| Figure | LED | Color | Status | Description |
|--|-------|-----------------------------|------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset state |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1 - 4 | Green | | Input state of the corresponding digital input |
| | M | Orange | On | Motor is active |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.25.8.5 Pinout

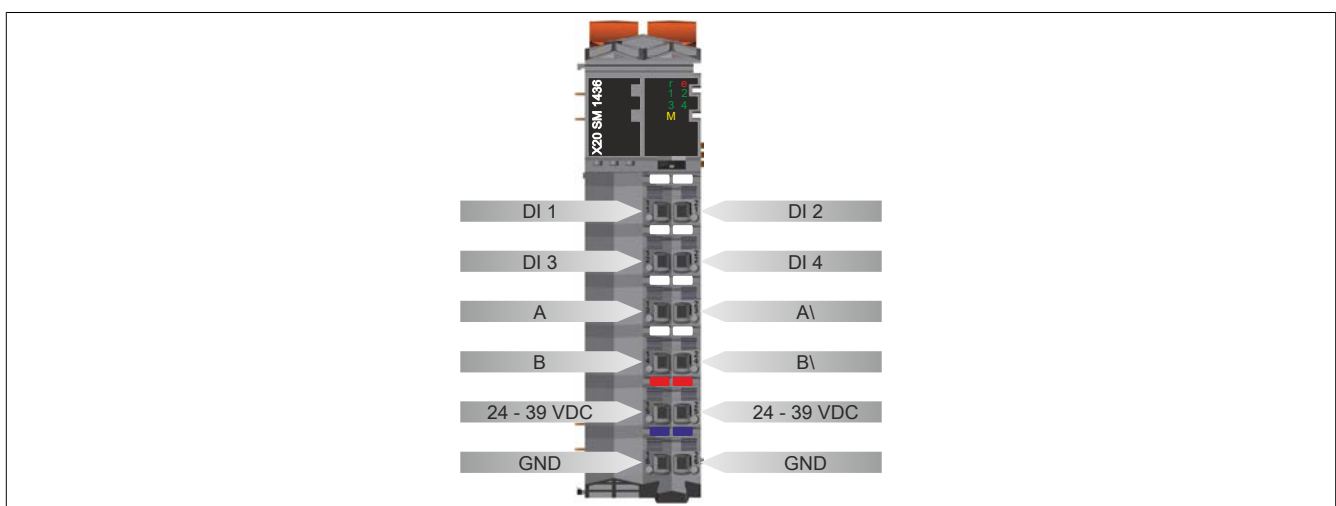

In accordance with the EN 60204-1 standard, a cable cross section of 0.75 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 3.5 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

The terminal block is not permitted to be connected or disconnected during operation.

Information:

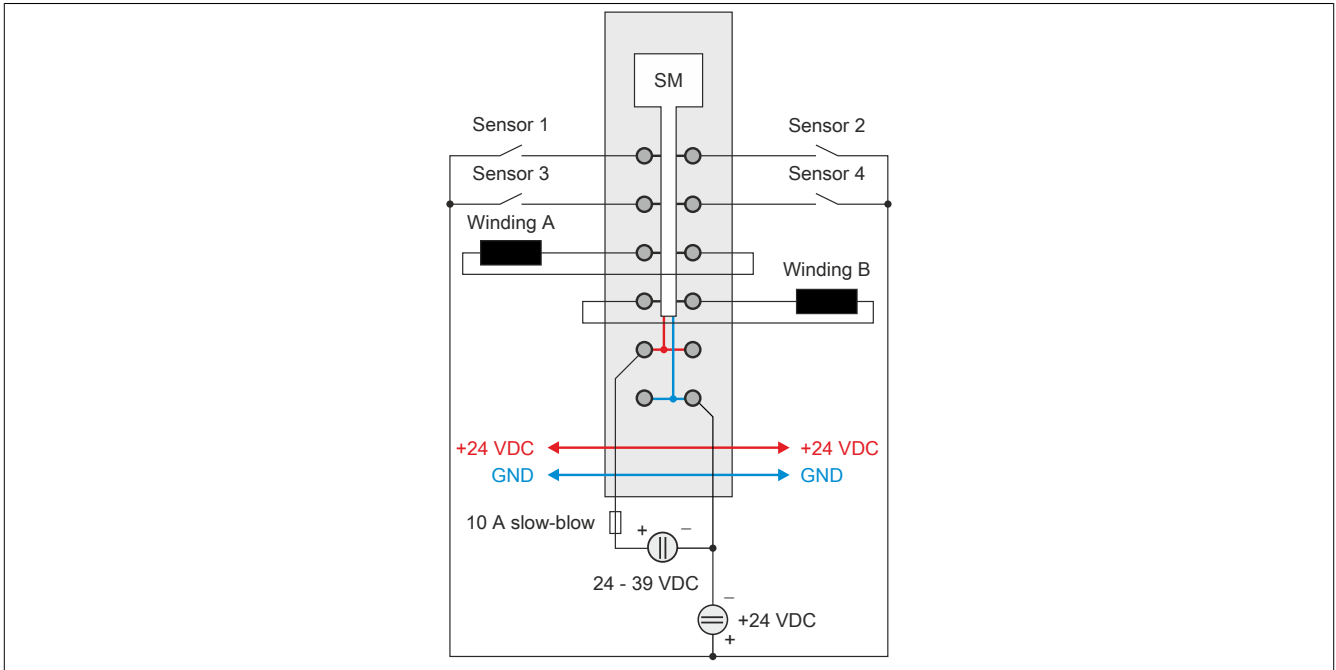

Shielded motor cables must be used in order to meet the limit values per standard EN 55011 (emissions).

9.25.8.6 Connection example

Information:

This module can only be operated if supplied with power via the terminal block.

9.25.8.7 Connection options for digital inputs

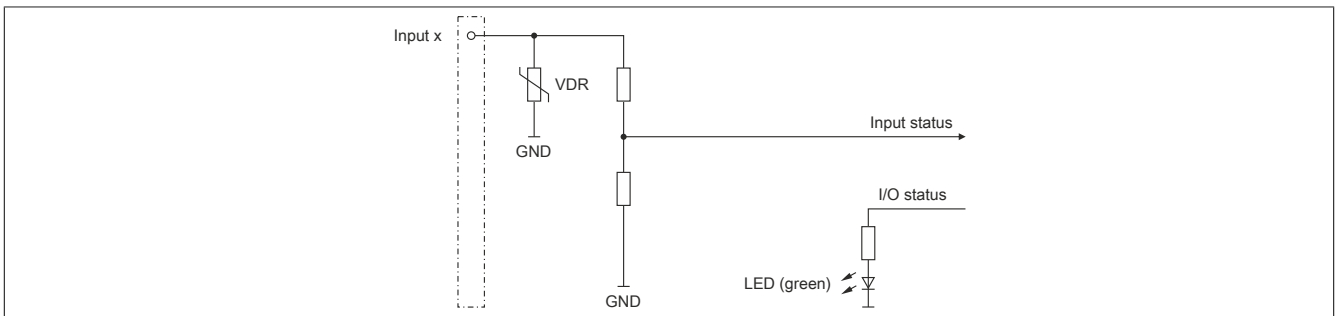

Function model "Standard"

| Channel | Function |
|---------|-----------------|
| DI 1 | Digital input A |
| DI 2 | Digital input B |
| DI 3 | Digital input R |
| DI 4 | Trigger input |

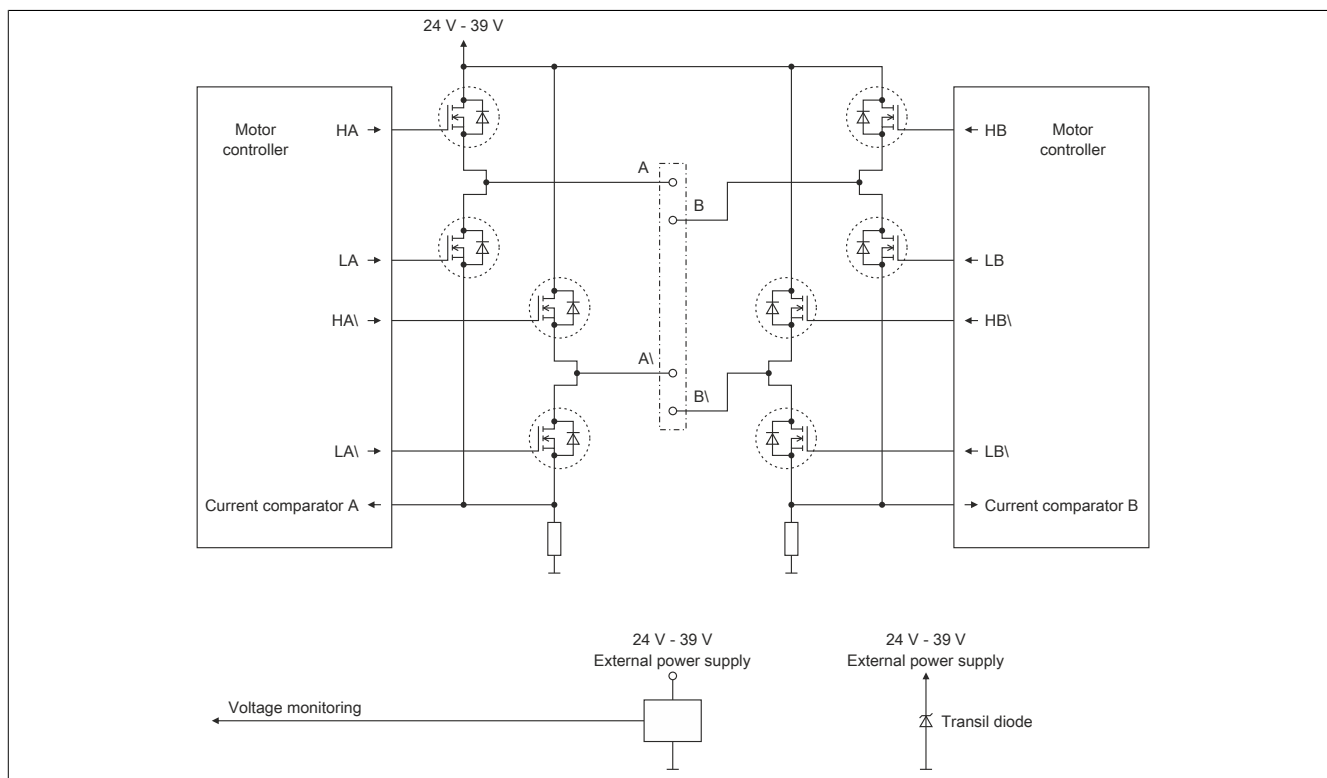

Function model "Ramp"

| Channel | Function |
|---------|-------------------------------------|
| DI 1 | Digital input A |
| DI 2 | Digital input B |
| DI 3 | Digital input R |
| DI 4 | Digital input Negative limit switch |

9.25.8.8 Input circuit diagram

9.25.8.9 Output circuit diagram

9.25.8.10 Overvoltage motor cutoff

The module supply voltage is continually monitored. Its status can be read. The error "Module power supply error" occurs when the voltage is above or below the limits.

If the supply voltage on the module rises or falls outside the limit values (e.g. due to regeneration), then the motor output is switched off.

The outputs are reactivated as soon as the supply voltage is back in the valid range and the error bit is reset.

Supply voltage limit values

| | Drive is switched off | Drive is switched back on |
|-------------|-----------------------|---------------------------|
| Lower limit | <18 V | >19.5 V |
| Upper limit | >50 V | <49 V |

9.25.8.10.1 Energy regeneration of the voltage

If voltage is regenerated during generator operation of the motor, the built-in Transil diode may be overloaded and the module could be irreparably damaged as a result. The following recovery values are therefore not permitted to be exceeded:

- 6 W at more than 53 V

Notice!

Overshoot of the limit values must not be avoided by means of suitable technical measures or by disconnecting cables during maintenance work.

9.25.8.11 Shutdown in the event of overtemperature (starting at 85°C)

If the module temperature reaches or overshoots the limit value of 85°C, the module performs the following actions:

- Sets the "overtemperature" error bit
- Cuts off the outputs (short-circuited)

As soon as the temperature is reduced below 85°C again, the error must be acknowledged with "OvertemperatureAcknowledge" so that the channels can be switched on again.

9.25.8.12 Power supply dimensioning

The motor's current consumption depends on the defined motor currents, the available power and the actual motor being used.

| Example | |
|-------------------------------------|-------------------|
| Motor model number | 80MPD5.300S000-01 |
| Defined current in the motor module | 3 A |
| Motor module supply voltage | 48 VDC |
| Motor load | 1 Nm |

Table 515: Power supply dimensioning example - Basic data

Figure 181: Power supply dimensioning example - Power/Speed relationship

The example is based on a constant load throughout the entire speed range.

An increase in the motor load causes an increase in the effective current of the I/O power supply.

9.25.8.13 Fuse protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load but is always less than the motor current. Make sure the maximum nominal current of 10 A is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the mains power input and the rated current of the used fuse are chosen according to the current-carrying capacity such that the permissible current-carrying capacity of the selected cable cross section (depending on wiring, see table) is greater than or equal to the current load in the mains power input. The rated current of the fuse protection must be less than or equal to the permissible current-carrying capacity of the selected cable cross section (depending on the how it is installed, see table):

$$I_{\text{Power system}} \leq I_{\text{Fuse}} \leq I_{\text{Line/cable}}$$

| Wire cross section [mm ²] | Current-carrying capacity of cable cross section I_z / rated current of fuse I_b [A] depending on the to type of wiring at an ambient air temperature of + 40°C per EN 60204-1 | | | |
|---------------------------------------|--|-----------|-----------|-----------|
| | B1 | B2 | C | E |
| 1.5 | 13.5 / 13 | 13.1 / 10 | 15.2 / 13 | 16.1 / 16 |
| 2.5 | 18.3 / 16 | 16.5 / 16 | 21 / 20 | 22 / 20 |

Table 516: Cable cross section of the mains power input depending on the type of wiring

The tripping current of the fuse is not permitted to exceed the rated current of the fuse I_b .

| Type of wiring | Description |
|----------------|--|
| B1 | Wires in conduit or cable duct |
| B2 | Cables in conduit or cable duct |
| C | Cables or wires on walls |
| E | Cables or wires on open-ended cable tray |

Table 517: Type of wiring used for the mains power input

9.25.8.14 Derating

Only modules with a maximum power dissipation of 1 W are permitted to be operated next to the SM module. To ensure proper operation, observe the derating values listed below.

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

Power dissipation derating for neighboring modules

Modules directly next to the SM module can have a power loss of 1 W. If the SM module is operated at the rated load over the entire temperature range (3 A rated current), the power loss of neighboring modules must be derated starting at 45°C.

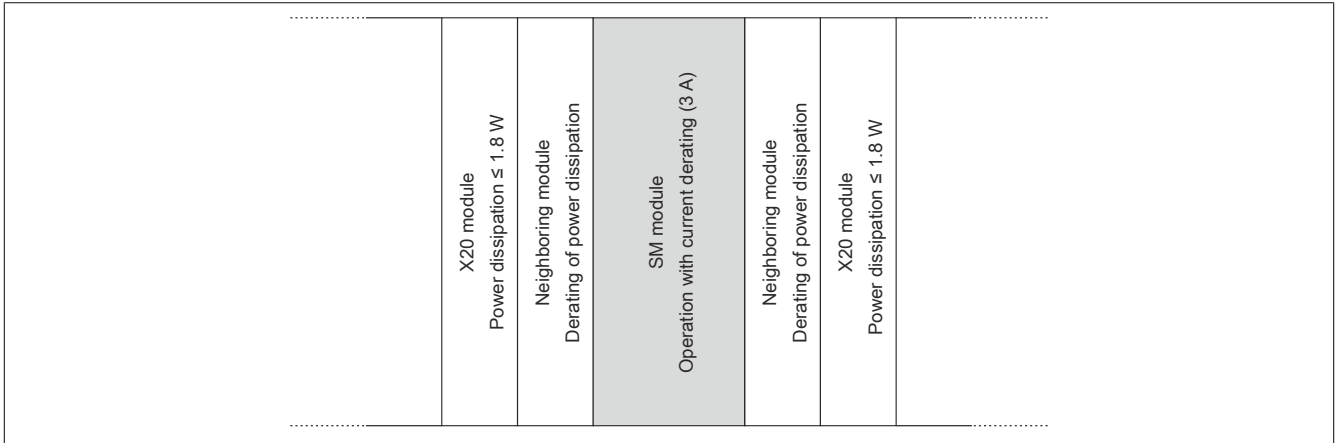

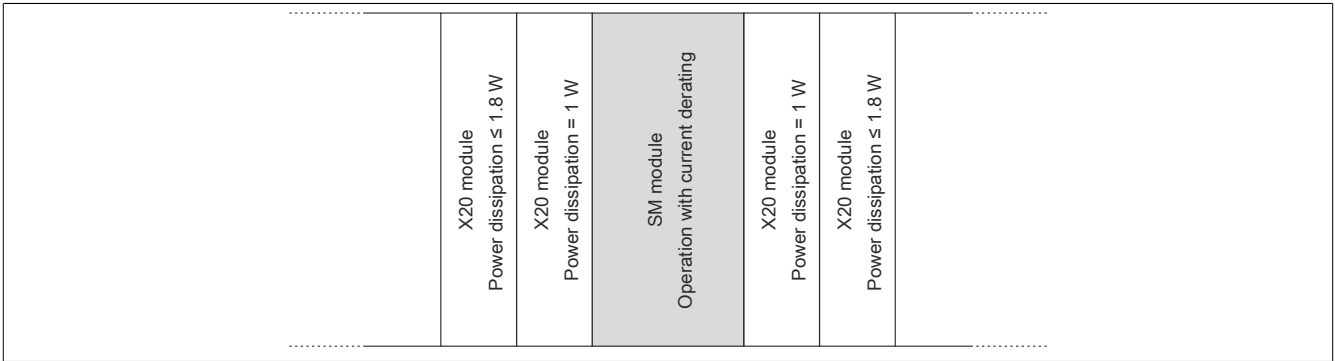

Figure 182: Operating the SM module over the entire temperature range at 3.0 A rated current

Current derating of the SM module

If the power loss of the neighboring modules to the SM module is 1 W, then the current of the SM module must be derated starting at 45°C.

Hardware configuration for multiple SM modules

If three or more SM modules are operated in a cluster, a dummy module must be inserted between the SM modules. There is no derating in this configuration.

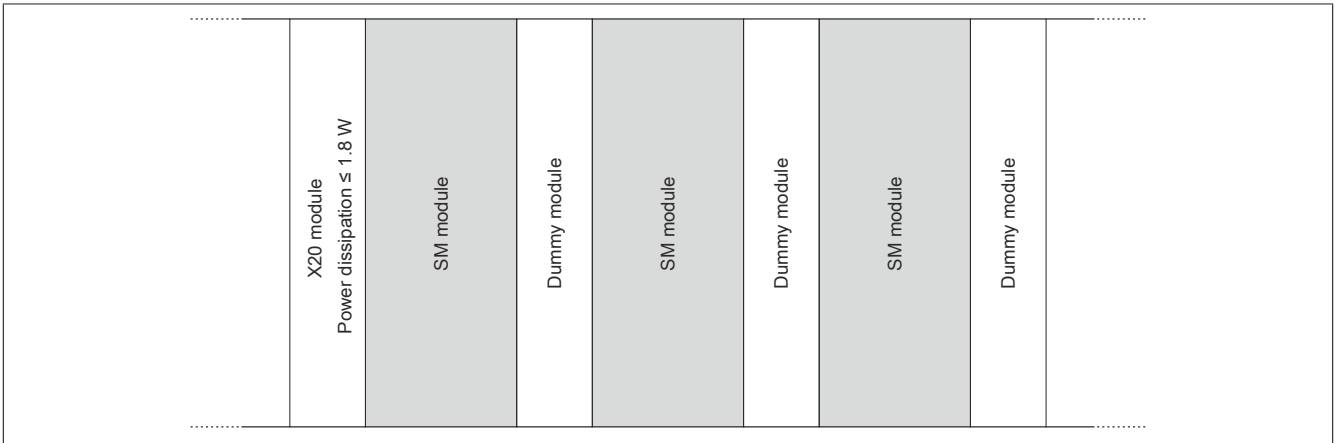

Figure 183: Operating three or more SM modules in a cluster

9.25.8.15 Register description

9.25.8.15.1 mapp Motion system requirements

This module can be operated with mapp Motion function blocks. The following minimum versions are required for this:

- Upgrade version 2.2.0.0
- Automation Studio 4.7.2
- Automation Runtime 4.72

9.25.8.15.2 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "General data points" on page 3790.

1) The offset specifies the position of the register within the CAN object.

9.25.8.15.5.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "Using I/O modules on the bus controller" on page 3789.

9.25.8.15.5.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN I/O.

9.25.8.15.6 Register description: Function model "Standard", general registers**9.25.8.15.6.1 Configuration registers****Stall threshold**

Name:

ConfigOutput01

The SM module features integrated sensorless load measurement for the motor axis. This is especially useful for detecting a "stall condition" (e.g. if the motor moves to the end point during a homing procedure). It cannot be used for torque monitoring during dynamic movements.

With the "stall threshold" register, a threshold can be defined according to the motor load, and the module detects a stall condition started at this threshold (see "[Error status](#)" on page 2671).

This threshold value must be determined on a case-by-case basis, since the results of load measurement are influenced by a variety of factors.

- Motor speed: A higher speed results in higher measurement values
- Speeds that cause motor resonances (which interfere with load measurement) are to be avoided
- Motor accelerations that create a dynamic load (and also affect the measurement) should also be avoided
- It is especially important to be aware that mixed decay mode must be optimized for reliable stall detection (see "[Mixed decay threshold](#)" on page 2665)

The higher the load measurement value, the lower the load. This means that a stall condition is detected if the load measurement value drops below the trigger threshold for stall detection.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------------------------------|--------|--|
| 0 - 2 | Trigger threshold for stall detection | 0 | Stall detection is disabled |
| | | 1 | Minimum sensitivity for stall detection |
| | | 2 to 6 | Setting the sensitivity of stall detection |
| | | 7 | Maximum sensitivity for stall detection |
| 3 - 15 | Reserved | 0 | |

Mixed decay threshold

Name:

ConfigOutput16

The mixed decay threshold is configured in this register. This value must be adjusted according to the motor being used, current and voltage when using [stall detection](#). Otherwise, the default value 15 will be used.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|-----------------------|---------|-----------------------------------|
| 0 - 3 | Mixed Decay Threshold | 0 | Mixed decay disabled |
| | | 1 to 14 | Setting for mixed decay threshold |
| | | 15 | Mixed decay always enabled |
| 4 - 15 | Reserved | - | |

Mixed decay modules provide a greatly optimized sinusoidal current profile in the individual phases of the stepper motor, especially for fast current changes and low current values.

Mixed decay interferes with reliable stall detection, however. For this reason, mixed decay mode can be disabled during stall detection (motor load measurement) using the mixed decay threshold. The smaller the configured mixed decay threshold, the larger the range in which mixed decay is disabled while motor load measurement takes place.

Mixed decay mode is always enabled if the mixed decay threshold is set to 15.

Relationship between stall detection and mixed decay

Depending on the application and the motor used, satisfactorily smooth operation can be achieved while using stall detection by setting the mixed decay threshold to a value between 1 and 14. This is a compromise between smooth operation and stall detection quality and must be fine tuned during commissioning.

Minimum speed for stall detection

Name:

StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled and the configured [mixed decay threshold](#) is used. The value 15 is always used for the mixed decay threshold below this threshold value, and no stall error is reported. This means that mixed decay mode is always enabled at low speeds where stall detection principally does not work.

| Data type | Values | Information |
|-----------|-------------|------------------------------------|
| UINT | 0 to 65,535 | Minimum speed in steps per second. |

Full step threshold

Name:

FullStepThreshold01

This register configures a rotational speed. When this defined speed has been reached, the drive will automatically change from microsteps to full step mode. This makes it possible to optimize the torque at higher speeds, while microstep mode ensures optimal radial runout at lower speeds.

It does not make sense to change to full step mode at a standstill because fine positioning would then no longer be possible. This is why value "0" does not make sense in the full step threshold register and is interpreted as disabling full step mode (i.e. the motor will always be operated in microstep mode).

| Data type | Values | Information |
|-----------|-------------|-------------------------|
| UINT | 0 | Full step mode disabled |
| | 1 to 65,535 | Steps/second |

Example

Microstep mode should change to full step mode at 500 steps/second. On a motor with 200 steps per revolution, this would be equal to a speed of:

$$T^{-1} = \frac{500 \text{ steps/second}}{200 \text{ steps/revolution}} = 2.5 \frac{\text{revolutions}}{\text{second}} = 150 \text{ min}^{-1}$$

Holding current, nominal current and maximum current

Name:

ConfigOutput03 (holding current)

ConfigOutput04 (nominal current)

ConfigOutput05 (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

Information:

The maximum current must always be configured higher than the nominal current.

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

| Register | Description |
|-----------------|---|
| Nominal current | Current during normal operation |
| Maximum current | Should be selected if a higher motor torque is required briefly during acceleration phases. |
| Holding current | The holding current should be used in situations when less torque is required (e.g. at a standstill). This reduces the amount of heat generated by the motor. |

Switching between preset current values (holding current, rated current, maximum current):

| Function model | Switching between preset current values at runtime |
|---------------------------------------|--|
| Standard | Using bits 14 and 15 in registers "Motor StepX" on page 2672 |
| Standard with enabled SDC information | Using register "Motor current" on page 2677 |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 120 | Percent of the module's rated current <ul style="list-style-type: none"> • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 120% corresponds to the maximum current of the motor bridge power unit listed in the technical data. |

Counter configuration

Name:

ConfigOutput09

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------------|-------|--|
| 0 | ABR latch function | 0 | Negative edge: Disable ABR latch function |
| | | 1 | Positive edge: Enable ABR latch function. After a latch event has occurred, the latch function can be started again on a new rising edge. |
| 1 - 2 | Definition of the latch mode | 00 | ABR latch counter state unconditionally |
| | | 01 | ABR latch counter state on a positive edge of input R |
| | | 10 | ABR latch counter state on a negative edge of input R |
| | | 11 | Reserved |
| 3 | | 0 | <ul style="list-style-type: none"> • Position sync: Internal position counter • Position async: ABR counter state • Position latched sync: Internal position counter • Position latched async: ABR counter state |
| | | 1 | <ul style="list-style-type: none"> • Position sync: ABR counter state • Position async: Internal position counter • Position latched sync: ABR counter state • Position latched async: Internal position counter |
| 4 - 7 | Reserved | | |

1) These registers are not available in function model "Standard" with SDC information enabled.

Motor ID trigger

Name:

MotorIdentTrigger

With this register, a measurement of the motor ID can be initiated acyclically (see ["Motor identification" on page 2670](#)). The application must ensure that the conditions for measurement are met (see table "Notes" in register ["Motor identification" on page 2670](#)).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|---|
| 0 | | 0 | No effect |
| | | 1 | Positive edge triggers motor identifier measurement |
| 1 - 7 | Reserved | 0 | |

9.25.8.15.6.2 Registers for reading back the configuration

Reading back the holding current, nominal current and maximum current

ConfigOutput03Read (holding current)

ConfigOutput04Read (nominal current)

ConfigOutput05Read (maximum current)

These registers are used to read the respective current values in percent.

| Register | Description |
|-----------------|--|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases |
| Holding current | Current when motor is at standstill |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 255 | Percentage of module's nominal current (100% corresponds to the nominal current of the motor bridge power unit in the technical data) |

9.25.8.15.6.3 Communication registers**Measuring motor load**

Name:
MotorLoad

Dieses Register enthält den aktuellen Lastmesswert der Stall Detection. Kann zum Abstimmen der Stall Detection verwendet werden.

| Data type | Values |
|-----------|---------|
| USINT | 0 bis 7 |

Module configuration 1

Name:
ConfigOutput02

The number of transfer values and the resolution of microsteps for the drive can be configured in this register.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 | The setting for these two bits determines the meaning of bits 2 and 3 in register "Input counter value" on page 2674. | x | |
| 1 - 2 | Reserved | 0 | |
| 3 - 4 | Number of transfer values per X2X Link cycle (see "Motor StepX" on page 2672) | 00 | 1 x $\Delta s / \Delta t$ (transfer values: MotorStep0) |
| | | 01 | 2 x $\Delta s / \Delta t$ (transfer values: MotorStep0 - MotorStep1) |
| | | 10 | 4 x $\Delta s / \Delta t$ (transfer values: MotorStep0 - MotorStep3) |
| | | 11 | Reserved |
| 5 - 6 | Resolution of microsteps for the following registers: <ul style="list-style-type: none"> "Motor StepX" on page 2672 "Position sync/async" on page 2669 | 00 | Resolution: 5 bits (bits 0 - 4) microsteps; 8 bits (bits 5 - 13) full steps |
| | | 01 | Resolution: 6 bits (bits 0 - 5) microsteps; 7 bits (bits 6 - 13) full steps |
| | | 10 | Resolution: 7 bits (bits 0 - 6) microsteps; 6 bits (bits 7 - 13) full steps |
| | | 11 | Resolution: 8 bits (bits 0 - 7) microsteps; 5 bits (bits 8 - 13) full steps |
| 7 - 15 | Reserved | 0 | |

Position sync/async

Name:

PositionSync

Positionasync

Depending on the [Counter configuration](#), these registers can be used to read either the internal position counter or the counter value on the ABR input.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

| Register | Counter configuration | |
|----------------|---------------------------|---------------------------|
| | Bit 3 = 0 | Bit 3 = 1 |
| Position sync | Internal position counter | ABR counter |
| Position async | ABR counter | Internal position counter |

Internal position counter

The internal position counter is the position calculated by the SM module (position setpoint). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the ["Module configuration 1" on page 2668](#)). In function model "Standard" with SDC, this value is defined as **"8-bit microstep"** and cannot be changed.

Example of the internal position counter format (7-bit microsteps, i.e. set bit 5 and 6 of the module configuration to binary 10):

ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

Motor identification

Name:

Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. After successful measurement, this register contains the time [µs] required to apply a current increase of $\Delta I = 1 \text{ A}$ to a motor winding.

This depends on:

- Operating voltage
- Inductance and resistance of the motor winding

| Notes | |
|-------|---|
| 1) | To achieve reproducible results, the measurement must be made under the following defined conditions: |
| a) | Motor is at standstill. |
| b) | The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: <ul style="list-style-type: none"> • Full steps are divisible by 4. • Microsteps = 0 |
| 2) | Condition 1b) is fulfilled after a the SM module is reset or switched on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application. |
| 3) | The current range from approximately 1/3 of the nominal current up to the nominal current is used as operating range for determining the motor identifier. |

| Data type | Motor ID values | Explanation |
|-----------|-----------------|--|
| UINT | 0 | No motor identifier available (after switching on for as long as the measurement conditions are not met) |
| | 1 to 32767 | Valid range of values for the motor ID register (in µs) |
| | 65504 to 65519 | Ground fault: Measurement of motor identification not possible |
| | 65528 | Motor ID trigger not possible <ul style="list-style-type: none"> • Motor not supplied with current • Motor in movement • Nominal current set to 0 A • Ground fault present |
| | 65529 | Invalid value: Underflow |
| | 65530 | Overtemperature: Measurement not possible |
| | 65532 | Open circuit: Measurement not possible |
| | 65533 | Incorrect motor position: Measurement not possible |
| | 65534 | Invalid value: Overflow |
| | 65535 | Measurement in progress |

Ground fault detection

When the motor is powered on, a ground fault check is performed before motor identification. Error numbers have been added in the motor identification register for the event of a ground fault error (values 65504 to 65519 in the table above).

Error status

Name: The names of the bits are different depending on whether [SDC information](#) is enabled or disabled.

| Without SDC | With SDC |
|--------------------------------|---------------------|
| StallError | StallError01 |
| Overtemperature | Overtemperature01 |
| ErrorCurrentError | ErrorCurrentError01 |
| OvercurrentError | OvercurrentError01 |
| - | DrvOK01 |
| OpenCircuit01 to OpenCircuit04 | |

The current error status of the drive is indicated in this register. Each bit indicates a certain error or status. If an error is registered in bits 0 to 3, then the corresponding bit remains set until the error has been acknowledged (see ["Module configuration 2" on page 2675](#) and ["Error acknowledgment" on page 2678](#)).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|---|
| 0 | StallError(01) | 0 | No stall |
| | | 1 | Stall |
| 1 | Overtemperature error OvertemperatureError(01) | 0 | No overtemperature |
| | | 1 | Overtemperature |
| 2 | Current error CurrentError(01) | 0 | No current error |
| | | 1 | Current error |
| 3 | Overcurrent error OvercurrentError(01) | 0 | No overcurrent |
| | | 1 | Overcurrent |
| 4 | Status of the drive DrvOk0 ¹⁾ | 0 | An error was triggered for the motor axis |
| | | 1 | The drive is running error-free |
| 5 - 15 | Reserved | 0 | |

1) Only when SDC information is enabled

Overtemperature error

The "Overtemperature" error bit can be set for the following reasons:

- A specific temperature was exceeded near the channel due to overload
- The module temperature rises above the 85°C.

Current error

This error bit occurs whenever the required current cannot be supplied to the motor windings. This can be (but is not necessarily) caused by an open circuit. At higher speeds (depending on the motor), this error can also occur without an open circuit. In this case it is simply no longer possible to supply the desired current to the motor windings. Because of the Back-EMF on the motor, this bit is set at slightly lower speeds if the motor is operated with no load compared with full or partial loads.

Overcurrent error

Overcurrent occurs if the motor current measured in the motor windings is twice as high as it should be (e.g. short circuit).

Status of the drive

The status of the drive is only shown when SDC information is enabled. The drive bit is 1 when the following conditions are met:

- Motor turned on (see ["Motor current" on page 2677](#))
- Ground fault detection is completed and OK
- MotorID measurement is completed
- Motor is supplied with current
- Motor settling time has passed
- Supply voltage is in the valid range
- No overtemperature fault
- Preset position value is valid (see ["SDC life sign monitoring" on page 2677](#))

9.25.8.15.7 Register description: Function model "Standard" without SDC information

9.25.8.15.7.1 Communication registers

Motor StepX

Name:

MotorStep0 to MotorStep3

These registers specify the number and direction of steps that must be moved by the module during the next X2X cycle and also select the motor current (see also "[Holding current, nominal current and maximum current](#)" on page 2666).

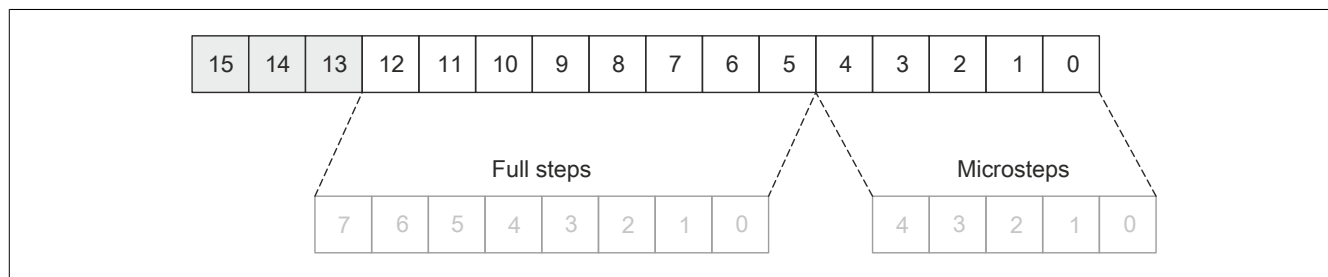

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|-------|-------------------|
| 0 - 12 | Number of steps for the module to move during the next X2X cycle | x | |
| 13 | Direction of movement | 0 | Positive |
| | | 1 | Negative |
| 14 - 15 | Selection of motor current | 00 | Motor not powered |
| | | 01 | Holding current |
| | | 10 | Nominal current |
| | | 11 | Maximum current |

Depending on the necessary resolution and maximum configurable speed, module configuration 1 can be used to specify which bit position is used as the 1s position for full steps (see bits 5 and 6 of "[Module configuration 1](#)" on page 2668).

Example for 5-bit microsteps (set bits 5 and 6 of the module configuration to binary 00):

The number of transfer values per X2X cycle is specified by bits 3 and 4 in the module configuration 1 (see "[Module configuration 1](#)" on page 2668). If only one transfer value (bits 3 and 4 = 00) is specified, then the motor is advanced by MotorStep0 until the next X2X cycle. If 2 or 4 transfer values are specified, then the X2X cycle is divided accordingly.

Example: X2X cycle = 1 ms (1000 μ s)

| Time | Number of transfer values (see " Module configuration 1 " on page 2668) | | |
|---------------------|---|---------------------|---------------------|
| | 1 (bits 3 - 4 = 00) | 2 (bits 3 - 4 = 01) | 4 (bits 3 - 4 = 10) |
| 0 - 250 μ s) | MotorStep0 | MotorStep0 | MotorStep0 |
| 250 - 500 μ s) | | | MotorStep1 |
| 500 - 750 μ s) | MotorStep1 | MotorStep1 | MotorStep2 |
| 750 - 1000 μ s) | | | MotorStep3 |

Position latched sync-async

Name:

PositionLatchedSync

PositionLatchedASync

The position counter (internal position counter or ABR counter) is applied at the latch event (see "Module configuration 2" on page 2675). Bits 3 and 7 of register "Counter configuration" on page 2667 are used to determine which counter state (internal position counter or ABR encoder) should be saved in registers "Position latched sync" and "Position latched async".

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

| Register | Counter configuration | |
|----------------|---------------------------|---------------------------|
| | Bit 3 = 0 | Bit 3 = 1 |
| Position sync | Internal position counter | ABR counter |
| Position async | ABR counter | Internal position counter |

Internal position counter

The internal position counter is the position calculated by the module (position setpoint). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the "Module configuration 1" on page 2668).

Example of the internal position counter format (7-bit microsteps, i.e. set bit 5 and 6 of the module configuration to binary 10):

ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

usSinceTrigger

Name:

usSinceTrigger

This register indicates the time in μs that has passed since the trigger event occurred (see "Module configuration 2" on page 2675).

Information:

The absolute accuracy of the trigger can be delayed up to 5 μs due to the input filter of the digital inputs.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Stepper latch trigger status

Name:

LatchInput

LatchDone

TriggerInput

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|---|
| 0 | Latch input: | x | Digital input for the latch event (level) |
| 1 | LatchDone | x | Changes its state each time the counter state is successfully latched (reset value = 0) |
| 2 - 3 | Reserved | - | |
| 4 | TriggerInput | x | Trigger input (level) |
| 5 - 7 | Reserved | 0 | |

9.25.8.15.7.2 Input counter value

Name:

ModulePowerSupplyError

StatusInput01 to StatusInput04

This register indicates the state of the digital inputs and counters.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|---|--|
| 0 | ModulePowerSupplyError | 0 | OK |
| | | 1 | Module power supply error |
| 1 | Reserved | 0 | |
| 2 | StatusInput01 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 1 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | x | Ref toggle bit for counter 1: The state of this bit is changed after homing is completed. |
| 3 | StatusInput02 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 2 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | 0 | The homing procedure for the ABR counter is active. |
| | | 1 | The homing procedure of the ABR counter is completed. |
| 4 | StatusInput03 | 0 or 1 | Input state - Digital input 3 |
| 5 | StatusInput04 | 0 or 1 | Input state - Digital input 4 |
| 6 - 7 | Reserved | 0 | |

9.25.8.15.7.3 Configuration registers

Module configuration 2

Name:
 StartLatch
 TriggerEdgePos
 TriggerEdgeNeg
 StartTrigger
 TriggerEdge
 ClearError

The trigger functions for the stepper motor can be configured with this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|---|
| 0 | Latch function for stepper motor 2 Latch byte | 0 | The latch function for stepper motor position is disabled on the negative edge of this bit. |
| | | 1 | The latch function for stepper motor position is disabled on the positive edge of this bit. |
| 1 - 2 | Latch mode for stepper motor TriggerEdgePos (bit 1) TriggerEdgeNeg (bit 2) | 00 | Latch position of stepper motor unconditional |
| | | 01 | Latch position of stepper motor on positive edge of input DI 3 |
| | | 10 | Latch position of stepper motor on negative edge of input DI 3 |
| | | 11 | Reserved |
| 3 | TriggerEdge | 0 | Trigger edge (input DI 4) = Positive |
| | | 1 | Trigger edge (input DI 4) = Negative |
| 4 | Enable trigger (on change) StartTrigger | x | |
| 5 | ClearError | 0 | No effect |
| | | 1 | Error acknowledgment for motor (for more information, see "Error status" on page 2671) |
| 6 - 7 | Reserved | - | |

Trigger function procedure:

- Selection of the desired trigger edge using bit 3
- Enabling of the trigger function by changing the state of bit 4. Changing this bit deletes `usSinceTrigger` (μ s counter).
- When the trigger event occurs, μ s counter `usSinceTrigger` is started.
- Counter `usSinceTrigger` cannot overflow, i.e. the counter is stopped at $2^{16} - 1$ and retains this value until the next time the trigger function is enabled.

The trigger function can be re-enabled at any time by changing the state of bit 4, regardless of whether a trigger event has occurred or if `usSinceTrigger` has reached the maximum value.

Position sync 2

Name:
 PositionSync02

This register contains the state of either the position counter or the ABR counter depending on [Counter configuration](#) (bit 3). It behaves exactly complementary to register "Position sync" on page 2669.

If "Position sync" contains the position counter, then register "PositionSync02" contains the ABR counter state, and vice versa.

By default, the register is not visible in the I/O map; it must first be enabled in the I/O configuration.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.8.15.8 Register description: Function model "Standard" with SDC information

9.25.8.15.8.1 Configuration registers

SDC configuration

Name:
SDCConfig01

This register can be used to enable/disable additional SDC information.

The additional cyclic registers are hidden or shown depending on whether SDC information is disabled or enabled. Compare the two variants of function model "Standard" [with](#) and [without enabled SDC information](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|----------------------|
| 0 | Trigger edge | 0 | Rising trigger edge |
| | | 1 | Falling trigger edge |
| 1 - 5 | Reserved | 0 | |
| 6 | SDC life sign monitoring | 0 | Disabled |
| | | 1 | Enabled |
| 7 | SDC information ¹⁾ | 0 | Disabled |
| | | 1 | Enabled |

- 1) When the "SDC information" bit is enabled, the "EncOK01" bit is shown in the Automation Studio I/O mapping. This bit is linked to the ModulOK bit and always indicates its value.

Information:

Neither SDC information nor SDC life sign monitoring is permitted to be changed at runtime.

Module configuration 1 with SDC

Register "[Module configuration 1](#)" on [page 2668](#) is ignored in function model "Standard" with SDC information enabled. The module behaves as follows, i.e. whether the module configuration was written in this way:

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 | Meaning of bits 2 and 3 in register " Input counter value " on page 2678 | | |
| 1 - 2 | Reserved | 0 | |
| 3 - 4 | Number of transfer values per X2X cycle | 00 | 1x Δs / Δt (transfer values: motor settings Motor1Step0) |
| 5 - 6 | Resolution of microsteps | 11 | 8-bit microsteps |
| 7 - 15 | Reserved | 0 | |

Motor settling time

Name:
MotorSettlingTime01

This register determines the motor setting time. The motor settling time determines the minimum time between when the motor is powered on to when the DrvOk bit is set (see "[Error status](#)" on [page 2671](#)). The setting is made in steps of 10 ms.

| Data type | Values | Information |
|-----------|----------|---------------------------------|
| USINT | 1 to 255 | 10 ms to 2.55 s, default: 10 ms |

Switch-off delay

Name:
DelayedCurrentSwitchOff01

If the [SDC life sign monitoring](#) is triggered (i.e. the [NetTime timestamp](#) is in the past) the motor is decelerated at nominal current with speed setpoint = 0.

Then the motor is switched off after the delay configured with this register.

| Data type | Values | Information |
|-----------|----------|--|
| USINT | 0 to 255 | 0 to 25.5 s in steps of 100 ms (default: 100 ms) |

9.25.8.15.8.2 Communication registers

SDC life sign monitoring

Name:

SetTime01

The module uses SDC life sign monitoring to check whether valid values have been received for the speed setpoint.

SDC life sign monitoring is enabled in register "SDC configuration" on page 2676 by setting bit 6 (SDCSetTime = On).

If the specified [NetTime timestamp](#) is in the past, then an error is triggered for the motor axis (only when the motor is switched on). The module performs the following steps:

- 1) The CPU is informed of the error using the Drive bit (DrvOk) = 0
- 2) Braking at configured nominal current with speed setpoint = 0
- 3) Wait for configured turn-off delay to expire
- 4) Power off motor

When the timestamp is back within the valid range, the motor can be operated again by a rising edge on bit "DriveEnable" (see "[Motor current](#)" on page 2677) .

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Motor current

Name:

DriveEnable01

BoostCurrent01

StandstillCurrent01

Bits 0 to 2 of this register control the motor's current feed.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------------|-------|-----------------|
| 0 | DriveEnable01 | x | Motor powered |
| 1 | BoostCurrent01 | x | Maximum current |
| 2 | StandstillCurrent01 | x | Holding current |
| 3 - 7 | Reserved | 0 | |

The possible status of bits 0 to 2

| StandstillCurrent01 | BoostCurrent01 | DriveEnable01 | Description |
|---------------------|----------------|---------------|-----------------------------------|
| x | x | 0 | Motor not supplied with current |
| 0 | 0 | 1 | Rated current supplied to motor |
| 0 | 1 | 1 | Maximum current supplied to motor |
| 1 | 0 | 1 | Holding current supplied to motor |
| 1 | 1 | 1 | Holding current supplied to motor |

Lifecycle counter

Name:

LifeCnt

This register is incremented by one with each X2X Link cycle.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Input counter value

Name:

ModulePowerSupplyError

StatusInput01 to StatusInput04

This register indicates the state of the digital inputs and counters.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|---|--|
| 0 | ModulePowerSupplyError | 0 | OK |
| | | 1 | Module power supply error |
| 1 | Reserved | 0 | |
| 2 | StatusInput01 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 1 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | x | Ref toggle bit for counter 1: The state of this bit is changed after homing is completed. |
| 3 | StatusInput02 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 2 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | 0 | The homing procedure for the ABR counter is active. |
| | | 1 | The homing procedure of the ABR counter is completed. |
| 4 | StatusInput03 | 0 or 1 | Input state - Digital input 3 |
| 5 | StatusInput04 | 0 or 1 | Input state - Digital input 4 |
| 6 - 7 | Reserved | 0 | |

Error acknowledgment

Name:

ClearError01

This register can be used to acknowledge errors that have occurred on the motor.

For more info, see ["Error status" on page 2671](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|--------------------------------|
| 0 - 4 | Reserved | 0 | |
| 5 | ClearError01 | 0 | No effect |
| | | 1 | Error acknowledgment for motor |
| 6 - 7 | Reserved | 0 | |

Motor1Step0

Name:

Motor1Step0

This registers is used to specify the number and direction of steps that should be carried out by the module during the next X2X cycle.

The value is specified with a resolution of 1/256 of a full step (corresponds to 8-bit microsteps).

The direction of movement is derived from the value's sign:

| Data type | Values | Information |
|-----------|--------|--|
| INT | >0 | Movement in the positive direction in 1/256 full steps |
| | <0 | Movement in the negative direction in 1/256 full steps |

Unlike function model "Standard" without enabled SDC information, the motor current is selected using a separate register (see register ["Motor current" on page 2677](#)).

Home position

Name:

RefPulsePos01

These 2 registers have the following contents:

| Register | Description |
|--|--|
| Home position of the internal position counter | This register contains the home position of the internal position counter. |
| Home position for the ABR counter | This register contains the home position of the ABR counter. |

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Setting "Position sync" in the Automation Studio I/O configuration can be used to select which of the 2 registers is addressed by variable RefPulsePos01.

| Variables in Automation Studio | I/O configuration, counter 01, option "Position sync" | |
|--|---|---|
| | Stepper counter 01 is indicated on ActPos01 . | ABR counter 01 is indicated on ActPos01 . |
| RefPulsePos01 | Home position of the internal position counter | Home position of the ABR counter |
| Option "Position sync" for counter 1 also sets bit 3 in register " Counter configuration " on page 2667: | | |
| Bit 3 (counter 1) | 0 | 1 |

Reference pulse counter

Name:

RefPulseCnt01

These 2 registers have the following contents:

| Register | Description |
|---|---|
| Reference pulse counter for the internal position counter | The reference pulses of the internal position counter are counted in this register. |
| Reference pulse counter for the ABR counter | The reference pulses of the ABR counter are counted in this register. |

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Setting "Position sync" in the Automation Studio I/O configuration can be used to select which of 2 registers is addressed by variable RefPulsePos01.

| Variables in Automation Studio | I/O configuration, counter 01, option "Position sync" | |
|--|---|---|
| | Stepper counter 01 is indicated on ActPos01 . | ABR counter 01 is indicated on ActPos01 . |
| RefPulseCnt01 | Reference pulse counter for the internal position counter | Reference pulse counter of the ABR counter |
| Option "Position sync" for counter 1 also sets bit 3 in register " Counter configuration " on page 2667: | | |
| Bit 3 (counter 1) | 0 | 1 |

NetTime of the position value

Name:

ActTime01

This register contains the NetTime of the most recent valid position value.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Trigger counter

Name:

TriggerCnt01

This register contains a cyclic counter that is incremented with each trigger event.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Trigger timestamp

Name:

TriggerTime01

This register contains the NetTime instant of the most recent trigger event. The trigger edge must be configured in register "[SDC configuration](#)" on page 2676.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

Information:

The absolute accuracy of the trigger can be delayed up to 5 µs due to the input filter of the digital inputs.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.8.15.9 Register description: Function model 254 - "Bus controller" and function model 3 - "Ramp"

9.25.8.15.9.1 Configuration registers

Holding current, nominal current and maximum current

Name:

ConfigOutput03a (holding current)

ConfigOutput04a (nominal current)

ConfigOutput05a (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

| Register | Description |
|-----------------|---|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases. In the mode " Referencing during stall ", the rated current is always used instead of the maximum current, even in acceleration phases. |
| Holding current | Current when motor is at standstill |

When the current changes to a weaker value (e.g. when transitioning from the acceleration phase to the constant speed mode), the stronger current is maintained for an additional 100 ms. The following priority applies regardless of the values actually set: maximum current before nominal current before holding current.

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 120 | Percent of the module's rated current <ul style="list-style-type: none"> • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 120% corresponds to the maximum current of the motor bridge power unit listed in the technical data. Bus controller default setting: 0 |

Full step threshold

Name:

FullStepThreshold01

Starting with the speed specified in this register, the motor is operated in full step mode; it is operated in microstep mode below it.

| Data type | Values | Information |
|-----------|------------|---|
| UINT | 1 to 65534 | Speed in microsteps/cycle. Bus controller default setting: 0 |
| | 65535 | Motor is always operated in microstep mode |

Maximum speed

Name:
MaxSpeed01pos

This register defines the maximum speed for the absolute positioning modes (1, -123, -124, -125, -126).

Information:

The setting does not apply to the speed and homing modes (2, -127, -128).

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Speed in microsteps/cycle. Bus controller default setting: 0 |

Maximum acceleration

Name:
MaxAcc01

This register defines the maximum acceleration. (also applies for homing modes).

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Acceleration in microsteps/cycle ² . Bus controller default setting: 0 |

Maximum deceleration

Name:
MaxDec01

This register defines the maximum deceleration. (also applies for homing modes).

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Brake deceleration in microsteps/cycle ² . Bus controller default setting: 0 |

Reversing loop

Name:
RevLoop01

This parameter is only used in modes 1, -123, -124, -125, -126 (absolute positioning modes).

If the value for the reversing loop is not equal to 0, the target position is approached directly when coming from one direction; when coming from the other direction, the target position is initially overshoot by the configured number of steps before finally moving to the target position. This ensures that the target position is always approached from the same direction (to avoid mechanical backlash).

The sign of the defined value determines the direction in which the reversing loop runs.

| Sign | Effective direction |
|----------|--|
| Positive | Reversing loop in positive direction of movement |
| Negative | Reversing loop in negative direction of movement |

| Data type | Values | Information |
|-----------|-----------------|-----------------------------------|
| INT | -32768 to 32767 | Bus controller default setting: 0 |

Fixed position A

Name:
FixedPos01a

This register defines the position to move to in modes -124 (if the digital input is set to 1) and -125.

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Fixed position B

Name:
FixedPos01b

This register defines the position to move to in modes [-124](#) (if the digital input is set to 0) and [-126](#).

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Homing speed

Name:
RefSpeed01

This register sets the speed for homing modes [-127](#) and [-128](#).

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Speed in microsteps/cycle. Bus controller default setting: 0 |

Stall recognition delay

Name:
StallRecognitionDelay01

The value in this register is only relevant for [Referencing during stall](#).

A stall is only detected after the time specified here has expired and after the homing procedure has started.

For example, a setting of 4 (and a cycle time of 25 ms) means that a stall will not be detected until 100 ms after the motor starts moving (start of the homing procedure).

Set to 0 to eliminate delay.

| Data type | Values | Information |
|-----------|----------|---|
| USINT | 0 to 255 | In cycles, see " General configuration " on page 2684. Bus controller default setting: 0 |

Minimum speed for stall detection

Name:
StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled and the configured [mixed decay threshold](#) is used. The value 15 is always used for the mixed decay threshold below this threshold value, and no stall error is reported. This means that mixed decay mode is always enabled at low speeds where stall detection principally does not work.

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Minimum speed in microsteps per cycle. Bus controller default setting: 0 |

Jerk time

Name:
JoltTime01

If a value other than 0 is assigned to this register, then jerk limitation is performed. This is done by averaging the values for the steps to be carried out (speed setpoint) in each cycle using a FIFO buffer. The jerk time corresponds to the number of FIFO elements (0 to 80). If a value greater than 80 is entered, then it will be limited internally to 80.

Changes made while a motor is running will be applied as soon as ...

- The motor has reached the set position (positioning mode only).
- The motor has stopped (all modes).

| Data type | Values | Information |
|-----------|-----------------------|---|
| USINT | 0 | No jerk limitation time. Bus controller default setting: 0 |
| | 1 to 80 ¹⁾ | Number of FIFO elements |

1) Starting with upgrade 1.3.1.0 (firmware version 16), for older versions: 16

Homing configuration

Name:
RefConfig01

The homing mode can be set with this register.

| Data type | Values | Information |
|-----------|------------|--|
| USINT | -120 | Set home position |
| | -121 | Homing on positive edge of input DI 4 |
| | -122 | Homing on falling edge of input DI 4 |
| | -125 | Homing on positive edge of input DI 3 (R pulse). Bus controller default setting |
| | -126 | Homing on negative edge of input DI 3 (R pulse) |
| | -127 | Homing during stall detection |
| | -128 | Immediate homing |
| | All others | No effect |

Stall detection configuration / Mixed decay

Name:
StallDetectConfig01

The mixed decay threshold and stall detection sensitivity can be configured in this register.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------|---------|---|
| 0 - 3 | Mixed decay threshold | 0 | Mixed decay disabled (bus controller default setting) |
| | | 1 to 14 | Setting for mixed decay threshold |
| | | 15 | Mixed decay always enabled |
| 4 - 6 | Stall threshold | 0 | Stall detection is disabled (bus controller default setting) |
| | | 1 to 6 | Steps involved in setting stall detection sensitivity |
| | | 7 | Maximum sensitivity for stall detection |
| 7 | Motor load | 0 | Motor load value not shown (bus controller default setting) |
| | | 1 | Show value in register "Status word" on page 2692 ¹⁾ |

1) If this bit is 1, then the motor load value is shown in bits 13 to 15 of the status word register (otherwise these bits are 0). This value can help when testing the stall detection and the [Home during stall](#) mode.

Stall threshold

The SM module features integrated sensorless load measurement for the motor axis. This is especially useful for detecting a "stall condition" (e.g. if the motor moves to the end point during a homing procedure). It cannot be used for torque monitoring during dynamic movements.

The "stall threshold" (bits 4 to 6 of this register) can be used to define a threshold value for each axis individually according to the motor load, beyond which the motor will detect a stall condition.

This threshold value must be determined on a case-by-case basis, since the results of load measurement are influenced by a variety of factors.

- Motor speed: A higher speed results in higher measurement values
- Speeds that cause motor resonances (which interfere with load measurement) are to be avoided
- Motor accelerations that create a dynamic load (and also affect the measurement) should also be avoided
- It is especially important to be aware that mixed decay mode must be optimized for reliable stall detection.

The higher the load measurement value, the lower the load. This means that a stall condition is detected if the load measurement value drops below the trigger threshold for stall detection.

Mixed decay threshold

Mixed decay modules provide a greatly optimized sinusoidal current profile in the individual phases of the stepper motor, especially for fast current changes and low current values.

Mixed decay interferes with reliable stall detection, however. For this reason, mixed decay mode can be disabled during stall detection (motor load measurement) using the mixed decay threshold. The smaller the configured mixed decay threshold, the larger the range in which mixed decay is disabled while motor load measurement takes place.

Mixed decay mode is always enabled if the mixed decay threshold is set to 15.

Relationship between stall detection and mixed decay

Depending on the application and the motor used, satisfactorily smooth operation can be achieved while using stall detection by setting the mixed decay threshold to a value between 1 and 14. This is a compromise between smooth operation and stall detection quality and must be fine tuned during commissioning.

General configuration

Name:

GeneralConfig01

Bit 0 of this register can be used to switch the positioning mode. This register can also be used to configure the cycle time of the motion profile generator.

- 0: "Mode 1: Position mode" without extended control word
- 1: "Mode 1: Position mode with extended control word"

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|--|
| 0 | Position mode | 0 | Without extended control word (bus controller default setting) |
| | | 1 | With extended control word |
| 1 - 2 | Cycle time of the motion profile generator ¹⁾ | 00 | 25 ms (bus controller default setting) |
| | | 01 | 10 ms |
| | | 10 | 5 ms |
| | | 11 | Reserved |
| 3 - 7 | Reserved | 0 | |

1) This parameter is supported starting with upgrade 1.3.1.0 (firmware version 16).

The cycle time for the motion profile generator is configured with this cycle. This cycle time affects the unit for specifying the speed and acceleration:

- Unit for speed: Microsteps/Cycle
- Unit for acceleration: Microsteps/Cycle²

Limit switch configuration

Name:

LimitSwitchConfig01

This register configures the behavior of the limit switches.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------|-------|---|
| 0 - 1 | Negative limit switch | 00 | Switched off (bus controller default setting) |
| | | 01 | Active if low |
| | | 10 | Reserved |
| | | 11 | Active if high |
| 2 - 3 | Positive limit switch | 00 | Switched off (bus controller default setting) |
| | | 01 | Active if low |
| | | 10 | Reserved |
| | | 11 | Active if high |
| 4 - 6 | Reserved | 0 | |
| 7 | Direction monitoring | 0 | Off (bus controller default setting) |
| | | 1 | On |

Negative/Positive limit switch:

When one of the limit switches is reached, a warning is triggered and the speed is decelerated to 0. There is no state change of "Device control state machine". This keeps current flowing to the motor.

The error that occurred can be read from the error code register. Normal operation can be resumed by acknowledging the warning. This will not restrict motor movement to a specific direction and the limit switch will not be triggered until the next active edge.

Overshooting the limit switch while braking

The limit switches are not linked with the corresponding direction of movement. If the limit switch is exceeded, another error will be triggered when reversing after acknowledging the initial error.

Direction monitoring

If this function is enabled, then the two limit switches will be linked with the respective direction of movement. This means that the negative limit switch is only triggered in the negative and the positive limit switch only in the positive direction of movement (specified direction).

This prevents specifying a movement in the wrong direction when direction monitoring is enabled and limit switches are active.

Warning!

If the motor is wired incorrectly with this configuration (wrong direction of movement), then the limit switch will not be triggered and the actual correct direction of movement will be denied. This will also be the case when the limit switch connections are reversed.

Software limit

Name:

PositionLimitMin01

PositionLimitMax01

This register configures software limits. The function is enabled if at least one of the two registers is not equal to zero.

These limits are effective in all positioning modes. Position overflow is not possible when this function is enabled. Movement is always contained within the two limits.

If a position is specified that violates the minimum/maximum software limit, the "Internal limit active" bit will be set in the "Status word" on page 2692 register. The motor movement will be stopped until a position is specified within the limits.

Bit "Internal limit active" will also be set in register "Status word" if incorrectly configured (minimum > maximum).

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Information:

The software limits will only be monitored when using the following CANopen bus controllers:

- X20BC0043-10
- X20BC0143-10
- X67BC4321-10
- X67BC4321.L08-10
- X67BC4321.L12-10

9.25.8.15.9.2 Reading back the configuration

Reading back the holding current, nominal current and maximum current

ConfigOutput03aRead (holding current)

ConfigOutput04aRead (nominal current)

ConfigOutput05aRead (maximum current)

These registers are used to read the respective current values in percent.

| Register | Description |
|-----------------|--|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases |
| Holding current | Current when motor is at standstill |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 255 | Percentage of module's nominal current (100% corresponds to the nominal current of the motor bridge power unit in the technical data) |

9.25.8.15.9.3 Communication registers

Set position/speed

Name:

AbsPos01

This register is used to set position or speed, depending on the operating mode.

- Position mode (see "Mode" on page 2687): Cyclic setting of the position setpoint in microsteps. In this mode, one micro-step is always 1/256 full-step.
- Speed mode (see "Mode" on page 2687): In this mode, this register is considered a signed speed setpoint.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Control word

Name:

MpGenControl01

This register can be used to issue commands based on the module's state (see ["Operating function model "Ramp" on page 2695](#)).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|------------------------|-------|--|
| 0 | Switch on | x | |
| 1 | Enable voltage | x | |
| 2 | Quick stop | x | |
| 3 | Enable operation | x | |
| 4 - 6 | Mode-specific | x | |
| 7 | Fault reset | x | |
| 8 | Stop ¹⁾ | x | |
| 9 - 10 | Reserved | 0 | |
| 11 | Motor ID trigger | 0 | No effect |
| | | 1 | Rising edge: Motor ID trigger ²⁾ |
| 12 | Warning reset | 0 | No effect |
| | | 1 | Rising edge: Reset warnings |
| 13 | Undercurrent detection | 0 | Disable current error detection (default) |
| | | 1 | Enable current error detection |
| 14 | ABR counter sync/async | 0 | Default: <ul style="list-style-type: none"> Internal position counter, cyclic ABR counter, acyclic |
| | | 1 | <ul style="list-style-type: none"> Internal position counter, acyclic ABR counter, cyclic |
| 15 | Stall detection | 0 | Disable stall detection (default) |
| | | 1 | Enable stall detection |

1) The "Stop" bit is only evaluated when the extended control word is enabled (see ["General configuration" on page 2684](#)).

2) This bit can be used to trigger a measurement of the motor ID. Keep in mind that the application must ensure that the conditions for measurement are fulfilled (see table in the ["Motor identification" on page 2693](#) register).

Mode

Name:

MpGenMode01

| Data type | Values | Information |
|-----------|--------|---|
| SINT | 0 | No mode selected |
| | 1 | Depending on bit 0 in the "General configuration" on page 2684 register, the position mode will behave as follows: <ul style="list-style-type: none"> Position mode without extended control word: Move to target position as soon as the target position is changed Position mode with extended control word: Move to the target position as described in "Mode 1 - Position mode with extended control word" on page 2688 |
| | 2 | Speed mode: Constant speed |
| | -120 | Set home position |
| | -121 | Remaining distance mode |
| | -122 | Set actual position |
| | -123 | Move to target position when external input set |
| | -124 | Two-position module |
| | -125 | Move to fixed position A (position set acyclically) |
| | -126 | Move to fixed position B (position set acyclically) |
| | -127 | Positive homing (see also "Homing configuration" on page 2683) |
| | -128 | Negative homing (see also "Homing configuration" on page 2683) |

Information:

For all modes: The "Target reached" bit is set in the ["Status word" on page 2692](#) register when the current action is finished (i.e. when the position or speed is reached, depending on the mode).

A new position or speed can be specified even before the current action is finished.

Mode 1 - Position mode

The position setpoint is specified in the "Set position/speed" on page 2686 register. The motor is then moved to this new position. This is done with a ramp function that accounts for the defined maximum speed and acceleration values.

The position setpoint can also be changed during an active positioning procedure.

The position setpoint is specified in microsteps (1/256 of a full step).

If bit 0 in the "General configuration" on page 2684 register is 0 (no extended control word), then the position setpoint will be applied as soon as it is different from the current position. Then the new position is used for the movement.

However, if bit 0 in the "General configuration" on page 2684 register is set to 1 (extended control word), then the position setpoint will be applied as described under "Mode 1 - Position mode with extended control word" on page 2688.

Mode 1 - Position mode with extended control word

Position mode with extended control word behaves like Position mode 1 as described previously (without the extended control word), but the new position setpoint ("Position/Speed" on page 2686 register) is applied according to the extended control word.

Extended control word

Commands can be issued using this register depending on the state of the module (see "Operating function model "Ramp"" on page 2695).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|---|
| 0 - 3 | Corresponds to the default Control word | x | |
| 4 | New setpoint | 0 | Do not apply target position. |
| | | 1 | Apply target position. |
| 5 | Change set immediately | 0 | Complete current positioning movement and then start next positioning movement |
| | | 1 | Interrupt current positioning movement and then start next positioning movement |
| 6 | abs / rel | 0 | Target position is an absolute value. |
| | | 1 | Target position is a relative value. |
| 7 | Corresponds to the default Control word | x | |
| 8 | Stop ¹⁾ | 0 | Execute positioning |
| | | 1 | Stop axis with deceleration |
| 9 - 15 | Corresponds to the default Control word | x | |

1) This bit applies to all modes.

Extended status word

The bits in the status word reflect the status of the state machine (for a detailed description, see "Status word" on page 2696 and "State machine" on page 2697).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|-------|---|
| 0 - 9 | Corresponds to the default Status word | x | |
| 10 | Target reached, depending on bit 8 (Stop) in the Control word register | | If Stop = 0 |
| | | 0 | Target position not reached. |
| | | 1 | Target position reached |
| | | | If Stop = 1 |
| | | 0 | Axis decelerating |
| 11 | Corresponds to the default Status word | x | |
| | | | |
| 12 | Setpoint acknowledge | 0 | Ramp generator did not apply the position value |
| | | 1 | Ramp generator applied the position value |
| 13 - 15 | Corresponds to the default Status word | x | |

Position setting

The target position can be defined in 2 different ways:

| Type of setpoint definition | Description |
|-----------------------------|---|
| Single setpoint | After the target position is reached, Bit <i>Target reached</i> in register "Status word" on page 2692 is set. Then a new target position is defined. The drive stops at each target position before starting the movement to the next target position. |
| Set of setpoints | After the target position has been reached, the movement to the next target position is started immediately without stopping the drive. It is therefore possible to initiate a new positioning by specifying another target position during active positioning. |

The two modes "Single setpoint" and "Set of setpoints" are controlled by the timing of bits *New setpoint* and *Change set immediately* in the "extended control word" on page 2688 and *Setpoint acknowledge* in register "Extended control word" on page 2688.

These bits can be used to create a Request-Response mechanism. This makes it possible to specify a target position while a previous position specification is still being processed.

Specifying the target position

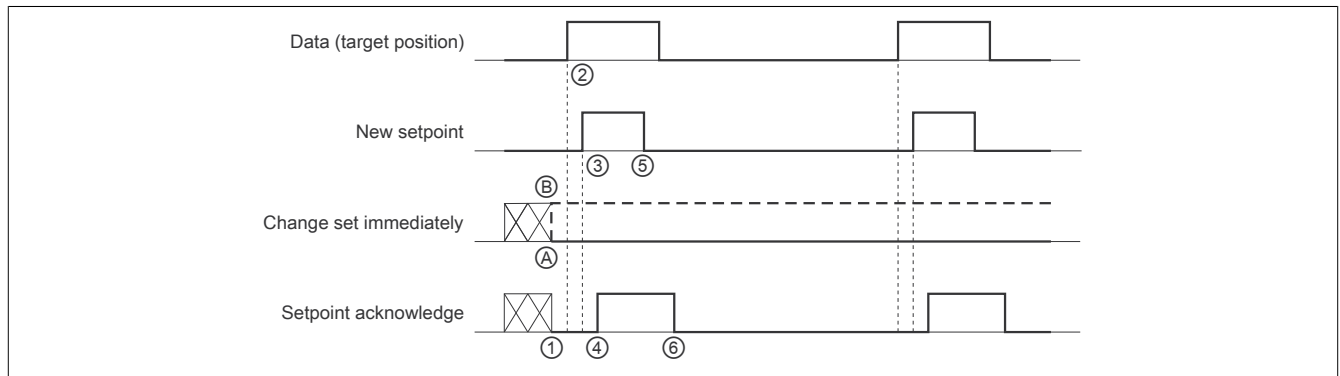

Figure 184: Principle for applying the setpoint

Transferring a new setpoint:

- 1) If bit *Setpoint acknowledge* in register "Extended status word" on page 2688 is 0, the module will accept a new target position.
- 2) The new target position is specified in register "Set position/speed" on page 2686.
- 3) A rising edge on bit *New setpoint* in the "extended control word" on page 2688 indicates that the new target position in register "Set position/speed" on page 2686 is valid and can be used for the next positioning movement.
- 4) After the module has received and saved the new target position, bit *Setpoint acknowledge* is set to 1 in register *Status word*.
- 5) Now the controller can reset the *New setpoint* bit to 0.
- 6) Then the module resets bit *Setpoint acknowledge* to 0 to signal when a new target position is accepted.

Position specification "Single setpoint"

When the *Change set immediately* bit is set to 0 (A in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This mechanism results in a speed of 0 when the motor reaches target position x_1 at time t_1 . After the controller has been notified that the setpoint has been reached, the next target position x_2 will be processed at time t_2 and reached at t_3 .

Figure 185: Ramp in *Single setpoint*

"Set of setpoints" preset position value

When the *Change set immediately* bit is set to 1 (Ⓢ in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This means that the module receives the first target position at t_0 . A second target position is received at time t_1 . The drive immediately adapts the current movement to the new target position.

Figure 186: Ramp in *Set of setpoints*

Relative position setting

If bit *abs / rel* in register *Extended control word* is set, then the target position is interpreted as a relative value. At each *New setpoint* trigger, the target position will be increased by this value (or decreased if the value is negative).

If the mode changes between the position settings, relative movement will then proceed starting at the last specified position. The position setpoint mode is initialized with 0 when the module is started.

Mode 2: Speed mode - Constant speed (pos./neg.)

The value in register "*Position/Speed*" on page 2686 is now interpreted as the speed setpoint (microsteps/ cycle).

Observing the maximum permissible acceleration, the motor moves with a ramp to the desired speed setpoint and maintains this speed until a new speed setpoint is specified.

Values are allowed within the range -65535 to 65535. When a value is entered outside of this range, it is readjusted to these limits.

Mode -120: Set home position

This mode is supported starting with upgrade 1.3.1.0 (firmware version 16).

The current actual position is changed so that the position specified in register "*Position/Speed*" on page 2686 is the home position. If you then move to this position, the motor is at the home position.

The home position in register "*Home position*" on page 2693 is also set to this value.

Before this mode is called, the motor must be at a standstill and the home position must have been determined using "*Positive / negative homing*" mode. In order to set the position, the *State machine* must be in state "Operation enable".

Mode -121: Remaining distance mode (like mode 1)

The number of steps defined in register "*Fixed position A*" on page 2681 are added to the current position and the resulting position is approached at a rising/falling edge on digital input 3.

Advice:

Steps are not added to the target position, but rather to the current position at the moment the trigger occurs.

Negative values are also allowed for the offset defined in *Fixed position A*.

New target positions are no longer accepted in register "*Position/Speed*" on page 2686 after the trigger event. There must first be a switch made to *mode 0* and then back to mode -121.

Bit "Target reached" in register "*Status word*" on page 2692 is not set to 1 until the end position (after the trigger event) has been reached.

The "*homing configuration*" on page 2683 determines whether a rising or falling edge of the digital input is used as a trigger.

The *Reversing loop* is not enabled in this mode (i.e. any configured values not equal to 0 are ignored).

Mode -122: Set actual position

The target position set in register "[Position/Speed](#)" on page 2686 is applied as the current actual position in the internal position counter if the state machine is in state "Operation enable".

Before this mode is started, the motor must be at a standstill and physically located at the point for which the position being set should be applied.

Mode -123: Move to the target position when the external input is set

The position setpoint set in register "[Position/Speed](#)" on page 2686 is moved on a rising edge of digital input 3.

A new position setpoint is not applied until another rising edge occurs on the corresponding digital input. This can also occur during the active positioning procedure and will be applied immediately.

Mode -124: Two-position mode

Positions [Fixed position A](#) and [Fixed position B](#) are defined in the acyclic registers.

Value 1 on digital input 3 moves to fixed position A. Value 0 moves to fixed position B. It is also possible to switch between the two during an active positioning movement.

Mode -125/-126: Move to fixed position X

The purpose of these modes is to enable a virtual switch from speed mode to position mode, which otherwise is not possible because of the shared use of the register for position and speed setpoints.

- Mode -125: "[Fixed position A](#)" on page 2681
- Mode -126: "[Fixed position B](#)" on page 2682

Mode -127/-128: Positive/Negative homing

Mode -127 and -128 are used to select which direction to move.

The motor must be at a standstill before switching from another mode to one of the homing modes.

If the referencing condition occurs, then the motor stops and the values of the position counter and ABR counter valid at the moment when the referencing condition occurs are written to the "[Referenced zero position](#)" on page 2693 register.

In the [referencing configuration](#) you must specify whether referencing should occur at low/high level on the digital input, during stall or unconditionally.

Homing via digital input

Case 1: Active referencing level not yet reached → Motor not yet at end position:

Movement continues at the referencing speed in the referencing direction until the active level for "Stop referencing" is on the input.

Case 2: Active referencing level already reached → Motor at end position:

Movement continues at the referencing speed against the referencing direction until the active level for "Stop referencing" is no longer at the digital input. Movement continues at homing speed in the homing direction until the active level for "homing-stop" is on the digital input again.

Referencing during stall

Movement continues in the referencing direction until a stall is detected. When a stall is detected, the value of the position counter is entered in the "[Referenced zero position](#)" on page 2693 register within one millisecond. The motor is then stopped abruptly (not using the deceleration ramp). However, it can take up to 25 ms to stop the motor because the ramp generator runs with a configurable internal cycle of up to 25 ms.

In this mode, the nominal current is always used instead of the maximum current, even in acceleration phases.

To test the responsiveness of this homing mode, the motor load value used for identifying a stall can be made visible in the status word (see "[Stall detection configuration / Mixed decay](#)" on page 2683).

Unconditional referencing (immediate)

Immediate referencing: The current values of the position counter and of the ABR counter are immediately entered in register "[Homed zero position](#)" on page 2693, no motor movement.)

Current position (cyclic)

Name:

AbsPos01ActVal

This cyclic register contains the current position.

Default: Value of the internal position counter, can be changed to ABR counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Status word

Name:

MpGenStatus01

The bits in this register reflect the state of the state machine. For a more detailed description, see ["Status word" on page 2696](#) and ["State machine" on page 2697](#).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|-----------------------------|-------|---|
| 0 | Ready to switch on | x | |
| 1 | Switched on | x | |
| 2 | Operation enabled | x | |
| 3 | Fault (error bit) | x | |
| 4 | Voltage enabled | x | |
| 5 | Quick stop | x | |
| 6 | Switch on disabled | x | |
| 7 | Warning | x | |
| 8 | Reserved | 0 | |
| 9 | Remote | 1 | Always 1 since there is no local mode for the SM module |
| 10 | Target reached | x | |
| 11 | Internal limit active | 0 | No limit violation |
| | | 1 | Internal limit is active (upper or lower software limit violated) |
| 12 | Mode-specific | x | |
| 13 - 15 | Reserved / Motor load value | 0 | Always 0 if bit 7 in register "Stall detection configuration / Mixed decay" on page 2683 is set to 0. |
| | | x | Returned motor load value |

Input status

Name:

InputStatus

This register indicates the logical states of digital inputs.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|--------|-------------------------------|
| 0 | Digital input 1 | 0 or 1 | Input state - Digital input 1 |
| ... | | ... | |
| 3 | Digital input 4 | 0 or 1 | Input state - Digital input 4 |
| 4 - 7 | Reserved | 0 | |

Motor identification

Name:

Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. After successful measurement, this register contains the time [µs] required to apply a current increase of $\Delta I = 1 \text{ A}$ to a motor winding.

This depends on:

- Operating voltage
- Inductance and resistance of the motor winding

| Notes | |
|-------|---|
| 1) | To achieve reproducible results, the measurement must be made under the following defined conditions: |
| a) | Motor is at standstill. |
| b) | The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: <ul style="list-style-type: none"> • Full steps are divisible by 4. • Microsteps = 0 |
| 2) | Condition 1b) is fulfilled after a the SM module is reset or switched on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application. |
| 3) | The current range from approximately 1/3 of the nominal current up to the nominal current is used as operating range for determining the motor identifier. |

| Data type | Motor ID values | Explanation |
|-----------|-----------------|--|
| UINT | 0 | No motor identifier available (after switching on for as long as the measurement conditions are not met) |
| | 1 to 32767 | Valid range of values for the motor ID register (in µs) |
| | 65504 to 65519 | Ground fault: Measurement of motor identification not possible |
| | 65528 | Motor ID trigger not possible <ul style="list-style-type: none"> • Motor not supplied with current • Motor in movement • Nominal current set to 0 A • Ground fault present |
| | 65529 | Invalid value: Underflow |
| | 65530 | Overtemperature: Measurement not possible |
| | 65532 | Open circuit: Measurement not possible |
| | 65533 | Incorrect motor position: Measurement not possible |
| | 65534 | Invalid value: Overflow |
| | 65535 | Measurement in progress |

Ground fault detection

When the motor is powered on, a ground fault check is performed before motor identification. Error numbers have been added in the motor identification register for the event of a ground fault error (values 65504 to 65519 in the table above).

Homed zero position

Name:

RefPos01CyclicCounter

RefPos01AcyclicCounter

After a homing procedure, the homing point for the cyclic or acyclic position counter can be read back with these registers (either the internal position counter or ABR counter depending on bit 14 of register "Control word" on [page 2687](#)).

The following two registers are provided for the motor:

- Homed zero position for cyclic counter
- Homed zero position for acyclic counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Current position (acyclic)

Name:

AbsPos1ActValAcyclic

This acyclic register contains the current position.

Default: Value of the ABR counter, can be changed to internal position counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Read back control word

Name:

ControlReadback01

This register can be used to read the contents of register "Control word" on page 2687.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Read back mode

Name:

ModeReadback01

This register can be used to read the contents of register "Mode" on page 2687.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Error code

Name:

ErrorCode01

The cause of an error or warning can be read in this register.

| Data type | Error code | Error type | Priority | Description |
|-----------|------------|------------|----------|-----------------------------|
| UINT | 0x0000 | - | - | No error |
| | 0x3000 | Error | High | Voltage |
| | 0x4200 | Error | : | Overtemperature |
| | 0xFF20 | Warning | : | Negative limit switch |
| | 0xFF21 | Warning | : | Positive limit switch |
| | 0x2300 | Warning | : | Overcurrent |
| | 0xFF00 | Warning | : | Current error ¹⁾ |
| | 0xFF01 | Warning | low | Stall ²⁾ |

1) A current error is only detected if bit 13 = 1 in the [control word](#) (current error detection enabled).2) Stall is only detected if bit 15 = 1 in the [control word](#) (stall detection enabled).

Information regarding the handling of errors and warnings:

- Bit 3 (fault) and bit 8 (warning) in the [status word](#) can be used to query whether an error or a warning was reported in the error code register.
- Bit 7 (Fault Reset) and bit 8 (Warning Reset) in the [control word](#) are used to acknowledge pending errors and warnings.
- If two or more errors/warnings are pending, the one with the highest priority (the order in the table above) will be displayed in the error code register.

9.25.8.15.9.4 Operating function model "Ramp"

Control for this model has been based on the CANopen communication profile DS402.

Commands for controlling the modules are written to the "Control word" on page 2695. The current module state is returned in register "Status word" on page 2696. The function mode (absolute position, constant speed, homing, etc.) is set in register "Mode" on page 2687.

Control word

Control word bits and their state for the commands of the state machine:

| Command | Reserved | Encoder position sync/async | Current error detection | Warning reset | Motor ID trigger | Reserved | Reserved | Stop 2) | Fault reset | Mode-specific | Mode-specific | Mode-specific | Enable operation | Quick stop | Enable voltage | Switch on |
|-------------------|----------|-----------------------------|-------------------------|---------------|------------------|----------|----------|---------|-------------|---------------|---------------|---------------|------------------|------------|----------------|-----------|
| Bit ¹⁾ | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Shutdown | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 1 | 1 | 0 |
| Switch on | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | 0 | 1 | 1 | 1 |
| Disable voltage | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | x | 0 | x |
| Quick stop | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 0 | 1 | x |
| Disable operation | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 0 | 1 | 1 |
| Enable operation | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | 1 | 1 | 1 | 1 |
| Fault reset | x | x | x | x | x | 0 | 0 | x | ↑ | x | x | x | x | x | x | x |

1) x ... Any, ↑ ... Rising edge

2) Bit 8 (stop) is only evaluated if the extended control word is enabled in register "General configuration" on page 2684.

| | |
|---|--|
| Bits 0, 1, 2, 3 and 7 (light gray in the previous table) | These bits control the state of the State machine according to the commands in the table above. |
| Stop | 0 ... Perform motor movement 1 ... Stop axis with deceleration This bit is only evaluated when the extended control word is enabled in register "General configuration" on page 2684. |
| Motor ID trigger | A rising edge enables the motor ID measurement. |
| Warning reset | A rising edge resets warnings (no effect on errors, which are reset using "Fault reset"; the state machine is not affected by this bit). |
| Fault reset | A rising edge resets errors and warnings (see "State machine" on page 2697) |
| Current error detection | 0 ... Current error detection disabled 1 ... Current error detection enabled |
| ABR counter sync/async | 0 ... Value of the ABR counter on register "Current position (acyclic)" on page 2694. Internal position counter of the ramp generator on register "Current position (cyclic)". 1 ... Value of the ABR counter on register "Current position (cyclic)" on page 2692. Internal position counter of the ramp generator on register "Current position (acyclic)". |
| Stall detection | 0 ... Stall detection disabled 1 ... Stall detection enabled |
| CurrentControlEnable | 0 ... Load-dependent current control disabled 1 ... Load-dependent current control enabled |

Status word

The individual bits of this register and its states depend on the current state of the state machine:

| Status | Reserved / MotorLoadBit 2 ¹⁾ | Reserved / MotorLoadBit 1 ¹⁾ | Reserved / MotorLoadBit 0 ¹⁾ | Reserved | Int. limit active | Target reached | Remote | Reserved | Warning | Switch on disabled | Quick stop | Voltage enabled | Fault | Operation enabled | Switched on | Ready to switch on |
|------------------------|---|---|---|----------|-------------------|----------------|--------|----------|---------|--------------------|------------|-----------------|-------|-------------------|-------------|--------------------|
| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Not ready to switch on | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 0 | 0 | 0 | 0 |
| Switch-on disabled | x | x | x | x | x | x | 1 | 0 | x | 1 | x | 0 | 0 | 0 | 0 | 0 |
| Ready to switch on | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 0 | 0 | 0 | 0 | 1 |
| Switched on | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 1 | 0 | 0 | 1 | 1 |
| Operation enable | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 1 | 0 | 1 | 1 | 1 |
| Quick stop active | x | x | x | x | x | x | 1 | 0 | x | 0 | 0 | 1 | 0 | 1 | 1 | 1 |
| Fault reaction active | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 1 | 1 | 1 | 1 |
| Fault | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 1 | 0 | 0 | 0 |

- 1) If bit 7 is set to 1 in register "Mixed Decay / Stall Detection" on page 2683, then the motor load value is returned in bits 13-15 of the status word. Otherwise, these bits are always 0.

Information about the status word:

| | | |
|---|--|--|
| Bits 0, 1, 2, 3, 5 and 6 (light gray in the previous table) | These bits are set according to the current state of the State machine . | |
| Voltage enabled | Becomes 1 as soon as the motor is powered | |
| Warning | Becomes 1 if a warning is detected ("Overcurrent", "Undercurrent"). The type of warning is indicated in register "Error code" on page 2694. The highest priority error / warning is shown in each case, with the priority corresponding to the order in the respective table. Warnings can be reset with a rising edge on the "Warning reset" bit in the control word. | |
| Remote | Always 1 since there is no local mode on the SM module | |
| Target reached ¹⁾ , depending on bit 8 (Stop) in register Control word | <p>If Stop = 0</p> <p>In modes 1, -123, -124, -125 and -126 (absolute positioning): 0...Positioning begins 1...Target has been reached</p> <p>In mode 2 (constant speed): 0...Motor accelerates/brakes 1...Speed setpoint reached</p> <p>In modes -127 and -128 (homing): 0...Homing started 1...Homing ended</p> <p>In mode -122 (set actual position): The bit briefly becomes 0 and immediately becomes 1 again as soon as the position is set.</p> | <p>If Stop = 1</p> <p>In all modes: 0...Axis decelerating 1...Axis speed = 0</p> |
| Internal limit active | 0 ... No limit violation 1 ... Internal limit is active (upper/lower software limit violated) | |

- 1) If "Stop" has not been enabled in register "General configuration" on page 2684, then "Target reached" behaves the same as if Stop = 0.

State machine

The motor is controlled according to the state machine illustrated below. After the module is started, the state machine automatically changes to state "Not ready to switch on". The application then operates the state machine by writing commands to the [Control word](#).

The state machine successively reaches the states "Ready to switch on", "Switched on" and "Operation enable" by writing the consecutive commands "Shutdown", "Switch on" and "Enable operation".

Information:

Only in state "Operation enable" are motor movements executed according to the setting in register "Mode" on page 2687.

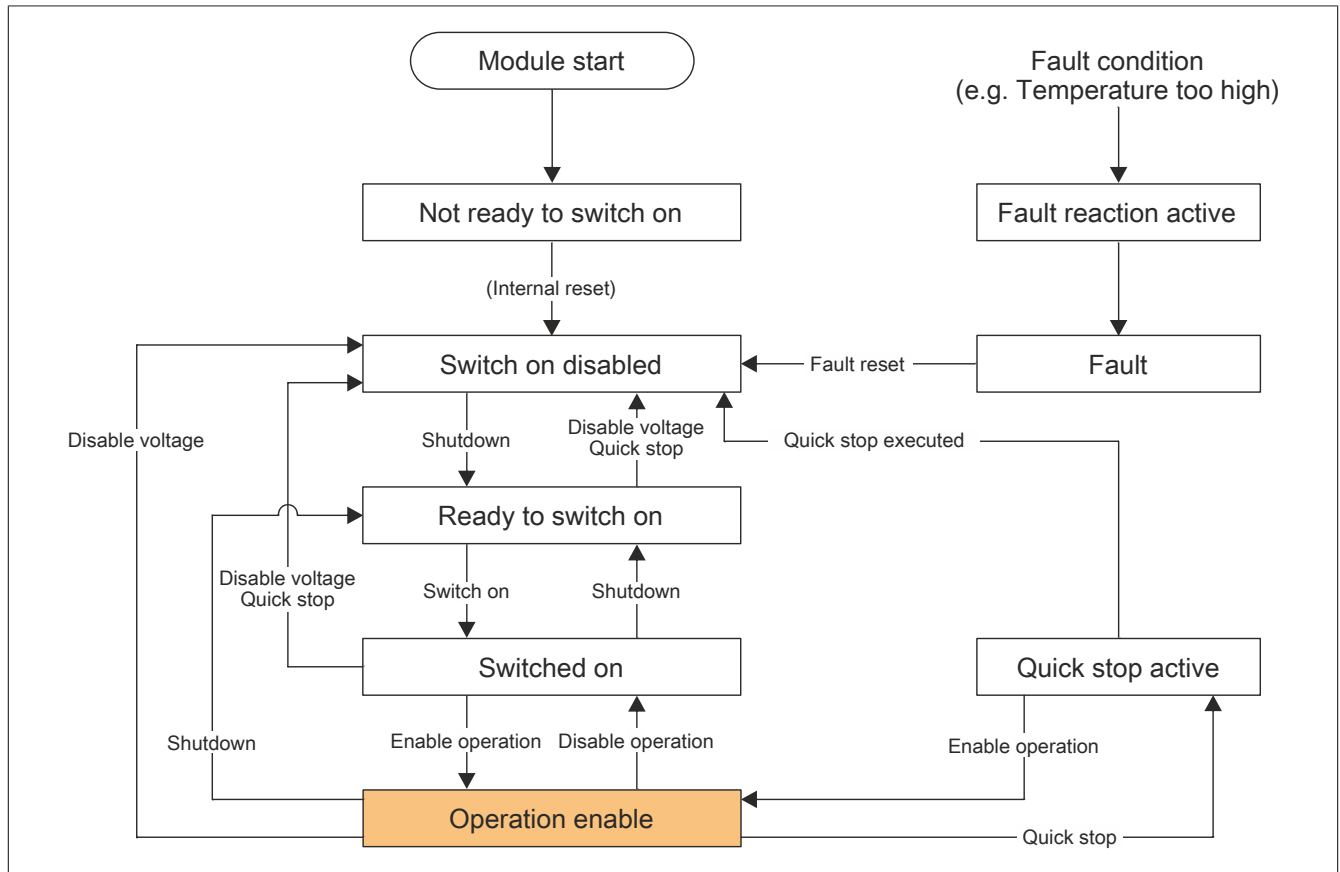

Figure 187: State machine - Flow chart

| State change | Description |
|--|--|
| Not ready to switch on → Switch on disabled | This state change occurs automatically after starting the module and internal initialization has taken place. |
| Switch-on disabled → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . No others actions are performed. |
| Ready to switch on → Switch-on disabled | This state change is brought on by the command <i>Disable voltage</i> or <i>Quick stop</i> . No others actions are performed. |
| Switched on → Switch-on disabled | This state change is brought on by the command <i>Disable voltage</i> or <i>Quick stop</i> . The motor voltage is cut off immediately. |
| Ready to switch on → Switched on | This state change is brought on by the <i>Switch on</i> command. The motor voltage is switched on. When this state change occurs for the first time since the module is started, the motor ID measurement is performed before state <i>Switched on</i> is achieved. This can take approximately 1 second. |
| Switched on → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . The motor voltage is cut off immediately. |
| Switched on → Operation enable | This state change is brought on by the <i>Enable operation</i> command. Motor movements are now performed depending on the set mode. |
| Operation enable → Switched on | This state change is brought on by the <i>Disable operation</i> command. If in motion, the motor is decelerated with the configured braking deceleration. The motor voltage remains switched on in state <i>Switched on</i> . |
| Operation enable → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . The motor voltage is cut off immediately. |
| Operation enable → Switch on disabled | This state change is brought on by the <i>Disable voltage</i> command. Motor voltage switched off. It is strongly recommended to only make this state change on a stopped motor since regeneration on a motor running at no load can cause an overvoltage error on the DC bus (0x3210). |
| Operation enable → Quick stop active | This state change is brought on by the <i>Quick stop</i> command. If in motion, the motor is decelerated with the configured braking deceleration. During the deceleration, the state machine remains in state <i>Quick stop active</i> . If the motor comes to standstill, the switch to state <i>Switch on disabled</i> takes place automatically. While the state machine is in state <i>Quick stop active</i> , command <i>Enable operation</i> can be used to switch it back to state <i>Operation enable</i> . |
| → Fault reaction active | This state change is brought on when an error occurs and cannot be triggered by a command from the user. It can be triggered by error types classified as an "Error" (see "Error code" on page 2694). (The other error types classified as "Warning" only cause the "Warning" bit to be set in the status word and do not cause a state change of the state machine.) The motor voltage is cut off and the state machine immediately changes to state <i>Fault</i> . The error code register contains the error type (see table in "Error code" on page 2694). The highest priority error is shown. The priority corresponds to the order in the error code table. |
| Fault → Switch-on disabled | This state change is brought on by the <i>Fault reset</i> command. However, the state only changes if no more errors are present when the command is written. All errors and warnings are reset. The error code register contains 0 or the warning code if a warning is still present. |

Table 518: State machine - State change

9.25.8.15.10 NetTime Technology

For a description of NetTime Technology, see ["NetTime Technology" on page 3035](#).

9.25.8.15.11 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|---------------------------|--------|
| Function model "Standard" | 250 µs |
| Function model "Ramp" | 250 µs |

9.25.8.15.12 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|---------------------------|--------|
| Function model "Standard" | 250 µs |
| Function model "Ramp" | |
| Inputs | 250 µs |
| Outputs ¹⁾ | 25 ms |

1) Depends on the configuration of the ["movement profile generator" on page 2684](#).

9.25.9 X20SM1436-1

Data sheet version: 1.17

9.25.9.1 General information

The stepper motor module is used to control stepper motors with a nominal voltage of 24 to 48 VDC ($\pm 25\%$) at a motor current up to 2.5 A (3.5 A peak). In addition, this module has 4 digital inputs that can be used as limit switches or encoder inputs.

Due to the individual adjustment of the coil currents, the motor is only operated with the current it actually needs. This simplifies the selection of the available motors and prevents unnecessary heating. Because this affects energy consumption and thermal load, the effects are positive on the service life of the complete system. Complete flexibility is achieved through the use of independently adjustable holding, maximum and nominal current values. The current for microsteps is automatically adjusted to the configured current values.

In addition, the module contains a sensorless, load-dependent current control. Depending on the operating situation and load, the module regulates the current downwards. Energy savings up to 75% are possible in this way.

The automatic motor identification system is an enormous help during standstills. The stepper motor modules can identify the connected motors using their coil characteristics and generate feedback in the form of an analog value. This makes it possible to detect not only wiring errors, but also incorrect motor types being used mistakenly. A stall detection mechanism is integrated to analyze the motor load. Detection of the stall is defined via a configurable threshold. This allows an overload or motor standstill to be detected precisely in many different types of applications.

- 1 stepper motor, 24 to 48 VDC $\pm 25\%$, 2.5 A (3.5 A peak)
- Resolution of current values at 1%
- Boost, nominal and holding current separately configurable
- Sensorless, load-dependent current control
- Integrated motor detection
- 256 microsteps per step
- Stall detection
- Complete integration in Automation Studio and CNC applications
- 4 inputs, 24 VDC, adjustable for ABR incremental encoders
- Open circuit detection for push-pull encoders
- Input ramp limit at max. 10 A
- Function model "Ramp" based on CANopen communication profile DS402

NetTime timestamp of the position and trigger time

It is not just the position value that is important for highly dynamic positioning tasks, but also the exact time the position is measured. The module is equipped with a NetTime function for this that supplies a timestamp for the recorded position and trigger time with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.25.9.2 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | Motor controllers |  |
| X20SM1436-1 | X20 stepper motor module, with current reduction function, module power supply 24 to 48 VDC $\pm 25\%$, 1 motor connection, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder, NetTime function | |
| | Required accessories | |
| | Bus modules | |
| X20BM11 | X20 bus module, 24 VDC keyed, internal I/O supply continuous | |
| X20BM15 | X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous | |

9.25.9.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|--------|-------|--------------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | Mode RESET |
| | | | Double flash | Mode BOOT (during firmware update) ¹⁾ |
| | | | Blinking | Mode PREOPERATIONAL |
| | | | On | Mode RUN |
| | e | Red | Off | Module not supplied with power or everything OK |
| | | | On | Error or reset state |
| | e + r | Green | Solid red / Single green flash | Invalid firmware |
| | | | On/Off | Input state of the corresponding digital input |
| | 1 - 4 | Green | Blinking | Open circuit or not connected |
| On | | | The motor is active. | |
| M | Orange | On | The motor is active. | |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.25.9.5 Pinout

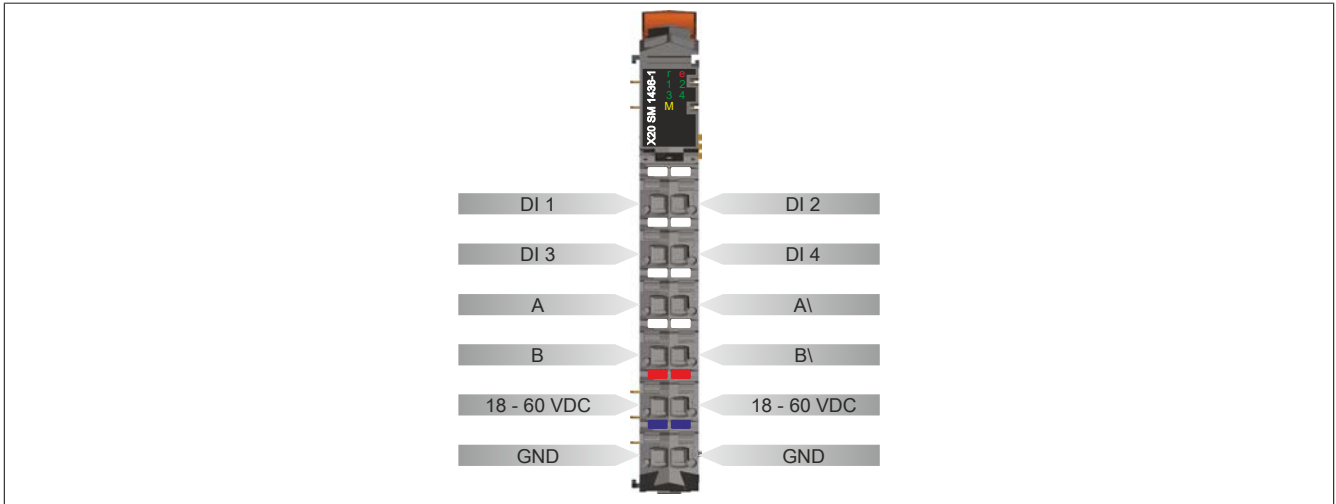

Per standard EN 60204-1, a cable cross section of 0.75 mm² or larger must be used for the motor outputs for the maximum motor current of 3.5 A. To guarantee full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into account when selecting the attachment cable.

Warning!

The terminal block is not permitted to be connected or disconnected during operation.

Information:

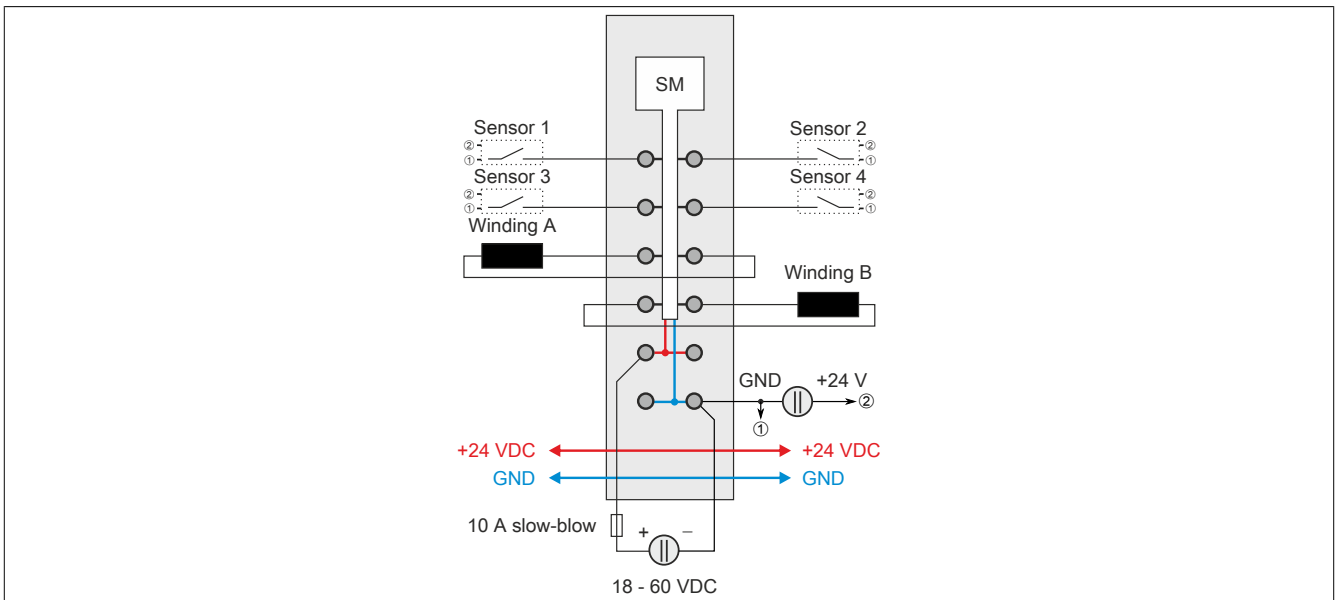

Shielded motor cables must be used in order to meet the limit values per standard EN 55011 (emissions).

9.25.9.6 Connection example

Information:

This module can only be operated if supplied with power via the terminal block.

For the wiring of sensors 1 to 4 see "Push-pull input circuits" on page 2703

9.25.9.6.1 Push-pull input circuits

The digital inputs of the module are equipped with open-circuit detection and therefore designed for push-pull circuits.

Information:

If no push-pull circuit is used, an open sensor contact is interpreted by the module as an open circuit.

Circuit variants

The size of the resistor depends on the sensor used and must therefore be calculated in each individual case.

9.25.9.7 Connection options for digital inputs

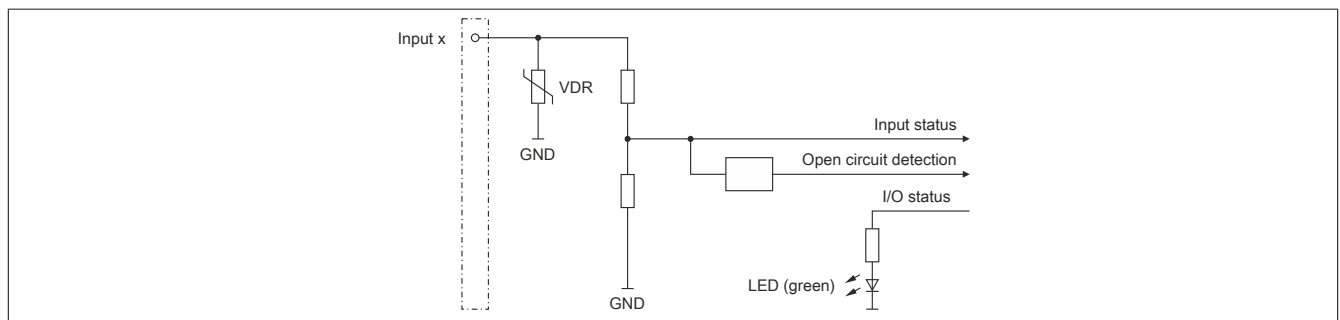

Function model "Standard"

| Channel | Function | |
|---------|---------------|---------------|
| DI 1 | Digital input | A |
| DI 2 | Digital input | B |
| DI 3 | Digital input | R |
| DI 4 | Digital input | Trigger input |

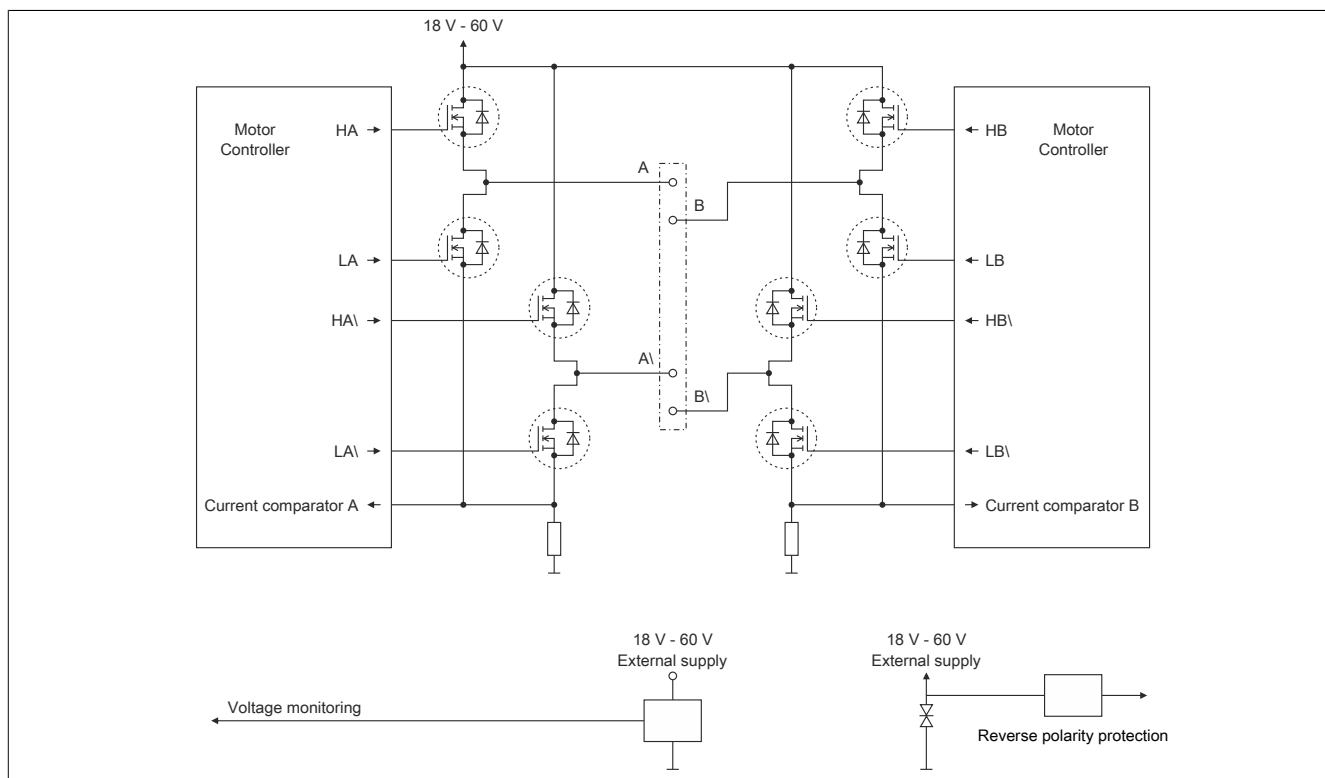

Function model "Ramp"

| Channel | Function | | |
|---------|---------------|---------------|-----------------------|
| DI 1 | Digital input | A | A |
| DI 2 | Digital input | B | B |
| DI 3 | Digital input | R | Negative limit switch |
| DI 4 | Digital input | Digital input | Positive limit switch |

9.25.9.8 Input circuit diagram

9.25.9.9 Output circuit diagram

9.25.9.10 Motor cutoff in the event of overvoltage

The module power supply voltage is continually monitored. Its status can be read. Error "[Module power supply error](#)" is reported if the voltage is greater than or less than the limit values.

If the supply voltage in the module overshoots or undershoots the limit values (e.g. during regenerative operation), the motor output is cut off!

If the supply voltage is within the permissible range again, the error must first be [acknowledged](#). The output stage can then be switched on again.

Limit values for the supply voltage

| | Drive cut off | Drive switched back on |
|-------------|---------------|------------------------|
| Lower limit | <17.4 V | >17.8 V |
| Upper limit | >60.3 V | <58.6 V |

9.25.9.11 Shutdown in the event of overtemperature (starting at 110°C)

If the module temperature reaches or overshoots the limit value of 110°C, the module performs the following actions:

- Sets the "overtemperature" error bit
- Cuts off the outputs (short-circuited)

As soon as the temperature is reduced below 110°C again, the error must be acknowledged with "OvertemperatureAcknowledge" so that the channels can be switched on again.

9.25.9.12 Power supply dimensioning

The motor's current consumption depends on the defined motor currents, the available power and the actual motor being used.

| Example | |
|--|-------------------|
| Model number of the motor | 80MPD5.300S000-01 |
| Configured current in the motor module | 3 A |
| Supply voltage of the motor module | 48 VDC |
| Motor load | 1 Nm |

Table 521: Power supply dimensioning example - Basic data

Figure 188: Power supply dimensioning example - Power/Speed relationship

The example is based on a constant load throughout the entire speed range.

An increase in the motor load causes an increase in the effective current of the I/O power supply.

9.25.9.13 Fuse protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load but is always less than the motor current. Make sure the maximum nominal current of 10 A is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the mains power input and the rated current of the used fuse are chosen according to the current-carrying capacity such that the permissible current-carrying capacity of the selected cable cross section (depending on wiring, see table) is greater than or equal to the current load in the mains power input. The rated current of the fuse protection must be less than or equal to the permissible current-carrying capacity of the selected cable cross section (depending on the how it is installed, see table):

$$\begin{array}{ccccc} I_{\text{Power system}} & \leq & I_b & \leq & I_z \\ \text{Power system} & \leq & \text{Fuse} & \leq & \text{Line/cable} \end{array}$$

| Wire cross section [mm ²] | Current-carrying capacity of cable cross section I_z / rated current of fuse I_b [A] depending on the to type of wiring at an ambient air temperature of + 40°C per EN 60204-1 | | | |
|---------------------------------------|--|-----------|-----------|-----------|
| | B1 | B2 | C | E |
| 1.5 | 13.5 / 13 | 13.1 / 10 | 15.2 / 13 | 16.1 / 16 |
| 2.5 | 18.3 / 16 | 16.5 / 16 | 21 / 20 | 22 / 20 |

Table 522: Cable cross section of the mains power input depending on the type of wiring

The tripping current of the fuse is not permitted to exceed the rated current of the fuse I_b .

| Type of wiring | Description |
|----------------|--|
| B1 | Wires in conduit or cable duct |
| B2 | Cables in conduit or cable duct |
| C | Cables or wires on walls |
| E | Cables or wires on open-ended cable tray |

Table 523: Type of wiring used for the mains power input

9.25.9.14 Let-through energy I²T

The module is designed for a continuous current of 2.5 A. A higher current can be temporarily drawn, however. The following points must be observed:

- The module is designed for a let-through energy of 194 A²s for a period of 30 seconds.

Information:

Exceeding the maximum let-through energy can result in damage to the module.

- If maximum current I_{boost} is drawn for maximum time t_{boost} , the continuous current of 2.5 A can be drawn for the remaining time of 30 seconds.
- If maximum current I_{boost} is drawn for more than maximum time t_{boost} , the current is not permitted to exceed the calculated residual current for the remaining time of 30 seconds (see example below).
- At the end of a 30 second period with increased current consumption, 2.5 A continuous current or a higher current can be drawn again.

Calculating the residual current

$$I_{\text{boost}}^2 \cdot t_{\text{boost}} + I_{\text{residual}}^2 \cdot (30 - t_{\text{boost}}) \leq 194 \text{ A}^2 \text{ s}$$

$$I_{\text{residual}} = \sqrt{\frac{194 \text{ A}^2 \text{ s} - I_{\text{boost}}^2 \cdot t_{\text{boost}}}{30 \text{ s} - t_{\text{boost}}}}$$

Example

A boost current of 3.2 A is needed for a duration of 3 seconds. According to the formula, the residual current of 2.45 A is not permitted to be exceeded for the remaining 27 seconds.

$$I_{\text{residual}} = \sqrt{\frac{194 \text{ A}^2 \text{ s} - 3.2 \text{ A}^2 \cdot 3 \text{ s}}{30 \text{ s} - 3 \text{ s}}} = 2.45 \text{ A}$$

I_{boost} values if $I_{2T} = 194 \text{ A}^2 \text{ s}$ and $I_{\text{residual}} = 2.5 \text{ A}$

| t_{boost} s | I_{boost} A | t_{residual} s | t_{boost} s | I_{boost} A | t_{residual} s |
|-------------------------|-------------------------|----------------------------|-------------------------|-------------------------|----------------------------|
| 1 | 3.50 | 29 | 16 | 2.58 | 14 |
| 2 | 3.08 | 28 | 17 | 2.58 | 13 |
| 3 | 2.90 | 27 | 18 | 2.57 | 12 |
| 4 | 2.81 | 26 | 19 | 2.57 | 11 |
| 5 | 2.75 | 25 | 20 | 2.56 | 10 |
| 6 | 2.71 | 24 | 21 | 2.56 | 9 |
| 7 | 2.68 | 23 | 22 | 2.56 | 8 |
| 8 | 2.66 | 22 | 23 | 2.56 | 7 |
| 9 | 2.64 | 21 | 24 | 2.55 | 6 |
| 10 | 2.63 | 20 | 25 | 2.55 | 5 |
| 11 | 2.62 | 19 | 26 | 2.55 | 4 |
| 12 | 2.61 | 18 | 27 | 2.55 | 3 |
| 13 | 2.60 | 17 | 28 | 2.55 | 2 |
| 14 | 2.59 | 16 | 29 | 2.54 | 1 |
| 15 | 2.59 | 15 | 30 | 2.54 | 0 |

These values correspond to the following curve for let-through current I_{2T} :

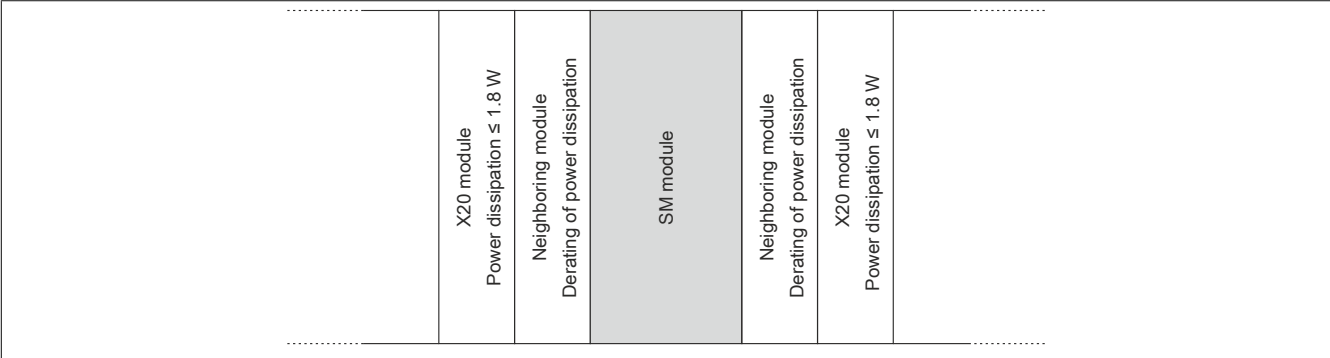

9.25.9.15 Derating

Only modules with a maximum power dissipation of 1 W are permitted to be operated next to the SM module. To ensure proper operation, observe the derating values listed below:

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

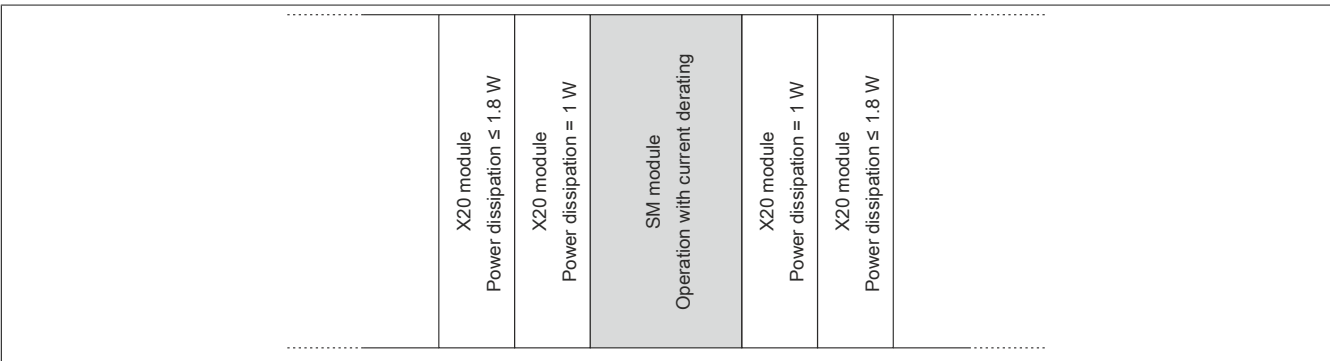

Power dissipation derating for neighboring modules

The power dissipation of immediate neighboring modules of the SM module is permitted to be 1 W. If the SM module is operated at the rated load over the entire temperature range (2.5 A nominal current), the power dissipation of neighboring modules must be derated starting at 45°C.

Current derating of the SM module

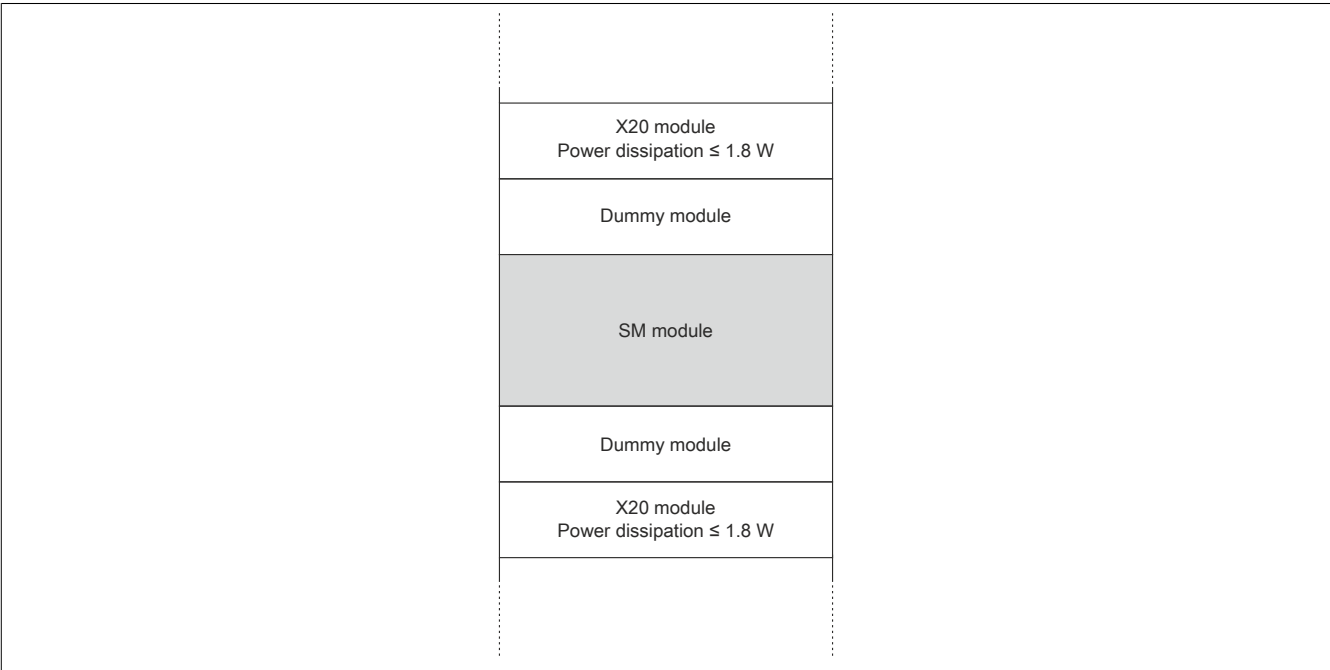

If the power dissipation of the neighboring modules to the SM module is 1 W, then the current of the SM module must be derated starting at 45°C.

Derating for vertical mounting orientation

When operating the module in a vertical mounting orientation, dummy modules must be connected as neighboring modules. There is no derating in this configuration.

9.25.9.16 Register description

9.25.9.16.1 mapp Motion system requirements

This module can be operated with mapp Motion function blocks. The following minimum versions are required for this:

- Upgrade version 2.2.0.0
- Automation Studio 4.7.2
- Automation Runtime 4.72

9.25.9.16.2 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

1) The offset specifies the position of the register within the CAN object.

9.25.9.16.5.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "Using I/O modules on the bus controller" on page 3789.

9.25.9.16.5.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.25.9.16.6 Register description: General registers

9.25.9.16.6.1 General configuration registers

Determining the SGT parameters

Due to the dependence of the [MotorLoad value](#) on motor-specific properties and application-specific load and speed requirements, the operating conditions should be matched to the actual application.

To reliably detect a standstill of the motor, the stall threshold must be determined. The stall threshold should be a value within the operating limits and slightly higher than the minimum value before an actual motor standstill occurs.

- Parameter [SGT_Value01x](#) is used to compensate for an offset that results from the back EMF of the motor. For this purpose, the maximum load that the motor can run without blocking must be determined. Ideally, the MotorLoad load value should drop to 0 before a step loss due to overload causes the motor to stop. If the value of [SGT_Value01x](#) is set so that a value of 0 is displayed at maximum motor load, then the stall is precisely detected and the [stall error bit](#) is set correctly. For some motors, however, stall detection is very difficult to use or cannot be used at all. With these motors, no settings can be determined where the motor stops without slipping, e.g. due to electrical parameters or too little magnetic field feedback from the motor.
- [SGT_Speed01x](#) sets the threshold value at which speed the determined [SGT_Speed01x](#) becomes active. These are:

| | |
|---------------------|--|
| SGT_Value01a | From 0 to SGT_Speed01a |
| SGT_Value01b | From SGT_Speed01b to maximum |

Since the [MotorLoad value](#) drops to 0 during acceleration from standstill, this would be incorrectly detected as a stall and the motor would stop again immediately. Register [StallDetectMinSpeed01](#) can therefore be used to set a minimum speed at which stall detection is enabled.

Information:

- **At very low motor speeds (<1 revolution/second), stall detection cannot be carried out reliably due to low back EMF values.**
- **At very high motor speeds, at which the sinusoidal motor current can no longer be impressed into the motor coil, poor responsiveness can also occur.**

Determining the motor load characteristic curve

To be able to set the points (SGT_Value01a and SGT_Value01b) for the offset of the MotorLoad value, creating a motor load characteristic curve is helpful.

This graph shows an example of 200 steps per revolution:

| | SGT_Value | SGT_Speed |
|-----------|-----------|--|
| Value (a) | 4 | 129 revolutions/minute = 430 steps/second |
| Value (b) | 12 | 392 revolutions/minute = 1307 steps/second |

Legend

- Green line Motor load characteristic curve without load
- Red line Offset-corrected motor load characteristic curve
- Black line Interpolated motor load characteristic curve
- * Minimum speed for stall detection (>10 rpm)
- ** Back EMF reaches supply voltage

Since the back EMF increases with increasing speed (MotorLoad value decreases to 0) and counteracts, there is a maximum speed for stall detection.

SGT speed

Name:

SGT_Speed01a to SGT_Speed01b

The associated speed value for the respective SGT_Value can be set in these registers.

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | In microsteps / X2X cycle (function model "Standard") In microsteps/cycle (function models "Bus controller" and "Ramp") |

SGT correction values

Name:

SGT_Value01a to SGT_Value01b

These registers optimize the motor load measurement.

The SGT value (Stallguard threshold) optimizes the motor load measurement. A negative value increases the sensitivity of the measurement; a positive value decreases it.

The correction value used depends on the value of SGT_Speed. The following applies:

- SGT_Value01 is used if the motor speed ≤ SGTSpeed01.
- SGT_Value02 is used if the motor speed ≥ SGTSpeed02.
- If the motor speed lies between the values, the SGT_Value is interpolated linearly.

The initial value for the optimization is 0. Values below -10 or over +10 should not be used.

| Data type | Values |
|-----------|-----------|
| INT | -64 to 63 |

Load-dependent current control

Load-dependent current control uses the **MotorLoad** value to reduce the current for the motor when the motor is only slightly loaded. In addition to saving energy, this also reduces the noise level of the motor. In addition, the motor is not heated as much. If a heavier load is again placed on the motor, the motor current is increased and thus more torque can be applied.

To set the load-dependent current control, 2 parameters must be set with "**MotorLoad_UpperLimit**" on page 2716 and "**MotorLoad_LowerLimit**" on page 2716 so that they can be increased or decreased as needed.

Stall detection for constant speed

If stall detection is only needed for a constant speed, the module can be configured as follows:

- 1) Set the initial values.
 - Disable current control. (**CurrentControlEnabel01** = 0)
 - Disable stall detection. (**StallDetectMinSpeed01** = 65535)
 - Set register **SGT_Speed01x** to 0.
 - Set register **SGT_Value01x** to 0.
- 2) Operate the motor at the speed needed for the application without load and observe the **MotorLoad** value.
- 3) Adjust the value.
 - a) Slowly increase the load on the motor. If the motor stops before the **MotorLoad** value indicates 0, reduce **SGT_Value01x** by 1.

Information:

Registers **SGT_Value01a and **SGT_Value01b** must always be set to the same value!**

- b) If the **MotorLoad** value is 0 before the motor stops, increase **SGT_Value01x** by 1. The optimal setting is achieved when the **MotorLoad** value remains above 0 at the maximum load necessary. If the value becomes 0, the maximum load on the motor is exceeded. In this case, bit 0 "StallError" is set in register **Error status**.
- 4) In register **StallDetectMinSpeed01**, set the speed value from which stall detection is enabled.

Stall detection for variable speeds

If stall detection is needed for a range of speeds ([SGT_Speed01a](#) and [SGT_Speed01b](#)), the module can be configured as follows:

- 1) Set the initial values.
 - Disable current control. ([CurrentControlEnabel01](#) = 0)
 - Disable stall detection. ([StallDetectMinSpeed01](#) = 65535)
 - Set register [SGT_Speed01x](#) to 0.
 - Set register [SGT_Value01x](#) to 0.
- 2) Operate the motor at the start of the speed range ([SGT_Speed01a](#)) without load and observe the [MotorLoad value](#).
- 3) Adjust the value.
 - a) Slowly increase the load on the motor. If the motor stops before the [MotorLoad value](#) indicates 0, reduce [SGT_Value01x](#) by 1.
 - b) If the [MotorLoad](#) value is 0 before the motor stops, increase [SGT_Value01x](#) by 1. The optimal setting is achieved when the [MotorLoad](#) value remains above 0 at the maximum load necessary. If the value becomes 0, the maximum load on the motor is exceeded. In this case, bit 0 "StallError" is set in register [Error status](#).
- 4) Operate the motor at the end of the speed range ([SGT_Speed01b](#)) without load and observe the [MotorLoad value](#).
- 5) Adjust the value, see 3.
- 6) Set the determined range values.

The [SGT_Value0x](#) values between the range start and range end are interpolated linearly.

 - Set [SGT_Value01a](#) and [SGT_Speed01a](#) for the range start with the determined values.
 - Set [SGT_Value01b](#) and [SGT_Speed01b](#) for the range end with the determined values.
- 7) In register [StallDetectMinSpeed01](#) , set the speed value from which stall detection is enabled.

Configuring current control

Name:

CfO_SmartEnable01

The values for load-dependent current control can be set in this register. For reduced motor loads, the power supply can be reduced to a minimum of 25% nominal current in order to save electricity.

For increased motor loads, the module automatically adjusts the power supply according to the set values.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|---|---------|--|
| 0 - 3 | MotorLoad_LowerLimit | 0 | Current control disabled (bus controller default setting) |
| | | 1 to 15 | |
| 4 | Reserved | - | |
| 5 - 6 | Current increase¹⁾ | 0 | 1 measured values (bus controller default setting) |
| | | 1 | 2 measured values |
| | | 2 | 4 measured values |
| | | 3 | 8 measured value |
| 7 | Reserved | - | |
| 8 - 11 | MotorLoad_UpperLimit | 0 to 15 | |
| 12 | Reserved | - | |
| 13 - 14 | Current decrease¹⁾ | 0 | 32 measured values (bus controller default setting) |
| | | 1 | 8 measured values |
| | | 2 | 2 measured values |
| | | 3 | 1 measured value |
| 15 | Current reduction | 0 | Reduction to 50% of the nominal current (bus controller default setting) |
| | | 1 | Reduction to 25% of the nominal current |

1) The measured values are recorded with each full step of the motor.

MotorLoad_LowerLimit

Increase of the current up to a maximum of 100% of the nominal current set in register "ConfigOutput04" on page 2718 if `MotorLoad` < (`MotorLoad_LowerLimit` * 32). If `MotorLoad_LowerLimit` = 0, load-dependent current control is disabled.

Current increase

Specifies the number `MotorLoad` measured values that are less than or equal to the limit value (`MotorLoad_LowerLimit` * 32) in order to increase current.

MotorLoad_UpperLimit

Reduction of the current if `MotorLoad` > (`MotorLoad_LowerLimit` + `MotorLoad_UpperLimit` + 1) * 32.

Current decrease

Number of `MotorLoad` measured values that are greater than or equal to the limit value (`MotorLoad_LowerLimit` + `MotorLoad_UpperLimit` + 1) * 32 in order to decrease the current.

Current reduction

Maximum reduction of the current to 25% or 50% of the nominal current.

9.25.9.16.7 Register description: Function model "Standard", general registers**9.25.9.16.7.1 Configuration registers****Minimum speed for stall detection**

Name:

StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled. This means that stall detection principally does not work at low speeds.

| Data type | Values | Information |
|-----------|-------------|------------------------------------|
| UINT | 0 to 65,535 | Minimum speed in steps per second. |

Full step threshold

Name:

FullStepThreshold01

This register configures a rotational speed. When this defined speed has been reached, the drive will automatically change from microsteps to full step mode. This makes it possible to optimize the torque at higher speeds, while microstep mode ensures optimal radial runout at lower speeds.

It does not make sense to change to full step mode at a standstill because fine positioning would then no longer be possible. This is why value "0" does not make sense in the full step threshold register and is interpreted as disabling full step mode (i.e. the motor will always be operated in microstep mode).

| Data type | Values | Information |
|-----------|-------------|-------------------------|
| UINT | 0 | Full step mode disabled |
| | 1 to 65,535 | Steps/second |

Example

Microstep mode should change to full step mode at 500 steps/second. On a motor with 200 steps per revolution, this would be equal to a speed of:

$$T^{-1} = \frac{500 \text{ steps/second}}{200 \text{ steps/revolution}} = 2.5 \frac{\text{revolutions}}{\text{second}} = 150 \text{ min}^{-1}$$

Holding current, nominal current and maximum current

Name:

ConfigOutput03 (holding current)

ConfigOutput04 (nominal current)

ConfigOutput05 (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

Information:

The maximum current must always be configured higher than the nominal current.

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

| Register | Description |
|-----------------|---|
| Nominal current | Current during normal operation |
| Maximum current | Should be selected if a higher motor torque is required briefly during acceleration phases. |
| Holding current | The holding current should be used in situations when less torque is required (e.g. at a standstill). This reduces the amount of heat generated by the motor. |

Switching between preset current values (holding current, rated current, maximum current):

| Function model | Switching between preset current values at runtime |
|---------------------------------------|--|
| Standard | Using bits 14 and 15 in registers "Motor StepX" on page 2723 |
| Standard with enabled SDC information | Using register "Motor current" on page 2728 |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 200 | Percent of the module's rated current <ul style="list-style-type: none"> • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 200% corresponds to the maximum current of the motor bridge power unit listed in the technical data. |

Counter configuration

Name:

ConfigOutput09

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------------|-------|--|
| 0 | ABR latch function | 0 | Negative edge: Disable ABR latch function |
| | | 1 | Positive edge: Enable ABR latch function. After a latch event has occurred, the latch function can be started again on a new rising edge. |
| 1 - 2 | Definition of the latch mode | 00 | ABR latch counter state unconditionally |
| | | 01 | ABR latch counter state on a positive edge of input R |
| | | 10 | ABR latch counter state on a negative edge of input R |
| | | 11 | Reserved |
| 3 | | 0 | <ul style="list-style-type: none"> • Position sync: Internal position counter • Position async: ABR counter state • Position latched sync: Internal position counter • Position latched async: ABR counter state |
| | | 1 | <ul style="list-style-type: none"> • Position sync: ABR counter state • Position async: Internal position counter • Position latched sync: ABR counter state • Position latched async: Internal position counter |
| 4 - 7 | Reserved | | |

1) These registers are not available in function model "Standard" with SDC information enabled.

Motor ID trigger

Name:

MotorIdentTrigger

With this register, a measurement of the motor ID can be initiated acyclically (see "[Motor identification](#)" on page 2721). The application must ensure that the conditions for measurement are met (see table "Notes" in register "[Motor identification](#)" on page 2721).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|---|
| 0 | | 0 | No effect |
| | | 1 | Positive edge triggers motor identifier measurement |
| 1 - 7 | Reserved | 0 | |

9.25.9.16.7.2 Registers for reading back the configuration

Reading back the holding current, nominal current and maximum current

ConfigOutput03Read (holding current)

ConfigOutput04Read (nominal current)

ConfigOutput05Read (maximum current)

These registers are used to read the respective current values in percent.

| Register | Description |
|-----------------|--|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases |
| Holding current | Current when motor is at standstill |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 255 | Percentage of module's nominal current (100% corresponds to the nominal current of the motor bridge power unit in the technical data) |

9.25.9.16.7.3 Communication registers

Measuring motor load

Name:

MotorLoad

This register contains the current measured load value for stall detection. A high value indicates a small load on the motor; the lower the value, the higher the motor load. The SGT values (see "[SGT speed](#)" on page 2714 and "[SGT correction values](#)" on page 2714) should be set so that the motor load returns value 0 at maximum load (shortly before stall).

This register can be shown and hidden via the module configuration.

| Data type | Values |
|-----------|-----------|
| UINT | 0 to 1023 |

Module configuration 1

Name:

ConfigOutput02

The number of transfer values and the resolution of microsteps for the drive can be configured in this register.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 | The setting for these two bits determines the meaning of bits 2 and 3 in register "Input counter value" on page 2725. | x | |
| 1 - 2 | Reserved | 0 | |
| 3 - 4 | Number of transfer values per X2X Link cycle (see "Motor StepX" on page 2723) | 00 | $1 \times \Delta s / \Delta t$ (transfer values: MotorStep0) |
| | | 01 | $2 \times \Delta s / \Delta t$ (transfer values: MotorStep0 - MotorStep1) |
| | | 10 | $4 \times \Delta s / \Delta t$ (transfer values: MotorStep0 - MotorStep3) |
| | | 11 | Reserved |
| 5 - 6 | Resolution of microsteps for the following registers: <ul style="list-style-type: none"> "Motor StepX" on page 2723 "Position sync/async" on page 2720 | 00 | Resolution: 5 bits (bits 0 - 4) microsteps; 8 bits (bits 5 - 13) full steps |
| | | 01 | Resolution: 6 bits (bits 0 - 5) microsteps; 7 bits (bits 6 - 13) full steps |
| | | 10 | Resolution: 7 bits (bits 0 - 6) microsteps; 6 bits (bits 7 - 13) full steps |
| | | 11 | Resolution: 8 bits (bits 0 - 7) microsteps; 5 bits (bits 8 - 13) full steps |
| 7 - 15 | Reserved | 0 | |

Position sync/async

Name:

PositionSync (function model 1 - "Standard" with SDC)

ActPos01 (function model 0 - "Standard" without SDC)

Positionasync

Depending on the [Counter configuration](#), these registers can be used to read either the internal position counter or the counter value on the ABR input.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

| Register | Counter configuration | |
|--------------------------|---------------------------|---------------------------|
| | Bit 3 = 0 | Bit 3 = 1 |
| Position sync (ActPos01) | Internal position counter | ABR counter |
| Position async | ABR counter | Internal position counter |

Internal position counter

The internal position counter is the position calculated by the SM module (position setpoint). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the "Module configuration 1" on page 2720). In function model "Standard" with SDC, this value is defined as "8-bit microstep" and cannot be changed.

Example of the internal position counter format (7-bit microsteps, i.e. set bit 5 and 6 of the module configuration to binary 10):

ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

Motor identification

Name:

Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. After successful measurement, this register contains the time [µs] required to apply a current increase of $\Delta I = 1 \text{ A}$ to a motor winding.

This depends on:

- Operating voltage
- Inductance and resistance of the motor winding

| Notes | | |
|-----------|---|--|
| 1) | To achieve reproducible results, the measurement must be made under the following defined conditions: | |
| a) | Motor is at standstill. | |
| b) | The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: <ul style="list-style-type: none"> • Full steps are divisible by 4. • Microsteps = 0 | |
| 2) | Condition 1b) is fulfilled after a the SM module is reset or switched on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application. | |
| 3) | The current range from approximately 1/3 of the nominal current up to the nominal current is used as operating range for determining the motor identifier. | |
| Data type | Motor ID values | Explanation |
| UINT | 0 | No motor identifier available (after switching on for as long as the measurement conditions are not met) |
| | 1 to 32767 | Valid range of values for the motor ID register (in µs) |
| | 65534 | Invalid value: Overflow |

Error status

Name: The names of the bits are different depending on whether [SDC information](#) is enabled or disabled.

Without SDC

StallError

Overtemperature

ErrorCurrentError

OvercurrentError

-

With SDC

StallError01

Overtemperature01

ErrorCurrentError01

OvercurrentError01

DrvOK01

OpenCircuit01 to OpenCircuit04

The current error status of the drive is indicated in this register. Each bit indicates a certain error or status. If an error is registered in bits 0 to 3, then the corresponding bit remains set until the error has been acknowledged (see "[Module configuration 2](#)" on page 2726 and "[Error acknowledgment](#)" on page 2729).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |

| | | 1 | Open circuit detected |
| ... | | ... | |
| 15 | Open circuit OpenCircuit04 | 0 | No open circuit |
| | | 1 | Open circuit detected |

1) Only when SDC information is enabled

Overtemperature error

The "Overtemperature" error bit can be set for the following reasons:

- A specific temperature was exceeded near the channel due to overload
- The module temperature rises above the limit (see ["Shutdown in the event of overtemperature \(starting at 110°C\)" on page 2704](#)).

Current error

This error bit occurs whenever the required current cannot be supplied to the motor windings. This can be (but is not necessarily) caused by an open circuit. At higher speeds (depending on the motor), this error can also occur without an open circuit. In this case it is simply no longer possible to supply the desired current to the motor windings. Because of the Back-EMF on the motor, this bit is set at slightly lower speeds if the motor is operated with no load compared with full or partial loads.

Overcurrent error

Overcurrent occurs if there is not enough voltage for the motor winding (e.g. short circuit).

Status of the drive

The status of the drive is only shown when SDC information is enabled. The drive bit is 1 when the following conditions are met:

- Motor turned on (see ["Motor current" on page 2728](#))
- MotorID measurement is completed
- Motor is supplied with current
- Motor settling time has passed
- Supply voltage is in the valid range
- No overtemperature fault
- Preset position value is valid (see ["SDC life sign monitoring" on page 2728](#))

Open circuit

The module is equipped with open circuit detection for the digital inputs. If the digital input is not connected to ground or to 24 V, an open circuit is detected.

9.25.9.16.8 Register description: Function model "Standard" without SDC information

9.25.9.16.8.1 Communication registers

Motor StepX

Name:

MotorStep0 to MotorStep3

These registers specify the number and direction of steps that must be moved by the module during the next X2X cycle and also select the motor current (see also "[Holding current, nominal current and maximum current](#)" on page 2718).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|-------|-------------------|
| 0 - 12 | Number of steps for the module to move during the next X2X cycle | x | |
| 13 | Direction of movement | 0 | Positive |
| | | 1 | Negative |
| 14 - 15 | Selection of motor current | 00 | Motor not powered |
| | | 01 | Holding current |
| | | 10 | Nominal current |
| | | 11 | Maximum current |

Depending on the necessary resolution and maximum configurable speed, module configuration 1 can be used to specify which bit position is used as the 1s position for full steps (see bits 5 and 6 of "[Module configuration 1](#)" on page 2720).

Example for 5-bit microsteps (set bits 5 and 6 of the module configuration to binary 00):

The number of transfer values per X2X cycle is specified by bits 3 and 4 in the module configuration 1 (see "[Module configuration 1](#)" on page 2720). If only one transfer value (bits 3 and 4 = 00) is specified, then the motor is advanced by MotorStep0 until the next X2X cycle. If 2 or 4 transfer values are specified, they are added and executed in the next X2X cycle.

Position latched sync-async

Name:

PositionLatchedSync

PositionLatchedASync

The position counter (internal position counter or ABR counter) is applied at the latch event (see "Module configuration 2" on page 2726). Bits 3 and 7 of register "Counter configuration" on page 2718 are used to determine which counter state (internal position counter or ABR encoder) should be saved in registers "Position latched sync" and "Position latched async".

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

| Register | Counter configuration | |
|----------------|---------------------------|---------------------------|
| | Bit 3 = 0 | Bit 3 = 1 |
| Position sync | Internal position counter | ABR counter |
| Position async | ABR counter | Internal position counter |

Internal position counter

The internal position counter is the position calculated by the module (position setpoint). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the "Module configuration 1" on page 2720).

Example of the internal position counter format (7-bit microsteps, i.e. set bit 5 and 6 of the module configuration to binary 10):

ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

usSinceTrigger

Name:

usSinceTrigger

This register indicates the time in μs that has passed since the trigger event occurred (see "Module configuration 2" on page 2726).

Information:

The absolute accuracy of the trigger can be delayed up to 5 μs due to the input filter of the digital inputs.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Stepper latch trigger status

Name:

LatchInput

LatchDone

TriggerInput

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|---|
| 0 | Latch input: | x | Digital input for the latch event (level) |
| 1 | LatchDone | x | Changes its state each time the counter state is successfully latched (reset value = 0) |
| 2 - 3 | Reserved | - | |
| 4 | TriggerInput | x | Trigger input (level) |
| 5 - 7 | Reserved | 0 | |

9.25.9.16.8.2 Input counter value

Name:

ModulePowerSupplyError

StatusInput01 to StatusInput04

This register indicates the state of the digital inputs and counters.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|---|--|
| 0 | ModulePowerSupplyError | 0 | OK |
| | | 1 | Module power supply error |
| 1 | Reserved | 0 | |
| 2 | StatusInput01 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 1 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | x | Ref toggle bit for counter 1: The state of this bit is changed after homing is completed. |
| 3 | StatusInput02 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 2 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | 0 | The homing procedure for the ABR counter is active. |
| | | 1 | The homing procedure of the ABR counter is completed. |
| 4 | StatusInput03 | 0 or 1 | Input state - Digital input 3 |
| 5 | StatusInput04 | 0 or 1 | Input state - Digital input 4 |
| 6 - 7 | Reserved | 0 | |

9.25.9.16.8.3 Configuration registers

Module configuration 2

Name:

StartLatch

TriggerEdgePos

TriggerEdgeNeg

StartTrigger

TriggerEdge

ClearError

CurrentControlEnable

The trigger functions for the stepper motor can be configured with this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|---|
| 0 | Latch function for stepper motor 2 Latch byte | 0 | The latch function for stepper motor position is disabled on the negative edge of this bit. |
| | | 1 | The latch function for stepper motor position is disabled on the positive edge of this bit. |
| 1 - 2 | Latch mode for stepper motor TriggerEdgePos (bit 1) TriggerEdgeNeg (bit 2) | 00 | Latch position of stepper motor unconditional |
| | | 01 | Latch position of stepper motor on positive edge of input DI 3 |
| | | 10 | Latch position of stepper motor on negative edge of input DI 3 |
| | | 11 | Reserved |
| 3 | TriggerEdge | 0 | Trigger edge (input DI 4) = Positive |
| | | 1 | Trigger edge (input DI 4) = Negative |
| 4 | Enable trigger (on change) StartTrigger | x | |
| 5 | ClearError | 0 | No effect |
| | | 1 | Error acknowledgment for motor (for more information, see "Error status" on page 2721) |
| 6 | Reserved | - | |
| 7 | CurrentControlEnable | 0 | Enable load-dependent current control |
| | | 1 | Disable load-dependent current control |

Trigger function procedure:

- Selection of the desired trigger edge using bit 3
- Enabling of the trigger function by changing the state of bit 4. Changing this bit deletes `usSinceTrigger` (μ s counter).
- When the trigger event occurs, μ s counter `usSinceTrigger` is started.
- Counter `usSinceTrigger` cannot overflow, i.e. the counter is stopped at $2^{16} - 1$ and retains this value until the next time the trigger function is enabled.

The trigger function can be re-enabled at any time by changing the state of bit 4, regardless of whether a trigger event has occurred or if `usSinceTrigger` has reached the maximum value.

Position sync 2

Name:

PositionSync02

This register contains the state of either the position counter or the ABR counter depending on [Counter configuration](#) (bit 3). It behaves exactly complementary to register "Position sync" on page 2720.

If "Position sync" contains the position counter, then register "PositionSync02" contains the ABR counter state, and vice versa.

By default, the register is not visible in the I/O map; it must first be enabled in the I/O configuration.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.9.16.9 Register description: Function model "Standard" with SDC information

9.25.9.16.9.1 Configuration registers

SDC configuration

Name:
SDCConfig01

This register can be used to enable/disable additional SDC information.

The additional cyclic registers are hidden or shown depending on whether SDC information is disabled or enabled. Compare the two variants of function model "Standard" [with](#) and [without enabled SDC information](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------------------------|-------|----------------------|
| 0 | Trigger edge | 0 | Rising trigger edge |
| | | 1 | Falling trigger edge |
| 1 - 5 | Reserved | 0 | |
| 6 | SDC life sign monitoring | 0 | Disabled |
| | | 1 | Enabled |
| 7 | SDC information ¹⁾ | 0 | Disabled |
| | | 1 | Enabled |

- 1) When the "SDC information" bit is enabled, the "EncOK01" bit is shown in the Automation Studio I/O mapping. This bit is linked to the ModulOK bit and always indicates its value.

Information:

Neither SDC information nor SDC life sign monitoring is permitted to be changed at runtime.

Module configuration 1 with SDC

Register "[Module configuration 1](#)" on page 2720 is ignored in function model "Standard" with SDC information enabled. The module behaves as follows, i.e. whether the module configuration was written in this way:

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 | Meaning of bits 2 and 3 in register " Input counter value " on page 2729 | | |
| 1 - 2 | Reserved | 0 | |
| 3 - 4 | Number of transfer values per X2X cycle | 00 | 1x Δs / Δt (transfer values: motor settings Motor1Step0) |
| 5 - 6 | Resolution of microsteps | 11 | 8-bit microsteps |
| 7 - 15 | Reserved | 0 | |

Motor settling time

Name:
MotorSettlingTime01

This register determines the motor setting time. The motor settling time determines the minimum time between when the motor is powered on to when the DrvOk bit is set (see "[Error status](#)" on page 2721). The setting is made in steps of 10 ms.

| Data type | Values | Information |
|-----------|----------|---------------------------------|
| USINT | 1 to 255 | 10 ms to 2.55 s, default: 10 ms |

Switch-off delay

Name:
DelayedCurrentSwitchOff01

If the [SDC life sign monitoring](#) is triggered (i.e. the [NetTime timestamp](#) is in the past) the motor is decelerated at nominal current with speed setpoint = 0.

Then the motor is switched off after the delay configured with this register.

| Data type | Values | Information |
|-----------|----------|--|
| USINT | 0 to 255 | 0 to 25.5 s in steps of 100 ms (default: 100 ms) |

9.25.9.16.9.2 Communication registers**SDC life sign monitoring**

Name:

SetTime01

The module uses SDC life sign monitoring to check whether valid values have been received for the speed setpoint.

SDC life sign monitoring is enabled in register "SDC configuration" on page 2727 by setting bit 6 (SDCSetTime = On).

If the specified [NetTime timestamp](#) is in the past, then an error is triggered for the motor axis (only when the motor is switched on). The module performs the following steps:

- 1) The CPU is informed of the error using the Drive bit (DrvOk) = 0
- 2) Braking at configured nominal current with speed setpoint = 0
- 3) Wait for configured turn-off delay to expire
- 4) Power off motor

When the timestamp is back within the valid range, the motor can be operated again by a rising edge on bit "DriveEnable" (see "[Motor current](#)" on page 2728) .

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Motor current

Name:

DriveEnable01

BoostCurrent01

StandstillCurrent01

CurrentControlEnable01

Bits 0 to 2 of this register control the motor's current feed.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|-------|---|
| 0 | DriveEnable01 | x | Motor powered |
| 1 | BoostCurrent01 | x | Maximum current |
| 2 | StandstillCurrent01 | x | Holding current |
| 3 - 6 | Reserved | 0 | |
| 7 | CurrentControlEnable01 | 0 | Load-dependent current control disabled |
| | | 1 | Load-dependent current control enabled |

The possible status of bits 0 to 2

| StandstillCurrent01 | BoostCurrent01 | DriveEnable01 | Description |
|---------------------|----------------|---------------|-----------------------------------|
| x | x | 0 | Motor not supplied with current |
| 0 | 0 | 1 | Rated current supplied to motor |
| 0 | 1 | 1 | Maximum current supplied to motor |
| 1 | 0 | 1 | Holding current supplied to motor |
| 1 | 1 | 1 | Holding current supplied to motor |

Lifecycle counter

Name:

LifeCnt

This register is incremented by one with each X2X Link cycle.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Input counter value

Name:

ModulePowerSupplyError

StatusInput01 to StatusInput04

This register indicates the state of the digital inputs and counters.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|---|--|
| 0 | ModulePowerSupplyError | 0 | OK |
| | | 1 | Module power supply error |
| 1 | Reserved | 0 | |
| 2 | StatusInput01 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 1 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | x | Ref toggle bit for counter 1: The state of this bit is changed after homing is completed. |
| 3 | StatusInput02 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 2 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | 0 | The homing procedure for the ABR counter is active. |
| | | 1 | The homing procedure of the ABR counter is completed. |
| 4 | StatusInput03 | 0 or 1 | Input state - Digital input 3 |
| 5 | StatusInput04 | 0 or 1 | Input state - Digital input 4 |
| 6 - 7 | Reserved | 0 | |

Error acknowledgment

Name:

ClearError01

This register can be used to acknowledge errors that have occurred on the motor.

For more info, see ["Error status" on page 2721](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|--------------------------------|
| 0 - 4 | Reserved | 0 | |
| 5 | ClearError01 | 0 | No effect |
| | | 1 | Error acknowledgment for motor |
| 6 - 7 | Reserved | 0 | |

Motor1Step0

Name:

Motor1Step0

This registers is used to specify the number and direction of steps that should be carried out by the module during the next X2X cycle.

The value is specified with a resolution of 1/256 of a full step (corresponds to 8-bit microsteps).

The direction of movement is derived from the value's sign:

| Data type | Values | Information |
|-----------|--------|--|
| INT | >0 | Movement in the positive direction in 1/256 full steps |
| | <0 | Movement in the negative direction in 1/256 full steps |

Unlike function model "Standard" without enabled SDC information, the motor current is selected using a separate register (see register ["Motor current" on page 2728](#)).

Home position

Name:

RefPulsePos01

These 2 registers have the following contents:

| Register | Description |
|--|--|
| Home position of the internal position counter | This register contains the home position of the internal position counter. |
| Home position for the ABR counter | This register contains the home position of the ABR counter. |

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Setting "Position sync" in the Automation Studio I/O configuration can be used to select which of the 2 registers is addressed by variable RefPulsePos01.

| Variables in Automation Studio | I/O configuration, counter 01, option "Position sync" | |
|--|---|---|
| | Stepper counter 01 is indicated on ActPos01 . | ABR counter 01 is indicated on ActPos01 . |
| RefPulsePos01 | Home position of the internal position counter | Home position of the ABR counter |
| Option "Position sync" for counter 1 also sets bit 3 in register " Counter configuration " on page 2718: | | |
| Bit 3 (counter 1) | 0 | 1 |

Reference pulse counter

Name:

RefPulseCnt01

These 2 registers have the following contents:

| Register | Description |
|---|---|
| Reference pulse counter for the internal position counter | The reference pulses of the internal position counter are counted in this register. |
| Reference pulse counter for the ABR counter | The reference pulses of the ABR counter are counted in this register. |

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Setting "Position sync" in the Automation Studio I/O configuration can be used to select which of 2 registers is addressed by variable RefPulsePos01.

| Variables in Automation Studio | I/O configuration, counter 01, option "Position sync" | |
|--|---|---|
| | Stepper counter 01 is indicated on ActPos01 . | ABR counter 01 is indicated on ActPos01 . |
| RefPulseCnt01 | Reference pulse counter for the internal position counter | Reference pulse counter of the ABR counter |
| Option "Position sync" for counter 1 also sets bit 3 in register " Counter configuration " on page 2718: | | |
| Bit 3 (counter 1) | 0 | 1 |

NetTime of the position value

Name:

ActTime01

This register contains the NetTime of the most recent valid position value.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Trigger counter

Name:

TriggerCnt01

This register contains a cyclic counter that is incremented with each trigger event.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Trigger timestamp

Name:

TriggerTime01

This register contains the NetTime instant of the most recent trigger event. The trigger edge must be configured in register "[SDC configuration](#)" on [page 2727](#).

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on [page 3035](#).

Information:

The absolute accuracy of the trigger can be delayed up to 5 µs due to the input filter of the digital inputs.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.9.16.10 Register description: Function model 254 - "Bus controller" and function model 3 - "Ramp"

9.25.9.16.10.1 Configuration registers

Holding current, nominal current and maximum current

Name:

ConfigOutput03a (holding current)

ConfigOutput04a (nominal current)

ConfigOutput05a (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

| Register | Description |
|-----------------|---|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases. In the mode " Referencing during stall ", the rated current is always used instead of the maximum current, even in acceleration phases. |
| Holding current | Current when motor is at standstill |

When the current changes to a weaker value (e.g. when transitioning from the acceleration phase to the constant speed mode), the stronger current is maintained for an additional 100 ms. The following priority applies regardless of the values actually set: maximum current before nominal current before holding current.

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 200 | Percent of the module's rated current <ul style="list-style-type: none"> • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 200% corresponds to the maximum current of the motor bridge power unit listed in the technical data. Bus controller default setting: 0 |

Full step threshold

Name:

FullStepThreshold01

Starting with the speed specified in this register, the motor is operated in full step mode; it is operated in microstep mode below it.

| Data type | Values | Information |
|-----------|------------|---|
| UINT | 1 to 65534 | Speed in microsteps/cycle. Bus controller default setting: 0 |
| | 65535 | Motor is always operated in microstep mode |

Maximum speed

Name:

MaxSpeed01pos

This register defines the maximum speed for the absolute positioning modes (1, -123, -124, -125, -126).

Information:

The setting does not apply to the speed and homing modes (2, -127, -128).

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Speed in microsteps/cycle. Bus controller default setting: 0 |

Maximum acceleration

Name:

MaxAcc01

This register defines the maximum acceleration. (also applies for homing modes).

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Acceleration in microsteps/cycle ² . Bus controller default setting: 0 |

Maximum deceleration

Name:

MaxDec01

This register defines the maximum deceleration. (also applies for homing modes).

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Brake deceleration in microsteps/cycle ² . Bus controller default setting: 0 |

Reversing loop

Name:

RevLoop01

This parameter is only used in modes 1, -123, -124, -125, -126 (absolute positioning modes).

If the value for the reversing loop is not equal to 0, the target position is approached directly when coming from one direction; when coming from the other direction, the target position is initially overshoot by the configured number of steps before finally moving to the target position. This ensures that the target position is always approached from the same direction (to avoid mechanical backlash).

The sign of the defined value determines the direction in which the reversing loop runs.

| Sign | Effective direction |
|----------|--|
| Positive | Reversing loop in positive direction of movement |
| Negative | Reversing loop in negative direction of movement |

| Data type | Values | Information |
|-----------|-----------------|-----------------------------------|
| INT | -32768 to 32767 | Bus controller default setting: 0 |

Fixed position A

Name:

FixedPos01a

This register defines the position to move to in modes -124 (if the digital input is set to 1) and -125.

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Fixed position B

Name:
FixedPos01b

This register defines the position to move to in modes [-124](#) (if the digital input is set to 0) and [-126](#).

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Homing speed

Name:
RefSpeed01

This register sets the speed for homing modes [-127](#) and [-128](#).

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Speed in microsteps/cycle. Bus controller default setting: 0 |

Stall recognition delay

Name:
StallRecognitionDelay01

The value in this register is only relevant for [Referencing during stall](#).

A stall is only detected after the time specified here has expired and after the homing procedure has started.

For example, a setting of 4 (and a cycle time of 25 ms) means that a stall will not be detected until 100 ms after the motor starts moving (start of the homing procedure).

Set to 0 to eliminate delay.

| Data type | Values | Information |
|-----------|----------|---|
| USINT | 0 to 255 | In cycles, see " General configuration " on page 2734. Bus controller default setting: 0 |

Minimum speed for stall detection

Name:
StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled. No error is reported below this threshold value.

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Minimum speed in microsteps per cycle. Bus controller default setting: 0 |

Jerk time

Name:
JoltTime01

If a value other than 0 is assigned to this register, then jerk limitation is performed. This is done by averaging the values for the steps to be carried out (speed setpoint) in each cycle using a FIFO buffer. The jerk time corresponds to the number of FIFO elements (0 to 80). If a value greater than 80 is entered, then it will be limited internally to 80.

Changes made while a motor is running will be applied as soon as ...

- The motor has reached the set position (positioning mode only).
- The motor has stopped (all modes).

| Data type | Values | Information |
|-----------|---------|---|
| USINT | 0 | No jerk limitation time. Bus controller default setting: 0 |
| | 1 to 80 | Number of FIFO elements |

Homing configuration

Name:
RefConfig01

The homing mode can be set with this register.

| Data type | Values | Information |
|-----------|------------|--|
| SINT | -120 | Set home position |
| | -121 | Homing on positive edge of input DI 4 |
| | -122 | Homing on falling edge of input DI 4 |
| | -125 | Homing on positive edge of input DI 3 (R pulse). Bus controller default setting |
| | -126 | Homing on negative edge of input DI 3 (R pulse) |
| | -127 | Homing during stall detection |
| | -128 | Immediate homing |
| | All others | No effect |

General configuration

Name:
GeneralConfig01

Bit 0 of this register can be used to switch the positioning mode. This register can also be used to configure the cycle time of the motion profile generator.

- 0: "Mode 1: Position mode" without extended control word
- 1: "Mode 1: Position mode with extended control word"

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|--|
| 0 | Position mode | 0 | Without extended control word (bus controller default setting) |
| | | 1 | With extended control word |
| 1 - 2 | Cycle time of the motion profile generator ¹⁾ | 00 | 25 ms (bus controller default setting) |
| | | 01 | 10 ms |
| | | 10 | 5 ms |
| | | 11 | Reserved |
| 3 - 7 | Reserved | 0 | |

1) The cycle time for the motion profile generator is configured with this cycle. This cycle time affects the unit for specifying the speed and acceleration:

- Unit for speed: Microsteps/Cycle
- Unit for acceleration: Microsteps/Cycle²

Limit switch configuration

Name:

LimitSwitchConfig01

This register configures the behavior of the limit switches.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------|-------|---|
| 0 - 1 | Negative limit switch | 00 | Switched off (bus controller default setting) |
| | | 01 | Active if low |
| | | 10 | Reserved |
| | | 11 | Active if high |
| 2 - 3 | Positive limit switch | 00 | Switched off (bus controller default setting) |
| | | 01 | Active if low |
| | | 10 | Reserved |
| | | 11 | Active if high |
| 4 - 6 | Reserved | 0 | |
| 7 | Direction monitoring | 0 | Off (bus controller default setting) |
| | | 1 | On |

Negative/Positive limit switch:

When one of the limit switches is reached, a warning is triggered and the speed is decelerated to 0. There is no state change of "Device control state machine". This keeps current flowing to the motor.

The error that occurred can be read from the error code register. Normal operation can be resumed by acknowledging the warning. This will not restrict motor movement to a specific direction and the limit switch will not be triggered until the next active edge.

Overshooting the limit switch while braking

The limit switches are not linked with the corresponding direction of movement. If the limit switch is exceeded, another error will be triggered when reversing after acknowledging the initial error.

Direction monitoring

If this function is enabled, then the two limit switches will be linked with the respective direction of movement. This means that the negative limit switch is only triggered in the negative and the positive limit switch only in the positive direction of movement (specified direction).

This prevents specifying a movement in the wrong direction when direction monitoring is enabled and limit switches are active.

Warning!

If the motor is wired incorrectly with this configuration (wrong direction of movement), then the limit switch will not be triggered and the actual correct direction of movement will be denied. This will also be the case when the limit switch connections are reversed.

Software limit

Name:

PositionLimitMin01

PositionLimitMax01

This register configures software limits. The function is enabled if at least one of the two registers is not equal to zero.

These limits are effective in all positioning modes. Position overflow is not possible when this function is enabled. Movement is always contained within the two limits.

If a position is specified that violates the minimum/maximum software limit, the "Internal limit active" bit will be set in the "Status word" on page 2743 register. The motor movement will be stopped until a position is specified within the limits.

Bit "Internal limit active" will also be set in register "Status word" if incorrectly configured (minimum > maximum).

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Information:

The software limits will only be monitored when using the following CANopen bus controllers:

- X20BC0043-10
- X20BC0143-10
- X67BC4321-10
- X67BC4321.L08-10
- X67BC4321.L12-10

9.25.9.16.10.2 Reading back the configuration

Reading back the holding current, nominal current and maximum current

ConfigOutput03aRead (holding current)

ConfigOutput04aRead (nominal current)

ConfigOutput05aRead (maximum current)

These registers are used to read the respective current values in percent.

| Register | Description |
|-----------------|--|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases |
| Holding current | Current when motor is at standstill |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 255 | Percentage of module's nominal current (100% corresponds to the nominal current of the motor bridge power unit in the technical data) |

9.25.9.16.10.3 Communication registers

Measuring motor load

Name:

MotorLoad

This register contains the current measured load value for stall detection. A high value indicates a small load on the motor; the lower the value, the higher the motor load. The SGT values (see "SGT speed" on page 2714 and "SGT correction values" on page 2714) should be set so that the motor load returns value 0 at maximum load (shortly before stall).

This register can be shown and hidden via the module configuration.

| Data type | Values |
|-----------|-----------|
| UINT | 0 to 1023 |

Set position/speed

Name:
AbsPos01

This register is used to set position or speed, depending on the operating mode.

- Position mode (see "Mode" on page 2738): Cyclic setting of the position setpoint in microsteps. In this mode, one micro-step is always 1/256 full-step.
- Speed mode (see "Mode" on page 2738): In this mode, this register is considered a signed speed setpoint.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Control word

Name:
MpGenControl01

This register can be used to issue commands based on the module's state (see "Operating function model "Ramp"" on page 2746).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|-------|--|
| 0 | Switch on | x | |
| 1 | Enable voltage | x | |
| 2 | Quick stop | x | |
| 3 | Enable operation | x | |
| 4 - 6 | Mode-specific | x | |
| 7 | Fault reset | x | |
| 8 | Stop ¹⁾ | x | |
| 9 | CurrentControlEnable | 0 | Disable load-dependent current control |
| | | 1 | Enable load-dependent current control |
| 10 | Reserved | 0 | |
| 11 | Motor ID trigger | 0 | No effect |
| | | 1 | Rising edge: Motor ID trigger ²⁾ |
| 12 | Warning reset | 0 | No effect |
| | | 1 | Rising edge: Reset warnings |
| 13 | Undercurrent detection | 0 | Disable current error detection (default) |
| | | 1 | Enable current error detection |
| 14 | ABR counter sync/async | 0 | Default: <ul style="list-style-type: none"> • Internal position counter, cyclic • ABR counter, acyclic |
| | | 1 | <ul style="list-style-type: none"> • Internal position counter, acyclic • ABR counter, cyclic |
| 15 | Stall detection | 0 | Disable stall detection (default) |
| | | 1 | Enable stall detection |

1) The "Stop" bit is only evaluated when the extended control word is enabled (see "General configuration" on page 2734).

2) This bit can be used to trigger a measurement of the motor ID. Keep in mind that the application must ensure that the conditions for measurement are fulfilled (see table in the "Motor identification" on page 2744 register).

Mode

Name:

MpGenMode01

| Data type | Values | Information |
|-----------|--------|---|
| SINT | 0 | No mode selected |
| | 1 | Depending on bit 0 in the "General configuration" on page 2734 register, the position mode will behave as follows: <ul style="list-style-type: none"> Position mode without extended control word: Move to target position as soon as the target position is changed Position mode with extended control word: Move to the target position as described in "Mode 1 - Position mode with extended control word" on page 2738 |
| | 2 | Speed mode: Constant speed |
| | -120 | Set home position |
| | -121 | Remaining distance mode |
| | -122 | Set actual position |
| | -123 | Move to target position when external input set |
| | -124 | Two-position module |
| | -125 | Move to fixed position A (position set acyclically) |
| | -126 | Move to fixed position B (position set acyclically) |
| | -127 | Positive homing (see also "Homing configuration" on page 2734) |
| | -128 | Negative homing (see also "Homing configuration" on page 2734) |

Information:

For all modes: The "Target reached" bit is set in the "Status word" on page 2743 register when the current action is finished (i.e. when the position or speed is reached, depending on the mode).

A new position or speed can be specified even before the current action is finished.

Mode 1 - Position mode

The position setpoint is specified in the "Set position/speed" on page 2737 register. The motor is then moved to this new position. This is done with a ramp function that accounts for the defined maximum speed and acceleration values.

The position setpoint can also be changed during an active positioning procedure.

The position setpoint is specified in microsteps (1/256 of a full step).

If bit 0 in the "General configuration" on page 2734 register is 0 (no extended control word), then the position setpoint will be applied as soon as it is different from the current position. Then the new position is used for the movement.

However, if bit 0 in the "General configuration" on page 2734 register is set to 1 (extended control word), then the position setpoint will be applied as described under "Mode 1 - Position mode with extended control word" on page 2738.

Mode 1 - Position mode with extended control word

Position mode with extended control word behaves like [Position mode 1](#) as described previously (without the extended control word), but the new position setpoint ("Position/Speed" on page 2737 register) is applied according to the [extended control word](#).

Extended control word

Commands can be issued using this register depending on the state of the module (see "Operating function model "Ramp"" on page 2746).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|---|
| 0 - 3 | Corresponds to the default Control word | x | |
| 4 | New setpoint | 0 | Do not apply target position. |
| | | 1 | Apply target position. |
| 5 | Change set immediately | 0 | Complete current positioning movement and then start next positioning movement |
| | | 1 | Interrupt current positioning movement and then start next positioning movement |
| 6 | abs / rel | 0 | Target position is an absolute value. |
| | | 1 | Target position is a relative value. |
| 7 | Corresponds to the default Control word | x | |
| 8 | Stop ¹⁾ | 0 | Execute positioning |
| | | 1 | Stop axis with deceleration |
| 9 - 15 | Corresponds to the default Control word | x | |

1) This bit applies to all modes.

Extended status word

The bits in the status word reflect the status of the state machine (for a detailed description, see "Status word" on page 2747 and "State machine" on page 2748).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|-------|---|
| 0 - 9 | Corresponds to the default Status word | x | |
| 10 | Target reached, depending on bit 8 (Stop) in the Control word register | 0 | If Stop = 0 |
| | | | Target position not reached. |
| | | 1 | Target position reached |
| | | | If Stop = 1 |
| | | 0 | Axis decelerating |
| | | 1 | Axis speed = 0 |
| 11 | Corresponds to the default Status word | x | |
| 12 | Setpoint acknowledge | 0 | Ramp generator did not apply the position value |
| | | 1 | Ramp generator applied the position value |
| 13 - 15 | Corresponds to the default Status word | x | |

Position setting

The target position can be defined in 2 different ways:

| Type of setpoint definition | Description |
|-----------------------------|---|
| Single setpoint | After the target position is reached, Bit <i>Target reached</i> in register " Status word " on page 2743 is set. Then a new target position is defined. The drive stops at each target position before starting the movement to the next target position. |
| Set of setpoints | After the target position has been reached, the movement to the next target position is started immediately without stopping the drive. It is therefore possible to initiate a new positioning by specifying another target position during active positioning. |

The two modes "Single setpoint" and "Set of setpoints" are controlled by the timing of bits *New setpoint* and *Change set immediately* in the "[extended control word](#)" on page 2739 and *Setpoint acknowledge* in register "[Extended control word](#)" on page 2739.

These bits can be used to create a Request-Response mechanism. This makes it possible to specify a target position while a previous position specification is still being processed.

Specifying the target position

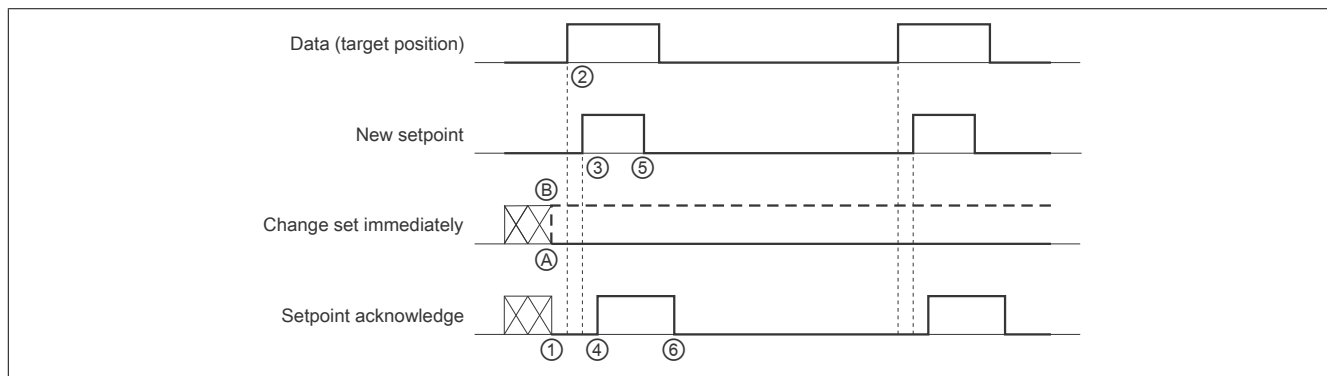

Figure 189: Principle for applying the setpoint

Transferring a new setpoint:

- 1) If bit *Setpoint acknowledge* in register "Extended status word" on page 2739 is 0, the module will accept a new target position.
- 2) The new target position is specified in register "Set position/speed" on page 2737.
- 3) A rising edge on bit *New setpoint* in the "extended control word" on page 2739 indicates that the new target position in register "Set position/speed" on page 2737 is valid and can be used for the next positioning movement.
- 4) After the module has received and saved the new target position, bit *Setpoint acknowledge* is set to 1 in register *Status word*.
- 5) Now the controller can reset the *New setpoint* bit to 0.
- 6) Then the module resets bit *Setpoint acknowledge* to 0 to signal when a new target position is accepted.

Position specification "Single setpoint"

When the *Change set immediately* bit is set to 0 (A in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This mechanism results in a speed of 0 when the motor reaches target position x_1 at time t_1 . After the controller has been notified that the setpoint has been reached, the next target position x_2 will be processed at time t_2 and reached at t_3 .

Figure 190: Ramp in *Single setpoint*

"Set of setpoints" preset position value

When the *Change set immediately* bit is set to 1 (B in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This means that the module receives the first target position at t_0 . A second target position is received at time t_1 . The drive immediately adapts the current movement to the new target position.

Figure 191: Ramp in *Set of setpoints*

Relative position setting

If bit *abs / rel* bit in register [Extended control word](#) is set, then the target position is interpreted as a relative value. At each *New setpoint* trigger, the target position will be increased by this value (or decreased if the value is negative).

If the mode changes between the position settings, relative movement will then proceed starting at the last specified position. The position setpoint mode is initialized with 0 when the module is started.

Mode 2: Speed mode - Constant speed (pos./neg.)

The value in register ["Position/Speed" on page 2737](#) is now interpreted as the speed setpoint (microsteps/ *cycle*).

Observing the maximum permissible acceleration, the motor moves with a ramp to the desired speed setpoint and maintains this speed until a new speed setpoint is specified.

Values are allowed within the range -65535 to 65535. When a value is entered outside of this range, it is readjusted to these limits.

Mode -120: Set home position

The current actual position is changed so that the position specified in register ["Position/Speed" on page 2737](#) is the home position. If you then move to this position, the motor is at the home position.

The home position in register ["Home position" on page 2744](#) is also set to this value.

Before this mode is called, the motor must be at a standstill and the home position must have been determined using ["Positive / negative homing"](#) mode. In order to set the position, the [State machine](#) must be in state "Operation enable".

Mode -121: Remaining distance mode (like mode 1)

The number of steps defined in register ["Fixed position A" on page 2732](#) are added to the current position and the resulting position is approached at a rising/falling edge on digital input 3.

Advice:

Steps are not added to the target position, but rather to the current position at the moment the trigger occurs.

Negative values are also allowed for the offset defined in [Fixed position A](#).

New target positions are no longer accepted in register ["Position/Speed" on page 2737](#) after the trigger event. There must first be a switch made to [mode 0](#) and then back to mode -121.

Bit "Target reached" in register ["Status word" on page 2743](#) is not set to 1 until the end position (after the trigger event) has been reached.

The ["homing configuration" on page 2734](#) determines whether a rising or falling edge of the digital input is used as a trigger.

The [Reversing loop](#) is not enabled in this mode (i.e. any configured values not equal to 0 are ignored).

Mode -122: Set actual position

The target position set in register ["Position/Speed" on page 2737](#) is applied as the current actual position in the internal position counter if the state machine is in state "Operation enable".

Before this mode is started, the motor must be at a standstill and physically located at the point for which the position being set should be applied.

Mode -123: Move to the target position when the external input is set

The position setpoint set in register ["Position/Speed" on page 2737](#) is moved on a rising edge of digital input 3.

A new position setpoint is not applied until another rising edge occurs on the corresponding digital input. This can also occur during the active positioning procedure and will be applied immediately.

Mode -124: Two-position mode

Positions [Fixed position A](#) and [Fixed position B](#) are defined in the acyclic registers.

Value 1 on digital input 3 moves to fixed position A. Value 0 moves to fixed position B. It is also possible to switch between the two during an active positioning movement.

Mode -125/-126: Move to fixed position X

The purpose of these modes is to enable a virtual switch from speed mode to position mode, which otherwise is not possible because of the shared use of the register for position and speed setpoints.

- Mode -125: "Fixed position A" on page 2732
- Mode -126: "Fixed position B" on page 2733

Mode -127/-128: Positive/Negative homing

Mode -127 and -128 are used to select which direction to move.

The motor must be at a standstill before switching from another mode to one of the homing modes.

If the referencing condition occurs, then the motor stops and the values of the position counter and ABR counter valid at the moment when the referencing condition occurs are written to the "Referenced zero position" on page 2744 register.

In the [referencing configuration](#) you must specify whether referencing should occur at low/high level on the digital input, during stall or unconditionally.

Homing via digital input

Case 1: Active referencing level not yet reached → Motor not yet at end position:

Movement continues at the referencing speed in the referencing direction until the active level for "Stop referencing" is on the input.

Case 2: Active referencing level already reached → Motor at end position:

Movement continues at the referencing speed against the referencing direction until the active level for "Stop referencing" is no longer at the digital input. Movement continues at homing speed in the homing direction until the active level for "homing-stop" is on the digital input again.

Referencing during stall

Movement continues in the referencing direction until a stall is detected. When a stall is detected, the value of the position counter is entered in the "Referenced zero position" on page 2744 register within one millisecond. The motor is then stopped abruptly (not using the deceleration ramp). However, it can take up to 25 ms to stop the motor because the ramp generator runs with a configurable internal cycle of up to 25 ms.

In this mode, the nominal current is always used instead of the maximum current, even in acceleration phases.

To test the responsiveness of this homing mode, the motor load value used for identifying a stall can be made visible in the status word.

Unconditional referencing (immediate)

Immediate referencing: The current values of the position counter and of the ABR counter are immediately entered in register "Homed zero position" on page 2744, no motor movement.)

Current position (cyclic)

Name:

AbsPos01ActVal

This cyclic register contains the current position.

Default: Value of the internal position counter, can be changed to ABR counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Status word

Name:

MpGenStatus01

The bits in this register reflect the state of the state machine. For a more detailed description, see "[Status word](#)" on page 2747 and "[State machine](#)" on page 2748.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|-----------------------|-------|---|
| 0 | Ready to switch on | x | |
| 1 | Switched on | x | |
| 2 | Operation enabled | x | |
| 3 | Fault (error bit) | x | |
| 4 | Voltage enabled | x | |
| 5 | Quick stop | x | |
| 6 | Switch on disabled | x | |
| 7 | Warning | x | |
| 8 | Reserved | 0 | |
| 9 | Remote | 1 | Always 1 since there is no local mode for the SM module |
| 10 | Target reached | x | |
| 11 | Internal limit active | 0 | No limit violation |
| | | 1 | Internal limit is active (upper or lower software limit violated) |
| 12 | Mode-specific | x | |
| 13 - 15 | Reserved | 0 | Always 0 |

Input status

Name:

InputStatus

This register indicates the logical states of digital inputs.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------|--------|---------------------------------|
| 0 | Digital input 1 | 0 or 1 | Input state - Digital input 1 |
| ... | | ... | |
| 3 | Digital input 4 | 0 or 1 | Input state - Digital input 4 |
| 4 | Open circuit 1 | 0 | No error |
| | | 1 | Open circuit on digital input 1 |
| ... | | ... | |
| 7 | Open circuit 4 | 0 | No error |
| | | 1 | Open circuit on digital input 4 |

Motor identification

Name:

Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. After successful measurement, this register contains the time [µs] required to apply a current increase of $\Delta I = 1 \text{ A}$ to a motor winding.

This depends on:

- Operating voltage
- Inductance and resistance of the motor winding

| Notes | |
|-------|---|
| 1) | To achieve reproducible results, the measurement must be made under the following defined conditions: |
| a) | Motor is at standstill. |
| b) | The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: <ul style="list-style-type: none"> • Full steps are divisible by 4. • Microsteps = 0 |
| 2) | Condition 1b) is fulfilled after a the SM module is reset or switched on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application. |
| 3) | The current range from approximately 1/3 of the nominal current up to the nominal current is used as operating range for determining the motor identifier. |

| Data type | Motor ID values | Explanation |
|-----------|-----------------|--|
| UINT | 0 | No motor identifier available (after switching on for as long as the measurement conditions are not met) |
| | 1 to 32767 | Valid range of values for the motor ID register (in µs) |
| | 65534 | Invalid value: Overflow |

Homed zero position

Name:

RefPos01CyclicCounter

RefPos01AcyclicCounter

After a homing procedure, the homing point for the cyclic or acyclic position counter can be read back with these registers (either the internal position counter or ABR counter depending on bit 14 of register "[Control word](#)" on [page 2737](#)).

The following two registers are provided for the motor:

- Homed zero position for cyclic counter
- Homed zero position for acyclic counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Current position (acyclic)

Name:

AbsPos1ActValAcyclic

This acyclic register contains the current position.

Default: Value of the ABR counter, can be changed to internal position counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Read back control word

Name:

ControlReadback01

This register can be used to read the contents of register "[Control word](#)" on [page 2737](#).

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Read back mode

Name:

ModeReadback01

This register can be used to read the contents of register "Mode" on page 2738.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Error code

Name:

ErrorCode01

The cause of an error or warning can be read in this register.

| Data type | Error code | Error type | Priority | Description |
|-----------|------------|------------|----------|-----------------------------|
| UINT | 0x0000 | - | - | No error |
| | 0x3000 | Error | High | Voltage |
| | 0x4200 | Error | : | Overtemperature |
| | 0xFF20 | Warning | : | Negative limit switch |
| | 0xFF21 | Warning | : | Positive limit switch |
| | 0x2300 | Warning | : | Overcurrent |
| | 0xFF00 | Warning | : | Current error ¹⁾ |
| | 0xFF01 | Warning | : | Stall ²⁾ |
| | 0xFF11 | Warning | Low | Open circuit |

1) A current error is only detected if bit 13 = 1 in the [control word](#) (current error detection enabled).

2) Stall is only detected if bit 15 = 1 in the [control word](#) (stall detection enabled).

Information regarding the handling of errors and warnings:

- Bit 3 (fault) and bit 8 (warning) in the [status word](#) can be used to query whether an error or a warning was reported in the error code register.
- Bit 7 (Fault Reset) and bit 8 (Warning Reset) in the [control word](#) are used to acknowledge pending errors and warnings.
- If two or more errors/warnings are pending, the one with the highest priority (the order in the table above) will be displayed in the error code register.

9.25.9.16.10.4 Operating function model "Ramp"

Control for this model has been based on the CANopen communication profile DS402.

Commands for controlling the modules are written to the "Control word" on page 2746. The current module state is returned in register "Status word" on page 2747. The function mode (absolute position, constant speed, homing, etc.) is set in register "Mode" on page 2738.

Control word

Control word bits and their state for the commands of the state machine:

| Command | Stall detection | Encoder position sync/async | Current error detection | Warning reset | Motor ID trigger | Reserved | CurrentControlEnable | Stop 2) | Fault reset | Mode-specific | Mode-specific | Mode-specific | Enable operation | Quick stop | Enable voltage | Switch on |
|-------------------|-----------------|-----------------------------|-------------------------|---------------|------------------|----------|----------------------|---------|-------------|---------------|---------------|---------------|------------------|------------|----------------|-----------|
| Bit ¹⁾ | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Shutdown | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 1 | 1 | 0 |
| Switch on | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | 0 | 1 | 1 | 1 |
| Disable voltage | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | x | 0 | x |
| Quick stop | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 0 | 1 | x |
| Disable operation | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 0 | 1 | 1 |
| Enable operation | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | 1 | 1 | 1 | 1 |
| Fault reset | x | x | x | x | x | 0 | 0 | x | ↑ | x | x | x | x | x | x | x |

1) x ... Any, ↑ ... Rising edge

2) Bit 8 (stop) is only evaluated if the extended control word is enabled in register "General configuration" on page 2734.

| | |
|---|--|
| Bits 0, 1, 2, 3 and 7 (light gray in the previous table) | These bits control the state of the State machine according to the commands in the table above. |
| Stop | 0 ... Perform motor movement 1 ... Stop axis with deceleration This bit is only evaluated when the extended control word is enabled in register "General configuration" on page 2734. |
| Motor ID trigger | A rising edge enables the motor ID measurement. |
| Warning reset | A rising edge resets warnings (no effect on errors, which are reset using "Fault reset"; the state machine is not affected by this bit). |
| Fault reset | A rising edge resets errors and warnings (see "State machine" on page 2748) |
| Current error detection | 0 ... Current error detection disabled 1 ... Current error detection enabled |
| ABR counter sync/async | 0 ... Value of the ABR counter on register "Current position (acyclic)" on page 2744. Internal position counter of the ramp generator on register "Current position (cyclic)". 1 ... Value of the ABR counter on register "Current position (cyclic)" on page 2742. Internal position counter of the ramp generator on register "Current position (acyclic)". |
| Stall detection | 0 ... Stall detection disabled 1 ... Stall detection enabled |
| CurrentControlEnable | 0 ... Load-dependent current control disabled 1 ... Load-dependent current control enabled |

Status word

The individual bits of this register and its states depend on the current state of the state machine:

| Status | Reserved | Reserved | Reserved | Reserved | Int. limit active | Target reached | Remote | Reserved | Warning | Switch on disabled | Quick stop | Voltage enabled | Fault | Operation enabled | Switched on | Ready to switch on |
|------------------------|----------|----------|----------|----------|-------------------|----------------|--------|----------|---------|--------------------|------------|-----------------|-------|-------------------|-------------|--------------------|
| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Not ready to switch on | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 0 | 0 | 0 | 0 |
| Switch-on disabled | x | x | x | x | x | x | 1 | 0 | x | 1 | x | 0 | 0 | 0 | 0 | 0 |
| Ready to switch on | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 0 | 0 | 0 | 0 | 1 |
| Switched on | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 1 | 0 | 0 | 1 | 1 |
| Operation enable | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 1 | 0 | 1 | 1 | 1 |
| Quick stop active | x | x | x | x | x | x | 1 | 0 | x | 0 | 0 | 1 | 0 | 1 | 1 | 1 |
| Fault reaction active | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 1 | 1 | 1 | 1 |
| Fault | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 1 | 0 | 0 | 0 |

Information about the status word:

| | | |
|---|--|--|
| Bits 0, 1, 2, 3, 5 and 6 (light gray in the previous table) | These bits are set according to the current state of the State machine . | |
| Voltage enabled | Becomes 1 as soon as the motor is powered | |
| Warning | Becomes 1 if a warning is detected ("Overcurrent", "Undercurrent"). The type of warning is indicated in register " Error code " on page 2745. The highest priority error / warning is shown in each case, with the priority corresponding to the order in the respective table. Warnings can be reset with a rising edge on the "Warning reset" bit in the control word. | |
| Remote | Always 1 since there is no local mode on the SM module | |
| Target reached ¹⁾ , depending on bit 8 (Stop) in register Control word | <p>If Stop = 0</p> <p>In modes 1, -123, -124, -125 and -126 (absolute positioning): 0...Positioning begins 1...Target has been reached</p> <p>In mode 2 (constant speed): 0...Motor accelerates/brakes 1...Speed setpoint reached</p> <p>In modes -127 and -128 (homing): 0...Homing started 1...Homing ended</p> <p>In mode -122 (set actual position): The bit briefly becomes 0 and immediately becomes 1 again as soon as the position is set.</p> | <p>If Stop = 1</p> <p>In all modes: 0...Axis decelerating 1...Axis speed = 0</p> |
| Internal limit active | 0 ... No limit violation 1 ... Internal limit is active (upper/lower software limit violated) | |

1) If "Stop" has not been enabled in register "[General configuration](#)" on page 2734, then "Target reached" behaves the same as if Stop = 0.

State machine

The motor is controlled according to the state machine illustrated below. After the module is started, the state machine automatically changes to state "Not ready to switch on". The application then operates the state machine by writing commands to the [Control word](#).

The state machine successively reaches the states "Ready to switch on", "Switched on" and "Operation enable" by writing the consecutive commands "Shutdown", "Switch on" and "Enable operation".

Information:

Only in state "Operation enable" are motor movements executed according to the setting in register "Mode" on page 2738.

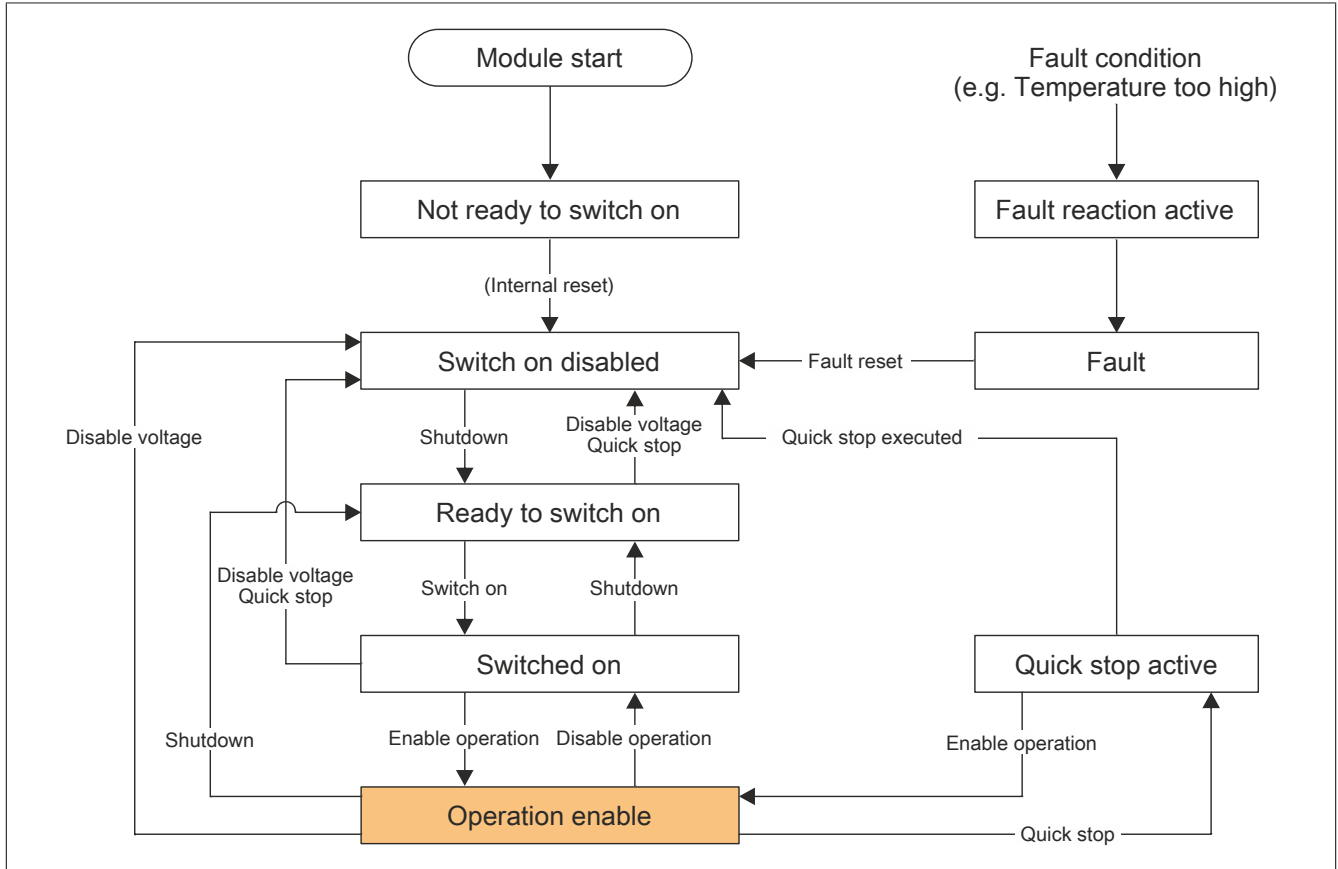

Figure 192: State machine - Flow chart

| State change | Description |
|--|--|
| Not ready to switch on → Switch on disabled | This state change occurs automatically after starting the module and internal initialization has taken place. |
| Switch-on disabled → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . No others actions are performed. |
| Ready to switch on → Switch-on disabled | This state change is brought on by the command <i>Disable voltage</i> or <i>Quick stop</i> . No others actions are performed. |
| Switched on → Switch-on disabled | This state change is brought on by the command <i>Disable voltage</i> or <i>Quick stop</i> . The motor voltage is cut off immediately. |
| Ready to switch on → Switched on | This state change is brought on by the <i>Switch on</i> command. The motor voltage is switched on. When this state change occurs for the first time since the module is started, the motor ID measurement is performed before state <i>Switched on</i> is achieved. This can take approximately 1 second. |
| Switched on → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . The motor voltage is cut off immediately. |
| Switched on → Operation enable | This state change is brought on by the <i>Enable operation</i> command. Motor movements are now performed depending on the set mode. |
| Operation enable → Switched on | This state change is brought on by the <i>Disable operation</i> command. If in motion, the motor is decelerated with the configured braking deceleration. The motor voltage remains switched on in state <i>Switched on</i> . |
| Operation enable → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . The motor voltage is cut off immediately. |
| Operation enable → Switch on disabled | This state change is brought on by the <i>Disable voltage</i> command. Motor voltage switched off. It is strongly recommended to only make this state change on a stopped motor since regeneration on a motor running at no load can cause an overvoltage error on the DC bus (0x3210). |
| Operation enable → Quick stop active | This state change is brought on by the <i>Quick stop</i> command. If in motion, the motor is decelerated with the configured braking deceleration. During the deceleration, the state machine remains in state <i>Quick stop active</i> . If the motor comes to standstill, the switch to state <i>Switch on disabled</i> takes place automatically. While the state machine is in state <i>Quick stop active</i> , command <i>Enable operation</i> can be used to switch it back to state <i>Operation enable</i> . |
| → Fault reaction active | This state change is brought on when an error occurs and cannot be triggered by a command from the user. It can be triggered by error types classified as an "Error" (see "Error code" on page 2745). (The other error types classified as "Warning" only cause the "Warning" bit to be set in the status word and do not cause a state change of the state machine.) The motor voltage is cut off and the state machine immediately changes to state <i>Fault</i> . The error code register contains the error type (see table in "Error code" on page 2745). The highest priority error is shown. The priority corresponds to the order in the error code table. |
| Fault → Switch-on disabled | This state change is brought on by the <i>Fault reset</i> command. However, the state only changes if no more errors are present when the command is written. All errors and warnings are reset. The error code register contains 0 or the warning code if a warning is still present. |

Table 524: State machine - State change

9.25.9.16.11 NetTime Technology

For a description of NetTime Technology, see ["NetTime Technology" on page 3035](#).

9.25.9.16.12 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|---------------------------|--------|
| Function model "Standard" | 400 µs |
| Function model "Ramp" | 400 µs |

9.25.9.16.13 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|---------------------------|--------|
| Function model "Standard" | 400 µs |
| Function model "Ramp" | |
| Inputs | 400 µs |
| Outputs ¹⁾ | 25 ms |

1) Depends on the configuration of the ["movement profile generator" on page 2734](#).

9.25.10 X20SM1446-1

Data sheet version: 1.26

9.25.10.1 General information

The stepper motor module is used to control stepper motors with a nominal voltage of 24 to 48 VDC ($\pm 25\%$) at a motor current up to 5 A (10 A peak). In addition, this module has 4 digital inputs that can be used as limit switches or encoder inputs.

Due to the individual adjustment of the coil currents, the motor is only operated with the current it actually needs. This simplifies the selection of the available motors and prevents unnecessary heating. Because this affects energy consumption and thermal load, the effects are positive on the service life of the complete system. Complete flexibility is achieved through the use of independently adjustable holding, maximum and nominal current values. The current for microsteps is automatically adjusted to the configured current values.

In addition, the module contains a sensorless, load-dependent current control. Depending on the operating situation and load, the module controls the current downwards. Energy savings up to 75% are possible in this way.

The automatic motor identification system is an enormous help during standstills. The stepper motor modules can identify the connected motors using their coil characteristics and generate feedback in the form of an analog value. This makes it possible to detect not only wiring errors, but also incorrect motor types being used mistakenly. A stall detection mechanism is integrated to analyze the motor load. Detection of the stall is defined via a configurable threshold. This allows an overload or motor standstill to be detected precisely in many different types of applications.

- 1 stepper motor, 24 to 48 VDC $\pm 25\%$, 5 A (10 A peak)
- Resolution of current values at 1%
- Boost, nominal and holding current separately configurable
- Sensorless, load-dependent current control
- Integrated motor detection
- 256 microsteps per step
- Stall detection
- Complete integration in Automation Studio and CNC applications
- 4 inputs, 24 VDC, adjustable for ABR incremental encoders
- Open circuit detection for push-pull encoders
- Input ramp limit at max. 12.5 A
- Function model "Ramp" based on CANopen communication profile DS402

NetTime timestamp of the position and trigger time

It is not just the position value that is important for highly dynamic positioning tasks, but also the exact time the position is measured. The module is equipped with a NetTime function for this that supplies a timestamp for the recorded position and trigger time with microsecond accuracy.

The timestamp function is based on synchronized timers. If a timestamp event occurs, the module immediately saves the current NetTime. After the respective data is transferred to the CPU, including this precise moment, the CPU can then evaluate the data using its own NetTime (or system time), if necessary.

9.25.10.2 Order data

| Model number | Short description | Figure |
|--------------|---|---|
| | Motor controllers |  |
| X20SM1446-1 | X20 stepper motor module, module power supply 24 to 48 VDC $\pm 25\%$, with current reduction function, 1 motor connection, 5 A continuous current, 10 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder, NetTime function, double-width module | |

1) See section "Let-through energy I2T".

9.25.10.4 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

| Figure | LED | Color | Status | Description |
|---|-------|--------|--------------------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | Mode RESET |
| | | | Double flash | Mode BOOT (during firmware update) ¹⁾ |
| | | | Blinking | Mode PREOPERATIONAL |
| | | | On | Mode RUN |
| | e | Red | Off | Module not supplied with power or everything OK |
| | | | On | Error or reset status |
| | e + r | | Solid red / Single green flash | Invalid firmware |
| | 1 - 4 | Green | On/Off | Input state of the corresponding digital input |
| | | | Blinking | Open circuit or not connected |
| M | | Orange | On | The motor is active. |

1) Depending on the configuration, a firmware update can take up to several minutes.

9.25.10.5 Pinout

Per standard EN 60204-1, a cable cross section of 0.75 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 5 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

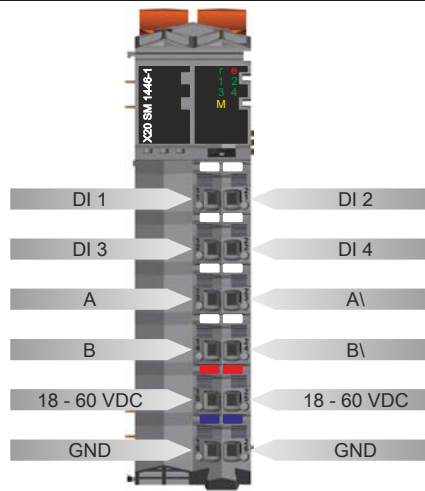

The terminal block is not permitted to be plugged in or unplugged during operation.

Information:

Shielded motor cables must be used in order to meet the limits per standard EN 55011 (emissions).

Information:

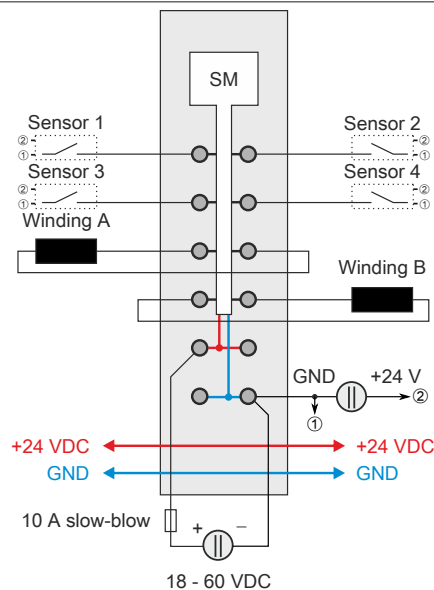

If a boot current of 10 A is required, the motor cables are not permitted to be longer than 2 meters.

9.25.10.6 Connection example

Information:

This module can only be operated if supplied with power via the terminal block.

For the wiring of sensors 1 to 4 see ["Push-pull input circuits" on page 2754](#)

9.25.10.6.1 Push-pull input circuits

The digital inputs of the module are equipped with open-circuit detection and therefore designed for push-pull circuits.

Information:

If no push-pull circuit is used, an open sensor contact is interpreted by the module as an open circuit.

Circuit variants

The size of the resistor depends on the sensor used and must therefore be calculated in each individual case.

9.25.10.7 Connection options for digital inputs

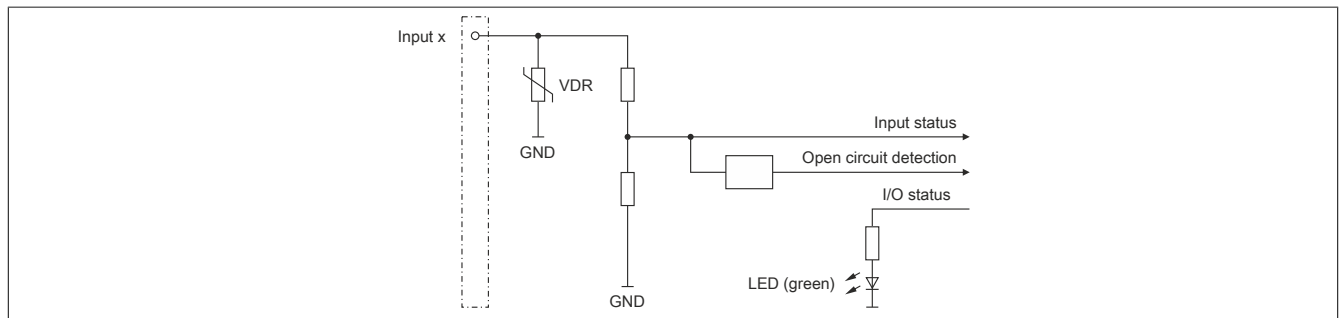

Function model "Standard"

| Channel | Function | |
|---------|---------------|---------------|
| DI 1 | Digital input | A |
| DI 2 | Digital input | B |
| DI 3 | Digital input | R |
| DI 4 | Digital input | Trigger input |

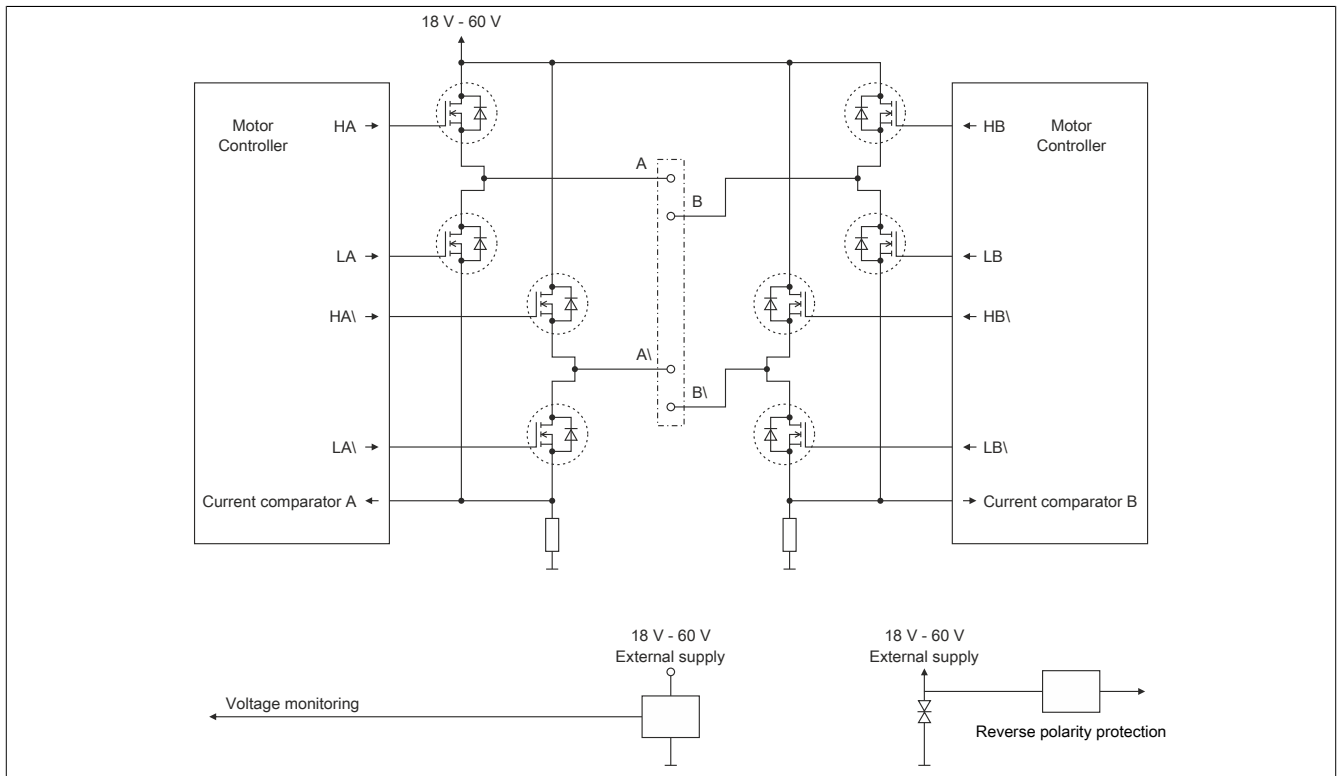

Function model "Ramp"

| Channel | Function | | |
|---------|---------------|---------------|-----------------------|
| DI 1 | Digital input | A | A |
| DI 2 | Digital input | B | B |
| DI 3 | Digital input | R | Negative limit switch |
| DI 4 | Digital input | Digital input | Positive limit switch |

9.25.10.8 Input circuit diagram

9.25.10.9 Output circuit diagram

9.25.10.10 Motor cutoff in the event of overvoltage

The module power supply voltage is continually monitored. Its status can be read. Error "[Module power supply error](#)" is reported if the voltage is greater than or less than the limit values.

If the supply voltage in the module overshoots or undershoots the limit values (e.g. during regenerative operation), the motor output is cut off!

If the supply voltage is within the permissible range again, the error must first be [acknowledged](#). The output stage can then be switched on again.

Limit values for the supply voltage

| | Drive cut off | Drive switched back on |
|-------------|---------------|------------------------|
| Lower limit | <17.4 V | >17.8 V |
| Upper limit | >60.3 V | <58.6 V |

9.25.10.11 Shutdown in the event of overtemperature (starting at 116°C)

If the module temperature reaches or overshoots the limit value of 116°C, the module performs the following actions:

- Sets the "overtemperature" error bit
- Cuts off the outputs (short-circuited)

As soon as the temperature is reduced below 116°C again, the error must be acknowledged with "OvertemperatureAcknowledge" so that the channels can be switched on again.

9.25.10.12 Power supply dimensioning

The motor's current consumption depends on the defined motor currents, the available power and the actual motor being used.

| Example | |
|--|-------------------|
| Model number of the motor | 80MPD5.300S000-01 |
| Configured current in the motor module | 3 A |
| Supply voltage of the motor module | 48 VDC |
| Motor load | 1 Nm |

Table 527: Power supply dimensioning example - Basic data

Figure 193: Power supply dimensioning example - Power/Speed relationship

The example is based on a constant load throughout the entire speed range.

An increase in the motor load causes an increase in the effective current of the I/O power supply.

9.25.10.13 Fuse protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load but is always less than the motor current. Make sure the maximum nominal current of 10 A is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the mains power input and the rated current of the used fuse are chosen according to the current-carrying capacity such that the permissible current-carrying capacity of the selected cable cross section (depending on wiring, see table) is greater than or equal to the current load in the mains power input. The rated current of the fuse protection must be less than or equal to the permissible current-carrying capacity of the selected cable cross section (depending on the how it is installed, see table):

$$I_{\text{Power system}} \leq I_{\text{Fuse}} \leq I_{\text{Line/cable}}$$

| Wire cross section [mm ²] | Current-carrying capacity of cable cross section I_z / rated current of fuse I_b [A] depending on the to type of wiring at an ambient air temperature of + 40°C per EN 60204-1 | | | |
|---------------------------------------|--|-----------|-----------|-----------|
| | B1 | B2 | C | E |
| 1.5 | 13.5 / 13 | 13.1 / 10 | 15.2 / 13 | 16.1 / 16 |
| 2.5 | 18.3 / 16 | 16.5 / 16 | 21 / 20 | 22 / 20 |

Table 528: Cable cross section of the mains power input depending on the type of wiring

The tripping current of the fuse is not permitted to exceed the rated current of the fuse I_b .

| Type of wiring | Description |
|----------------|--|
| B1 | Wires in conduit or cable duct |
| B2 | Cables in conduit or cable duct |
| C | Cables or wires on walls |
| E | Cables or wires on open-ended cable tray |

Table 529: Type of wiring used for the mains power input

9.25.10.14 Let-through energy I²T

The module is designed for a continuous current of 5 A. A higher current can be temporarily drawn, however. The following points must be observed:

- The module is designed for a let-through energy of 825 A²s for a period of 30 seconds.

Information:

Exceeding the maximum let-through energy can result in damage to the module.

- If maximum current I_{boost} is drawn for maximum time t_{boost} , the continuous current of 5 A can be drawn for the remaining time of 30 seconds.
- If maximum current I_{boost} is drawn for more than maximum time t_{boost} , the current is not permitted to exceed the calculated residual current for the remaining time of 30 seconds (see example below).
- At the end of a 30 second period with increased current consumption, 5 A continuous current or a higher current can be drawn again.

Calculating the residual current

$$I_{\text{boost}}^2 \cdot t_{\text{boost}} + I_{\text{residual}}^2 \cdot (30 - t_{\text{boost}}) \leq 825 \text{ A}^2 \text{ s}$$

$$I_{\text{residual}} = \sqrt{\frac{825 \text{ A}^2 \text{ s} - I_{\text{boost}}^2 \cdot t_{\text{boost}}}{30 \text{ s} - t_{\text{boost}}}}$$

Example

A boost current of 8 A is needed for a duration of 3 seconds. According to the formula, the residual current of 4.84 A is not permitted to be exceeded for the remaining 27 seconds.

$$I_{\text{residual}} = \sqrt{\frac{825 \text{ A}^2 \text{ s} - 8 \text{ A}^2 \cdot 3 \text{ s}}{30 \text{ s} - 3 \text{ s}}} = 4.84 \text{ A}$$

I_{boost} values if I²T = 825 A²s and $I_{\text{residual}} = 5 \text{ A}$

| t_{boost} s | I_{boost} A | t_{residual} s | t_{boost} s | I_{boost} A | t_{residual} s |
|-------------------------|-------------------------|----------------------------|-------------------------|-------------------------|----------------------------|
| 1 | 10.00 | 29 | 16 | 5.45 | 14 |
| 2 | 7.91 | 28 | 17 | 5.42 | 13 |
| 3 | 7.07 | 27 | 18 | 5.40 | 12 |
| 4 | 6.61 | 26 | 19 | 5.38 | 11 |
| 5 | 6.32 | 25 | 20 | 5.36 | 10 |
| 6 | 6.12 | 25 | 21 | 5.35 | 9 |
| 7 | 5.98 | 23 | 22 | 5.33 | 8 |
| 9 | 5.77 | 21 | 23 | 5.32 | 7 |
| 10 | 5.70 | 20 | 24 | 5.30 | 6 |
| 11 | 5.64 | 19 | 25 | 5.29 | 5 |
| 12 | 5.59 | 18 | 26 | 5.28 | 4 |
| 13 | 5.55 | 17 | 27 | 5.27 | 3 |
| 14 | 5.51 | 16 | 28 | 5.26 | 2 |
| 15 | 5.48 | 15 | 29 | 5.25 | 1 |
| | | | 30 | 5.24 | 0 |

These values correspond to the following curve for let-through current I_{2T}:

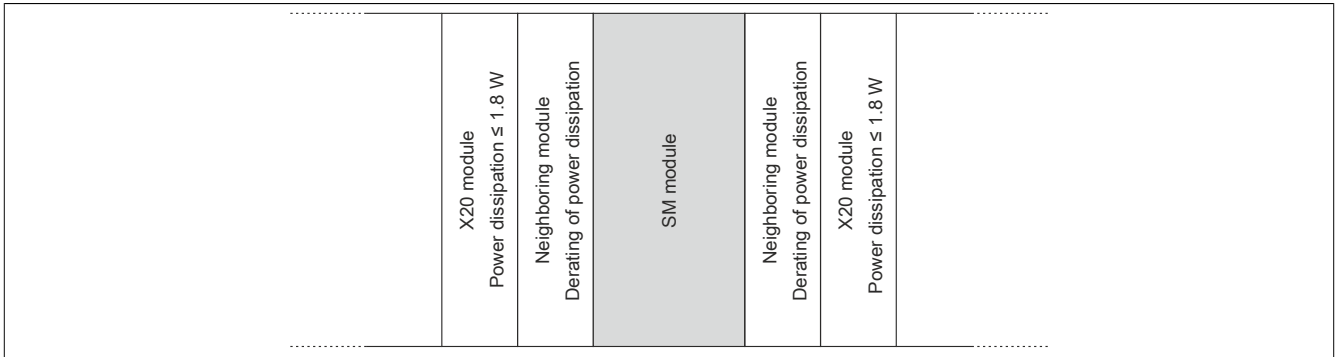

9.25.10.15 Derating

Only modules with a maximum power dissipation of 1 W are permitted to be operated next to the SM module. To ensure proper operation, observe the derating values listed below:

For an example of calculating the power dissipation of I/O modules, see section "[Power dissipation calculation of I/O modules](#)" on page 101.

Power dissipation derating for neighboring modules

The power dissipation of immediate neighboring modules of the SM module is permitted to be 1 W. If the SM module is operated at the rated load over the entire temperature range (5 A nominal current), the power dissipation of neighboring modules must be derated starting at 45°C.

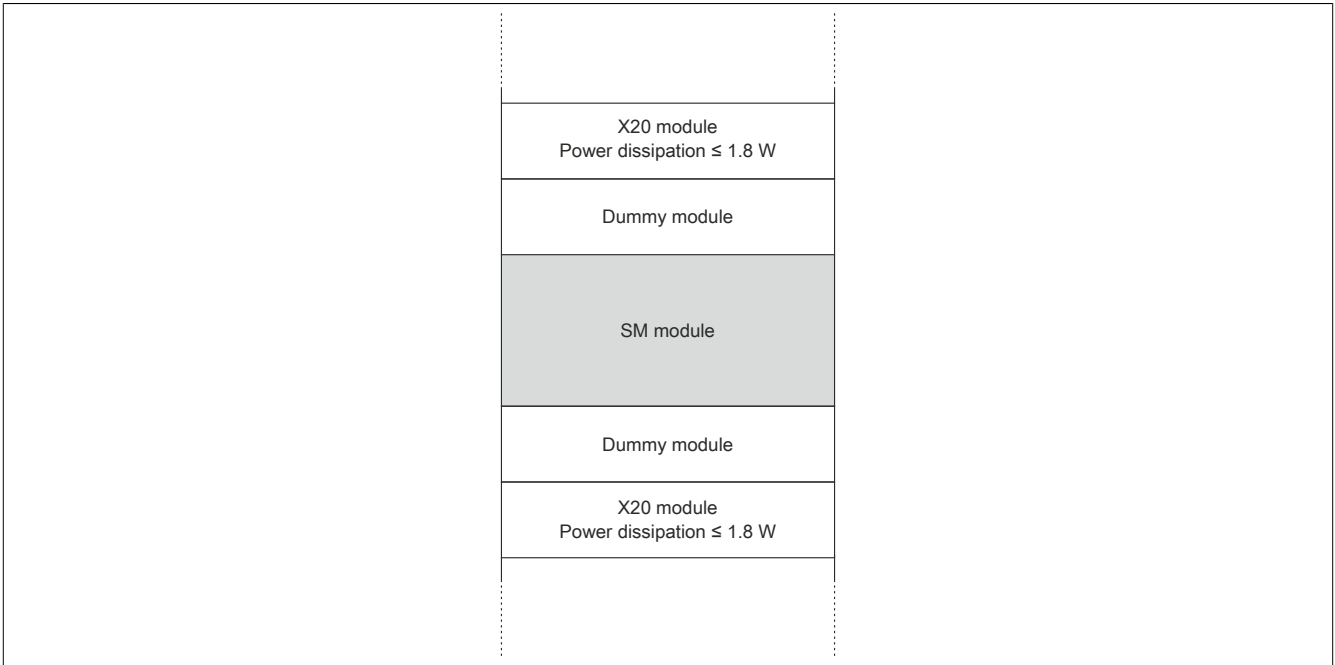

Current derating of the SM module

If the power dissipation of the neighboring modules to the SM module is 1 W, then the current of the SM module must be derated starting at 45°C.

Derating for vertical mounting orientation

When operating the module in a vertical mounting orientation, dummy modules must be connected as neighboring modules. There is no derating in this configuration.

9.25.10.16 Register description

9.25.10.16.1 mapp Motion system requirements

This module can be operated with mapp Motion function blocks. The following minimum versions are required for this:

- Upgrade version 2.2.0.0
- Automation Studio 4.7.2
- Automation Runtime 4.72

9.25.10.16.2 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.25.10.16.3 Function model 0 - "Standard" without SDC

| Register | Name | Data type | Read | | Write | |

1) The offset specifies the position of the register within the CAN object.

9.25.10.16.5.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see "Using I/O modules on the bus controller" on page 3789.

9.25.10.16.5.2 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN I/O.

9.25.10.16.6 Register description: General registers

9.25.10.16.6.1 General configuration registers

Determining the SGT parameters

Due to the dependence of the [MotorLoad value](#) on motor-specific properties and application-specific load and speed requirements, the operating conditions should be matched to the actual application.

To reliably detect a standstill of the motor, the stall threshold must be determined. The stall threshold should be a value within the operating limits and slightly higher than the minimum value before an actual motor standstill occurs.

- Parameter [SGT_Value01x](#) is used to compensate for an offset that results from the back EMF of the motor. For this purpose, the maximum load that the motor can run without blocking must be determined. Ideally, the MotorLoad load value should drop to 0 before a step loss due to overload causes the motor to stop. If the value of [SGT_Value01x](#) is set so that a value of 0 is displayed at maximum motor load, then the stall is precisely detected and the [stall error bit](#) is set correctly. For some motors, however, stall detection is very difficult to use or cannot be used at all. With these motors, no settings can be determined where the motor stops without slipping, e.g. due to electrical parameters or too little magnetic field feedback from the motor.
- [SGT_Speed01x](#) sets the threshold value at which speed the determined [SGT_Speed01x](#) becomes active. These are:

| | |
|---------------------|--|
| SGT_Value01a | From 0 to SGT_Speed01a |
| SGT_Value01b | From SGT_Speed01b to maximum |

Since the [MotorLoad value](#) drops to 0 during acceleration from standstill, this would be incorrectly detected as a stall and the motor would stop again immediately. Register [StallDetectMinSpeed01](#) can therefore be used to set a minimum speed at which stall detection is enabled.

Information:

- **At very low motor speeds (<1 revolution/second), stall detection cannot be carried out reliably due to low back EMF values.**
- **At very high motor speeds, at which the sinusoidal motor current can no longer be impressed into the motor coil, poor responsiveness can also occur.**

Determining the motor load characteristic curve

To be able to set the points (SGT_Value01a and SGT_Value01b) for the offset of the MotorLoad value, creating a motor load characteristic curve is helpful.

This graph shows an example of 200 steps per revolution:

| | SGT_Value | SGT_Speed |
|-----------|-----------|--|
| Value (a) | 4 | 129 revolutions/minute = 430 steps/second |
| Value (b) | 12 | 392 revolutions/minute = 1307 steps/second |

Legend

| | |
|------------|--|
| Green line | Motor load characteristic curve without load |
| Red line | Offset-corrected motor load characteristic curve |
| Black line | Interpolated motor load characteristic curve |
| * | Minimum speed for stall detection (>10 rpm) |
| ** | Back EMF reaches supply voltage |

Since the back EMF increases with increasing speed (MotorLoad value decreases to 0) and counteracts, there is a maximum speed for stall detection.

SGT speed

Name:

SGT_Speed01a to SGT_Speed01b

The associated speed value for the respective SGT_Value can be set in these registers.

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | In microsteps / X2X cycle (function model "Standard") In microsteps/cycle (function models "Bus controller" and "Ramp") |

SGT correction values

Name:

SGT_Value01a to SGT_Value01b

These registers optimize the motor load measurement.

The SGT value (Stallguard threshold) optimizes the motor load measurement. A negative value increases the sensitivity of the measurement; a positive value decreases it.

The correction value used depends on the value of SGT_Speed. The following applies:

- SGT_Value01 is used if the motor speed \leq SGTSpeed01.
- SGT_Value02 is used if the motor speed \geq SGTSpeed02.
- If the motor speed lies between the values, the SGT_Value is interpolated linearly.

The initial value for the optimization is 0. Values below -10 or over +10 should not be used.

| Data type | Values |
|-----------|-----------|
| INT | -64 to 63 |

Load-dependent current control

Load-dependent current control uses the **MotorLoad** value to reduce the current for the motor when the motor is only slightly loaded. In addition to saving energy, this also reduces the noise level of the motor. In addition, the motor is not heated as much. If a heavier load is again placed on the motor, the motor current is increased and thus more torque can be applied.

To set the load-dependent current control, 2 parameters must be set with "**MotorLoad_UpperLimit**" on page 2767 and "**MotorLoad_LowerLimit**" on page 2767 so that they can be increased or decreased as needed.

Stall detection for constant speed

If stall detection is only needed for a constant speed, the module can be configured as follows:

- 1) Set the initial values.
 - Disable current control. (**CurrentControlEnabel01** = 0)
 - Disable stall detection. (**StallDetectMinSpeed01** = 65535)
 - Set register **SGT_Speed01x** to 0.
 - Set register **SGT_Value01x** to 0.
- 2) Operate the motor at the speed needed for the application without load and observe the **MotorLoad** value.
- 3) Adjust the value.
 - a) Slowly increase the load on the motor. If the motor stops before the **MotorLoad** value indicates 0, reduce **SGT_Value01x** by 1.

Information:

Registers **SGT_Value01a and **SGT_Value01b** must always be set to the same value!**

- b) If the **MotorLoad** value is 0 before the motor stops, increase **SGT_Value01x** by 1. The optimal setting is achieved when the **MotorLoad** value remains above 0 at the maximum load necessary. If the value becomes 0, the maximum load on the motor is exceeded. In this case, bit 0 "StallError" is set in register **Error status**.
- 4) In register **StallDetectMinSpeed01**, set the speed value from which stall detection is enabled.

Stall detection for variable speeds

If stall detection is needed for a range of speeds (SGT_Speed01a and SGT_Speed01b), the module can be configured as follows:

- 1) Set the initial values.
 - Disable current control. (CurrentControlEnabel01 = 0)
 - Disable stall detection. (StallDetectMinSpeed01 = 65535)
 - Set register SGT_Speed01x to 0.
 - Set register SGT_Value01x to 0.
- 2) Operate the motor at the start of the speed range (SGT_Speed01a) without load and observe the MotorLoad value.
- 3) Adjust the value.
 - a) Slowly increase the load on the motor. If the motor stops before the MotorLoad value indicates 0, reduce SGT_Value01x by 1.
 - b) If the MotorLoad value is 0 before the motor stops, increase SGT_Value01x by 1. The optimal setting is achieved when the MotorLoad value remains above 0 at the maximum load necessary. If the value becomes 0, the maximum load on the motor is exceeded. In this case, bit 0 "StallError" is set in register Error status.
- 4) Operate the motor at the end of the speed range (SGT_Speed01b) without load and observe the MotorLoad value.
- 5) Adjust the value, see 3.
- 6) Set the determined range values.

The SGT_Value0x values between the range start and range end are interpolated linearly.

 - Set SGT_Value01a and SGT_Speed01a for the range start with the determined values.
 - Set SGT_Value01b and SGT_Speed01b for the range end with the determined values.
- 7) In register StallDetectMinSpeed01, set the speed value from which stall detection is enabled.

Configuring current control

Name:

CfO_SmartEnable01

The values for load-dependent current control can be set in this register. For reduced motor loads, the power supply can be reduced to a minimum of 25% nominal current in order to save electricity.

For increased motor loads, the module automatically adjusts the power supply according to the set values.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|--------------------------------|---------|--|
| 0 - 3 | MotorLoad_LowerLimit | 0 | Current control disabled (bus controller default setting) |
| | | 1 to 15 | |
| 4 | Reserved | - | |
| 5 - 6 | Current increase ¹⁾ | 0 | 1 measured values (bus controller default setting) |
| | | 1 | 2 measured values |
| | | 2 | 4 measured values |
| | | 3 | 8 measured value |
| 7 | Reserved | - | |
| 8 - 11 | MotorLoad_UpperLimit | 0 to 15 | |
| 12 | Reserved | - | |
| 13 - 14 | Current decrease ¹⁾ | 0 | 32 measured values (bus controller default setting) |
| | | 1 | 8 measured values |
| | | 2 | 2 measured values |
| | | 3 | 1 measured value |
| 15 | Current reduction | 0 | Reduction to 50% of the nominal current (bus controller default setting) |
| | | 1 | Reduction to 25% of the nominal current |

1) The measured values are recorded with each full step of the motor.

MotorLoad_LowerLimit

Increase of the current up to a maximum of 100% of the nominal current set in register "ConfigOutput04" on page 2769 if `MotorLoad` < (`MotorLoad_LowerLimit` * 32). If `MotorLoad_LowerLimit` = 0, load-dependent current control is disabled.

Current increase

Specifies the number `MotorLoad` measured values that are less than or equal to the limit value (`MotorLoad_LowerLimit` * 32) in order to increase current.

MotorLoad_UpperLimit

Reduction of the current if `MotorLoad` > (`MotorLoad_LowerLimit` + `MotorLoad_UpperLimit` + 1) * 32.

Current decrease

Number of `MotorLoad` measured values that are greater than or equal to the limit value (`MotorLoad_LowerLimit` + `MotorLoad_UpperLimit` + 1) * 32 in order to decrease the current.

Current reduction

Maximum reduction of the current to 25% or 50% of the nominal current.

9.25.10.16.7 Register description: Function model "Standard", general registers**9.25.10.16.7.1 Configuration registers****Minimum speed for stall detection**

Name:

StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled. This means that stall detection principally does not work at low speeds.

| Data type | Values | Information |
|-----------|-------------|------------------------------------|
| UINT | 0 to 65,535 | Minimum speed in steps per second. |

Full step threshold

Name:

FullStepThreshold01

This register configures a rotational speed. When this defined speed has been reached, the drive will automatically change from microsteps to full step mode. This makes it possible to optimize the torque at higher speeds, while microstep mode ensures optimal radial runout at lower speeds.

It does not make sense to change to full step mode at a standstill because fine positioning would then no longer be possible. This is why value "0" does not make sense in the full step threshold register and is interpreted as disabling full step mode (i.e. the motor will always be operated in microstep mode).

| Data type | Values | Information |
|-----------|-------------|-------------------------|
| UINT | 0 | Full step mode disabled |
| | 1 to 65,535 | Steps/second |

Example

Microstep mode should change to full step mode at 500 steps/second. On a motor with 200 steps per revolution, this would be equal to a speed of:

$$T^{-1} = \frac{500 \text{ steps/second}}{200 \text{ steps/revolution}} = 2.5 \frac{\text{revolutions}}{\text{second}} = 150 \text{ min}^{-1}$$

Holding current, nominal current and maximum current

Name:

ConfigOutput03 (holding current)

ConfigOutput04 (nominal current)

ConfigOutput05 (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

Information:

The maximum current must always be configured higher than the nominal current.

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

| Register | Description |
|-----------------|---|
| Nominal current | Current during normal operation |
| Maximum current | Should be selected if a higher motor torque is required briefly during acceleration phases. |
| Holding current | The holding current should be used in situations when less torque is required (e.g. at a standstill). This reduces the amount of heat generated by the motor. |

Switching between preset current values (holding current, rated current, maximum current):

| Function model | Switching between preset current values at runtime |
|---------------------------------------|--|
| Standard | Using bits 14 and 15 in registers "Motor StepX" on page 2774 |
| Standard with enabled SDC information | Using register "Motor current" on page 2779 |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 200 | Percent of the module's rated current <ul style="list-style-type: none"> • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 200% corresponds to the maximum current of the motor bridge power unit listed in the technical data. |

Counter configuration

Name:

ConfigOutput09

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------------|-------|--|
| 0 | ABR latch function | 0 | Negative edge: Disable ABR latch function |
| | | 1 | Positive edge: Enable ABR latch function. After a latch event has occurred, the latch function can be started again on a new rising edge. |
| 1 - 2 | Definition of the latch mode | 00 | ABR latch counter state unconditionally |
| | | 01 | ABR latch counter state on a positive edge of input R |
| | | 10 | ABR latch counter state on a negative edge of input R |
| | | 11 | Reserved |
| 3 | | 0 | <ul style="list-style-type: none"> • Position sync: Internal position counter • Position async: ABR counter state • Position latched sync: Internal position counter • Position latched async: ABR counter state |
| | | 1 | <ul style="list-style-type: none"> • Position sync: ABR counter state • Position async: Internal position counter • Position latched sync: ABR counter state • Position latched async: Internal position counter |
| 4 - 7 | Reserved | | |

1) These registers are not available in function model "Standard" with SDC information enabled.

Motor ID trigger

Name:

MotorIdentTrigger

With this register, a measurement of the motor ID can be initiated acyclically (see "[Motor identification](#)" on page 2772). The application must ensure that the conditions for measurement are met (see table "Notes" in register "[Motor identification](#)" on page 2772).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|---|
| 0 | | 0 | No effect |
| | | 1 | Positive edge triggers motor identifier measurement |
| 1 - 7 | Reserved | 0 | |

9.25.10.16.7.2 Registers for reading back the configuration

Reading back the holding current, nominal current and maximum current

ConfigOutput03Read (holding current)

ConfigOutput04Read (nominal current)

ConfigOutput05Read (maximum current)

These registers are used to read the respective current values in percent.

| Register | Description |
|-----------------|--|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases |
| Holding current | Current when motor is at standstill |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 255 | Percentage of module's nominal current (100% corresponds to the nominal current of the motor bridge power unit in the technical data) |

9.25.10.16.7.3 Communication registers

Measuring motor load

Name:

MotorLoad

This register contains the current measured load value for stall detection. A high value indicates a small load on the motor; the lower the value, the higher the motor load. The SGT values (see "[SGT speed](#)" on page 2765 and "[SGT correction values](#)" on page 2765) should be set so that the motor load returns value 0 at maximum load (shortly before stall).

This register can be shown and hidden via the module configuration.

| Data type | Values |
|-----------|-----------|
| UINT | 0 to 1023 |

Module configuration 1

Name:

ConfigOutput02

The number of transfer values and the resolution of microsteps for the drive can be configured in this register.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 | The setting for these two bits determines the meaning of bits 2 and 3 in register "Input counter value" on page 2776. | x | |
| 1 - 2 | Reserved | 0 | |

| 7 - 15 | Reserved | 0 | |

Position sync/async

Name:

PositionSync (function model 1 - "Standard" with SDC)

ActPos01 (function model 0 - "Standard" without SDC)

Positionasync

Depending on the [Counter configuration](#), these registers can be used to read either the internal position counter or the counter value on the ABR input.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

| Register | Counter configuration | |
|--------------------------|---------------------------|---------------------------|
| | Bit 3 = 0 | Bit 3 = 1 |
| Position sync (ActPos01) | Internal position counter | ABR counter |
| Position async | ABR counter | Internal position counter |

Internal position counter

The internal position counter is the position calculated by the SM module (position setpoint). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the "Module configuration 1" on page 2771). In function model "Standard" with SDC, this value is defined as "8-bit microstep" and cannot be changed.

Example of the internal position counter format (7-bit microsteps, i.e. set bit 5 and 6 of the module configuration to binary 10):

ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

Motor identification

Name:

Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. After successful measurement, this register contains the time [µs] required to apply a current increase of $\Delta I = 1 \text{ A}$ to a motor winding.

This depends on:

- Operating voltage
- Inductance and resistance of the motor winding

| Notes | | |
|-----------|---|--|
| 1) | To achieve reproducible results, the measurement must be made under the following defined conditions: | |
| | a) | Motor is at standstill. |
| | b) | The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: <ul style="list-style-type: none"> • Full steps are divisible by 4. • Microsteps = 0 |
| 2) | Condition 1b) is fulfilled after a the SM module is reset or switched on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application. | |
| 3) | The current range from approximately 1/3 of the nominal current up to the nominal current is used as operating range for determining the motor identifier. | |
| Data type | Motor ID values | Explanation |
| UINT | 0 | No motor identifier available (after switching on for as long as the measurement conditions are not met) |
| | 1 to 32767 | Valid range of values for the motor ID register (in µs) |
| | 65534 | Invalid value: Overflow |

Error status

Name: The names of the bits are different depending on whether [SDC information](#) is enabled or disabled.

Without SDC

StallError

Overtemperature

ErrorCurrentError

OvercurrentError

-

With SDC

StallError01

Overtemperature01

ErrorCurrentError01

OvercurrentError01

DrvOK01

OpenCircuit01 to OpenCircuit04

The current error status of the drive is indicated in this register. Each bit indicates a certain error or status. If an error is registered in bits 0 to 3, then the corresponding bit remains set until the error has been acknowledged (see "[Module configuration 2](#)" on page 2777 and "[Error acknowledgment](#)" on page 2780).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|---|
| 0 | StallError(01) | 0 | No stall |
| | | 1 | Stall |
| 1 | Overtemperature error OvertemperatureError(01) | 0 | No overtemperature |
| | | 1 | Overtemperature |
| 2 | Current error CurrentError(01) | 0 | No current error |
| | | 1 | Current error |
| 3 | Overcurrent error OvercurrentError(01) | 0 | No overcurrent |
| | | 1 | Overcurrent |
| 4 | Status of the drive DrvOk0 ¹⁾ | 0 | An error was triggered for the motor axis |
| | | 1 | The drive is running error-free |
| 5 - 11 | Reserved | 0 | |
| 12 | Open circuit OpenCircuit01 | 0 | No open circuit |
| | | 1 | Open circuit detected |
| ... | | ... | |
| 15 | Open circuit OpenCircuit04 | 0 | No open circuit |
| | | 1 | Open circuit detected |

1) Only when SDC information is enabled

Overtemperature error

The "Overtemperature" error bit can be set for the following reasons:

- A specific temperature was exceeded near the channel due to overload
- The module temperature rises above the limit (see ["Shutdown in the event of overtemperature \(starting at 116°C\)" on page 2755](#)).

Current error

This error bit occurs whenever the required current cannot be supplied to the motor windings. This can be (but is not necessarily) caused by an open circuit. At higher speeds (depending on the motor), this error can also occur without an open circuit. In this case it is simply no longer possible to supply the desired current to the motor windings. Because of the Back-EMF on the motor, this bit is set at slightly lower speeds if the motor is operated with no load compared with full or partial loads.

Overcurrent error

Overcurrent occurs if there is not enough voltage for the motor winding (e.g. short circuit).

Status of the drive

The status of the drive is only shown when SDC information is enabled. The drive bit is 1 when the following conditions are met:

- Motor turned on (see ["Motor current" on page 2779](#))
- MotorID measurement is completed
- Motor is supplied with current
- Motor settling time has passed
- Supply voltage is in the valid range
- No overtemperature fault
- Preset position value is valid (see ["SDC life sign monitoring" on page 2779](#))

Open circuit

The module is equipped with open circuit detection for the digital inputs. If the digital input is not connected to ground or to 24 V, an open circuit is detected.

9.25.10.16.8 Register description: Function model "Standard" without SDC information

9.25.10.16.8.1 Communication registers

Motor StepX

Name:

MotorStep0 to MotorStep3

These registers specify the number and direction of steps that must be moved by the module during the next X2X cycle and also select the motor current (see also "[Holding current, nominal current and maximum current](#)" on page 2769).

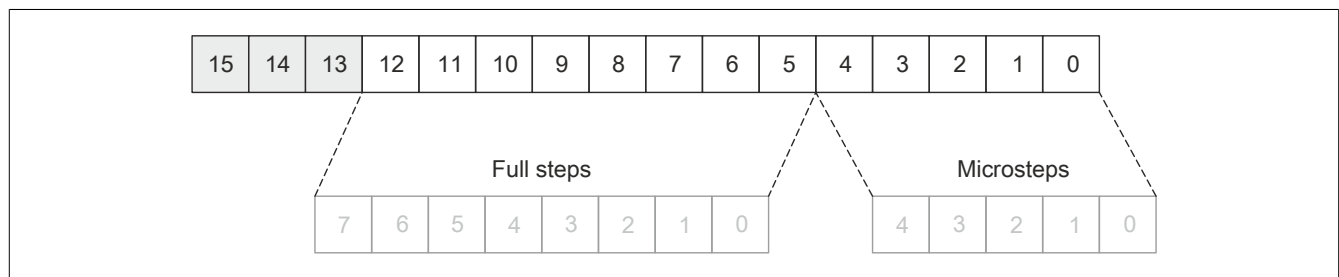

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|-------|-------------------|
| 0 - 12 | Number of steps for the module to move during the next X2X cycle | x | |
| 13 | Direction of movement | 0 | Positive |
| | | 1 | Negative |
| 14 - 15 | Selection of motor current | 00 | Motor not powered |
| | | 01 | Holding current |
| | | 10 | Nominal current |
| | | 11 | Maximum current |

Depending on the necessary resolution and maximum configurable speed, module configuration 1 can be used to specify which bit position is used as the 1s position for full steps (see bits 5 and 6 of "[Module configuration 1](#)" on page 2771).

Example for 5-bit microsteps (set bits 5 and 6 of the module configuration to binary 00):

The number of transfer values per X2X cycle is specified by bits 3 and 4 in the module configuration 1 (see "[Module configuration 1](#)" on page 2771). If only one transfer value (bits 3 and 4 = 00) is specified, then the motor is advanced by MotorStep0 until the next X2X cycle. If 2 or 4 transfer values are specified, they are added and executed in the next X2X cycle.

Position latched sync-async

Name:

PositionLatchedSync

PositionLatchedASync

The position counter (internal position counter or ABR counter) is applied at the latch event (see "Module configuration 2" on page 2777). Bits 3 and 7 of register "Counter configuration" on page 2769 are used to determine which counter state (internal position counter or ABR encoder) should be saved in registers "Position latched sync" and "Position latched async".

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

| Register | Counter configuration | |
|----------------|---------------------------|---------------------------|
| | Bit 3 = 0 | Bit 3 = 1 |
| Position sync | Internal position counter | ABR counter |
| Position async | ABR counter | Internal position counter |

Internal position counter

The internal position counter is the position calculated by the module (position setpoint). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the "Module configuration 1" on page 2771).

Example of the internal position counter format (7-bit microsteps, i.e. set bit 5 and 6 of the module configuration to binary 10):

ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

usSinceTrigger

Name:

usSinceTrigger

This register indicates the time in μs that has passed since the trigger event occurred (see "Module configuration 2" on page 2777).

Information:

The absolute accuracy of the trigger can be delayed up to 5 μs due to the input filter of the digital inputs.

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Stepper latch trigger status

Name:
 LatchInput
 LatchDone
 TriggerInput

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|---|
| 0 | Latch input: | x | Digital input for the latch event (level) |
| 1 | LatchDone | x | Changes its state each time the counter state is successfully latched (reset value = 0) |
| 2 - 3 | Reserved | - | |
| 4 | TriggerInput | x | Trigger input (level) |
| 5 - 7 | Reserved | 0 | |

9.25.10.16.8.2 Input counter value

Name:
 ModulePowerSupplyError
 StatusInput01 to StatusInput04

This register indicates the state of the digital inputs and counters.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|---|--|
| 0 | ModulePowerSupplyError | 0 | OK |
| | | 1 | Module power supply error |
| 1 | Reserved | 0 | |
| 2 | StatusInput01 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 1 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | x | Ref toggle bit for counter 1: The state of this bit is changed after homing is completed. |
| 3 | StatusInput02 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 2 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | 0 | The homing procedure for the ABR counter is active. |
| | | 1 | The homing procedure of the ABR counter is completed. |
| 4 | StatusInput03 | 0 or 1 | Input state - Digital input 3 |
| 5 | StatusInput04 | 0 or 1 | Input state - Digital input 4 |
| 6 - 7 | Reserved | 0 | |

9.25.10.16.8.3 Configuration registers

Module configuration 2

Name:

StartLatch

TriggerEdgePos

TriggerEdgeNeg

StartTrigger

TriggerEdge

ClearError

CurrentControlEnable

The trigger functions for the stepper motor can be configured with this register.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|---|
| 0 | Latch function for stepper motor 2 Latch byte | 0 | The latch function for stepper motor position is disabled on the negative edge of this bit. |
| | | 1 | The latch function for stepper motor position is disabled on the positive edge of this bit. |
| 1 - 2 | Latch mode for stepper motor TriggerEdgePos (bit 1) TriggerEdgeNeg (bit 2) | 00 | Latch position of stepper motor unconditional |
| | | 01 | Latch position of stepper motor on positive edge of input DI 3 |
| | | 10 | Latch position of stepper motor on negative edge of input DI 3 |
| | | 11 | Reserved |
| 3 | TriggerEdge | 0 | Trigger edge (input DI 4) = Positive |
| | | 1 | Trigger edge (input DI 4) = Negative |
| 4 | Enable trigger (on change) StartTrigger | x | |
| 5 | ClearError | 0 | No effect |
| | | 1 | Error acknowledgment for motor (for more information, see "Error status" on page 2772) |
| 6 | Reserved | - | |
| 7 | CurrentControlEnable | 0 | Enable load-dependent current control |
| | | 1 | Disable load-dependent current control |

Trigger function procedure:

- Selection of the desired trigger edge using bit 3
- Enabling of the trigger function by changing the state of bit 4. Changing this bit deletes `usSinceTrigger` (μ s counter).
- When the trigger event occurs, μ s counter `usSinceTrigger` is started.
- Counter `usSinceTrigger` cannot overflow, i.e. the counter is stopped at $2^{16} - 1$ and retains this value until the next time the trigger function is enabled.

The trigger function can be re-enabled at any time by changing the state of bit 4, regardless of whether a trigger event has occurred or if `usSinceTrigger` has reached the maximum value.

Position sync 2

Name:

PositionSync02

This register contains the state of either the position counter or the ABR counter depending on [Counter configuration](#) (bit 3). It behaves exactly complementary to register "[Position sync](#)" on page 2771.

If "Position sync" contains the position counter, then register "PositionSync02" contains the ABR counter state, and vice versa.

By default, the register is not visible in the I/O map; it must first be enabled in the I/O configuration.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.10.16.9 Register description: Function model "Standard" with SDC information

9.25.10.16.9.1 Configuration registers

SDC configuration

Name:
SDCConfig01

This register can be used to enable/disable additional SDC information.

The additional cyclic registers are hidden or shown depending on whether SDC information is disabled or enabled. Compare the two variants of function model "Standard" [with](#) and [without enabled SDC information](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------------------------|-------|----------------------|
| 0 | Trigger edge | 0 | Rising trigger edge |
| | | 1 | Falling trigger edge |
| 1 - 5 | Reserved | 0 | |
| 6 | SDC life sign monitoring | 0 | Disabled |
| | | 1 | Enabled |
| 7 | SDC information ¹⁾ | 0 | Disabled |
| | | 1 | Enabled |

- 1) When the "SDC information" bit is enabled, the "EncOK01" bit is shown in the Automation Studio I/O mapping. This bit is linked to the ModulOK bit and always indicates its value.

Information:

Neither SDC information nor SDC life sign monitoring is permitted to be changed at runtime.

Module configuration 1 with SDC

Register "Module configuration 1" on page 2771 is ignored in function model "Standard" with SDC information enabled. The module behaves as follows, i.e. whether the module configuration was written in this way:

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 | Meaning of bits 2 and 3 in register "Input counter value" on page 2780 | | |
| 1 - 2 | Reserved | 0 | |
| 3 - 4 | Number of transfer values per X2X cycle | 00 | 1x Δs / Δt (transfer values: motor settings Motor1Step0) |
| 5 - 6 | Resolution of microsteps | 11 | 8-bit microsteps |
| 7 - 15 | Reserved | 0 | |

Motor settling time

Name:
MotorSettlingTime01

This register determines the motor setting time. The motor settling time determines the minimum time between when the motor is powered on to when the DrvOk bit is set (see "Error status" on page 2772). The setting is made in steps of 10 ms.

| Data type | Values | Information |
|-----------|----------|---------------------------------|
| USINT | 1 to 255 | 10 ms to 2.55 s, default: 10 ms |

Switch-off delay

Name:
DelayedCurrentSwitchOff01

If the [SDC life sign monitoring](#) is triggered (i.e. the [NetTime timestamp](#) is in the past) the motor is decelerated at nominal current with speed setpoint = 0.

Then the motor is switched off after the delay configured with this register.

| Data type | Values | Information |
|-----------|----------|--|
| USINT | 0 to 255 | 0 to 25.5 s in steps of 100 ms (default: 100 ms) |

9.25.10.16.9.2 Communication registers

SDC life sign monitoring

Name:

SetTime01

The module uses SDC life sign monitoring to check whether valid values have been received for the speed setpoint.

SDC life sign monitoring is enabled in register "SDC configuration" on page 2778 by setting bit 6 (SDCSetTime = On).

If the specified [NetTime timestamp](#) is in the past, then an error is triggered for the motor axis (only when the motor is switched on). The module performs the following steps:

- 1) The CPU is informed of the error using the Drive bit (DrvOk) = 0
- 2) Braking at configured nominal current with speed setpoint = 0
- 3) Wait for configured turn-off delay to expire
- 4) Power off motor

When the timestamp is back within the valid range, the motor can be operated again by a rising edge on bit "DriveEnable" (see "[Motor current](#)" on page 2779) .

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Motor current

Name:

DriveEnable01

BoostCurrent01

StandstillCurrent01

CurrentControlEnable01

Bits 0 to 2 of this register control the motor's current feed.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|-------|---|
| 0 | DriveEnable01 | x | Motor powered |
| 1 | BoostCurrent01 | x | Maximum current |
| 2 | StandstillCurrent01 | x | Holding current |
| 3 - 6 | Reserved | 0 | |
| 7 | CurrentControlEnable01 | 0 | Load-dependent current control disabled |
| | | 1 | Load-dependent current control enabled |

The possible status of bits 0 to 2

| StandstillCurrent01 | BoostCurrent01 | DriveEnable01 | Description |
|---------------------|----------------|---------------|-----------------------------------|
| x | x | 0 | Motor not supplied with current |
| 0 | 0 | 1 | Rated current supplied to motor |
| 0 | 1 | 1 | Maximum current supplied to motor |
| 1 | 0 | 1 | Holding current supplied to motor |
| 1 | 1 | 1 | Holding current supplied to motor |

Lifecycle counter

Name:

LifeCnt

This register is incremented by one with each X2X Link cycle.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Input counter value

Name:

ModulePowerSupplyError

StatusInput01 to StatusInput04

This register indicates the state of the digital inputs and counters.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|---|--|
| 0 | ModulePowerSupplyError | 0 | OK |
| | | 1 | Module power supply error |
| 1 | Reserved | 0 | |
| 2 | StatusInput01 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 1 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | x | Ref toggle bit for counter 1: The state of this bit is changed after homing is completed. |
| 3 | StatusInput02 | If bit 0 in Module configuration 1 = 0 | |
| | | 0 or 1 | Input state - Digital input 2 |
| | | If bit 0 in Module configuration 1 = 1 | |
| | | 0 | The homing procedure for the ABR counter is active. |
| | | 1 | The homing procedure of the ABR counter is completed. |
| 4 | StatusInput03 | 0 or 1 | Input state - Digital input 3 |
| 5 | StatusInput04 | 0 or 1 | Input state - Digital input 4 |
| 6 - 7 | Reserved | 0 | |

Error acknowledgment

Name:

ClearError01

This register can be used to acknowledge errors that have occurred on the motor.

For more info, see ["Error status" on page 2772](#).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|--------------------------------|
| 0 - 4 | Reserved | 0 | |
| 5 | ClearError01 | 0 | No effect |
| | | 1 | Error acknowledgment for motor |
| 6 - 7 | Reserved | 0 | |

Motor1Step0

Name:

Motor1Step0

This registers is used to specify the number and direction of steps that should be carried out by the module during the next X2X cycle.

The value is specified with a resolution of 1/256 of a full step (corresponds to 8-bit microsteps).

The direction of movement is derived from the value's sign:

| Data type | Values | Information |
|-----------|--------|--|
| INT | >0 | Movement in the positive direction in 1/256 full steps |
| | <0 | Movement in the negative direction in 1/256 full steps |

Unlike function model "Standard" without enabled SDC information, the motor current is selected using a separate register (see register ["Motor current" on page 2779](#)).

Home position

Name:

RefPulsePos01

These 2 registers have the following contents:

| Register | Description |
|--|--|
| Home position of the internal position counter | This register contains the home position of the internal position counter. |
| Home position for the ABR counter | This register contains the home position of the ABR counter. |

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Setting "Position sync" in the Automation Studio I/O configuration can be used to select which of the 2 registers is addressed by variable RefPulsePos01.

| Variables in Automation Studio | I/O configuration, counter 01, option "Position sync" | |
|--|---|---|
| | Stepper counter 01 is indicated on ActPos01 . | ABR counter 01 is indicated on ActPos01 . |
| RefPulsePos01 | Home position of the internal position counter | Home position of the ABR counter |
| Option "Position sync" for counter 1 also sets bit 3 in register " Counter configuration " on page 2769: | | |
| Bit 3 (counter 1) | 0 | 1 |

Reference pulse counter

Name:

RefPulseCnt01

These 2 registers have the following contents:

| Register | Description |
|---|---|
| Reference pulse counter for the internal position counter | The reference pulses of the internal position counter are counted in this register. |
| Reference pulse counter for the ABR counter | The reference pulses of the ABR counter are counted in this register. |

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Setting "Position sync" in the Automation Studio I/O configuration can be used to select which of 2 registers is addressed by variable RefPulsePos01.

| Variables in Automation Studio | I/O configuration, counter 01, option "Position sync" | |
|--|---|---|
| | Stepper counter 01 is indicated on ActPos01 . | ABR counter 01 is indicated on ActPos01 . |
| RefPulseCnt01 | Reference pulse counter for the internal position counter | Reference pulse counter of the ABR counter |
| Option "Position sync" for counter 1 also sets bit 3 in register " Counter configuration " on page 2769: | | |
| Bit 3 (counter 1) | 0 | 1 |

NetTime of the position value

Name:

ActTime01

This register contains the NetTime of the most recent valid position value.

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on page 3035.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

Trigger counter

Name:

TriggerCnt01

This register contains a cyclic counter that is incremented with each trigger event.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Trigger timestamp

Name:

TriggerTime01

This register contains the NetTime instant of the most recent trigger event. The trigger edge must be configured in register "[SDC configuration](#)" on [page 2778](#).

For more information about NetTime and timestamps, see "[NetTime Technology](#)" on [page 3035](#).

Information:

The absolute accuracy of the trigger can be delayed up to 5 µs due to the input filter of the digital inputs.

| Data type | Values |
|-----------|-----------------|
| INT | -32768 to 32767 |

9.25.10.16.10 Register description: Function model 254 - "Bus controller" and function model 3 - "Ramp"

9.25.10.16.10.1 Configuration registers

Holding current, nominal current and maximum current

Name:

ConfigOutput03a (holding current)

ConfigOutput04a (nominal current)

ConfigOutput05a (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

| Register | Description |
|-----------------|---|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases. In the mode " Referencing during stall ", the rated current is always used instead of the maximum current, even in acceleration phases. |
| Holding current | Current when motor is at standstill |

When the current changes to a weaker value (e.g. when transitioning from the acceleration phase to the constant speed mode), the stronger current is maintained for an additional 100 ms. The following priority applies regardless of the values actually set: maximum current before nominal current before holding current.

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 200 | Percent of the module's rated current <ul style="list-style-type: none"> • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 200% corresponds to the maximum current of the motor bridge power unit listed in the technical data. Bus controller default setting: 0 |

Full step threshold

Name:

FullStepThreshold01

Starting with the speed specified in this register, the motor is operated in full step mode; it is operated in microstep mode below it.

| Data type | Values | Information |
|-----------|------------|---|
| UINT | 1 to 65534 | Speed in microsteps/cycle. Bus controller default setting: 0 |
| | 65535 | Motor is always operated in microstep mode |

Maximum speed

Name:

MaxSpeed01pos

This register defines the maximum speed for the absolute positioning modes (1, -123, -124, -125, -126).

Information:

The setting does not apply to the speed and homing modes (2, -127, -128).

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Speed in microsteps/cycle. Bus controller default setting: 0 |

Maximum acceleration

Name:

MaxAcc01

This register defines the maximum acceleration. (also applies for homing modes).

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Acceleration in microsteps/cycle ² . Bus controller default setting: 0 |

Maximum deceleration

Name:

MaxDec01

This register defines the maximum deceleration. (also applies for homing modes).

| Data type | Values | Information |
|-----------|-------------|--|
| UINT | 0 to 65,535 | Brake deceleration in microsteps/cycle ² . Bus controller default setting: 0 |

Reversing loop

Name:

RevLoop01

This parameter is only used in modes 1, -123, -124, -125, -126 (absolute positioning modes).

If the value for the reversing loop is not equal to 0, the target position is approached directly when coming from one direction; when coming from the other direction, the target position is initially overshoot by the configured number of steps before finally moving to the target position. This ensures that the target position is always approached from the same direction (to avoid mechanical backlash).

The sign of the defined value determines the direction in which the reversing loop runs.

| Sign | Effective direction |
|----------|--|
| Positive | Reversing loop in positive direction of movement |
| Negative | Reversing loop in negative direction of movement |

| Data type | Values | Information |
|-----------|-----------------|-----------------------------------|
| INT | -32768 to 32767 | Bus controller default setting: 0 |

Fixed position A

Name:

FixedPos01a

This register defines the position to move to in modes -124 (if the digital input is set to 1) and -125.

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Fixed position B

Name:
FixedPos01b

This register defines the position to move to in modes [-124](#) (if the digital input is set to 0) and [-126](#).

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Homing speed

Name:
RefSpeed01

This register sets the speed for homing modes [-127](#) and [-128](#).

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Speed in microsteps/cycle. Bus controller default setting: 0 |

Stall recognition delay

Name:
StallRecognitionDelay01

The value in this register is only relevant for [Referencing during stall](#).

A stall is only detected after the time specified here has expired and after the homing procedure has started.

For example, a setting of 4 (and a cycle time of 25 ms) means that a stall will not be detected until 100 ms after the motor starts moving (start of the homing procedure).

Set to 0 to eliminate delay.

| Data type | Values | Information |
|-----------|----------|---|
| USINT | 0 to 255 | In cycles, see " General configuration " on page 2785. Bus controller default setting: 0 |

Minimum speed for stall detection

Name:
StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled. No error is reported below this threshold value.

| Data type | Values | Information |
|-----------|-------------|---|
| UINT | 0 to 65,535 | Minimum speed in microsteps per cycle. Bus controller default setting: 0 |

Jerk time

Name:
JoltTime01

If a value other than 0 is assigned to this register, then jerk limitation is performed. This is done by averaging the values for the steps to be carried out (speed setpoint) in each cycle using a FIFO buffer. The jerk time corresponds to the number of FIFO elements (0 to 80). If a value greater than 80 is entered, then it will be limited internally to 80.

Changes made while a motor is running will be applied as soon as ...

- The motor has reached the set position (positioning mode only).
- The motor has stopped (all modes).

| Data type | Values | Information |
|-----------|---------|---|
| USINT | 0 | No jerk limitation time. Bus controller default setting: 0 |
| | 1 to 80 | Number of FIFO elements |

Homing configuration

Name:
RefConfig01

The homing mode can be set with this register.

| Data type | Values | Information |
|-----------|------------|--|
| SINT | -120 | Set home position |
| | -121 | Homing on positive edge of input DI 4 |
| | -122 | Homing on falling edge of input DI 4 |
| | -125 | Homing on positive edge of input DI 3 (R pulse). Bus controller default setting |
| | -126 | Homing on negative edge of input DI 3 (R pulse) |
| | -127 | Homing during stall detection |
| | -128 | Immediate homing |
| | All others | No effect |

General configuration

Name:
GeneralConfig01

Bit 0 of this register can be used to switch the positioning mode. This register can also be used to configure the cycle time of the motion profile generator.

- 0: "Mode 1: Position mode" without extended control word
- 1: "Mode 1: Position mode with extended control word"

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|--|
| 0 | Position mode | 0 | Without extended control word (bus controller default setting) |
| | | 1 | With extended control word |
| 1 - 2 | Cycle time of the motion profile generator ¹⁾ | 00 | 25 ms (bus controller default setting) |
| | | 01 | 10 ms |
| | | 10 | 5 ms |
| | | 11 | Reserved |
| 3 - 7 | Reserved | 0 | |

1) The cycle time for the motion profile generator is configured with this cycle. This cycle time affects the unit for specifying the speed and acceleration:

- Unit for speed: Microsteps/Cycle
- Unit for acceleration: Microsteps/Cycle²

Limit switch configuration

Name:

LimitSwitchConfig01

This register configures the behavior of the limit switches.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------|-------|---|
| 0 - 1 | Negative limit switch | 00 | Switched off (bus controller default setting) |
| | | 01 | Active if low |
| | | 10 | Reserved |
| | | 11 | Active if high |
| 2 - 3 | Positive limit switch | 00 | Switched off (bus controller default setting) |
| | | 01 | Active if low |
| | | 10 | Reserved |
| | | 11 | Active if high |
| 4 - 6 | Reserved | 0 | |
| 7 | Direction monitoring | 0 | Off (bus controller default setting) |
| | | 1 | On |

Negative/Positive limit switch:

When one of the limit switches is reached, a warning is triggered and the speed is decelerated to 0. There is no state change of "Device control state machine". This keeps current flowing to the motor.

The error that occurred can be read from the error code register. Normal operation can be resumed by acknowledging the warning. This will not restrict motor movement to a specific direction and the limit switch will not be triggered until the next active edge.

Overshooting the limit switch while braking

The limit switches are not linked with the corresponding direction of movement. If the limit switch is exceeded, another error will be triggered when reversing after acknowledging the initial error.

Direction monitoring

If this function is enabled, then the two limit switches will be linked with the respective direction of movement. This means that the negative limit switch is only triggered in the negative and the positive limit switch only in the positive direction of movement (specified direction).

This prevents specifying a movement in the wrong direction when direction monitoring is enabled and limit switches are active.

Warning!

If the motor is wired incorrectly with this configuration (wrong direction of movement), then the limit switch will not be triggered and the actual correct direction of movement will be denied. This will also be the case when the limit switch connections are reversed.

Software limit

Name:

PositionLimitMin01

PositionLimitMax01

This register configures software limits. The function is enabled if at least one of the two registers is not equal to zero.

These limits are effective in all positioning modes. Position overflow is not possible when this function is enabled. Movement is always contained within the two limits.

If a position is specified that violates the minimum/maximum software limit, the "Internal limit active" bit will be set in the "Status word" on page 2794 register. The motor movement will be stopped until a position is specified within the limits.

Bit "Internal limit active" will also be set in register "Status word" if incorrectly configured (minimum > maximum).

| Data type | Values | Information |
|-----------|------------------------------------|-----------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | Bus controller default setting: 0 |

Information:

The software limits will only be monitored when using the following CANopen bus controllers:

- X20BC0043-10
- X20BC0143-10
- X67BC4321-10
- X67BC4321.L08-10
- X67BC4321.L12-10

9.25.10.16.10.2 Reading back the configuration

Reading back the holding current, nominal current and maximum current

ConfigOutput03aRead (holding current)

ConfigOutput04aRead (nominal current)

ConfigOutput05aRead (maximum current)

These registers are used to read the respective current values in percent.

| Register | Description |
|-----------------|--|
| Nominal current | Current during operation at constant speed |
| Maximum current | Current during acceleration phases |
| Holding current | Current when motor is at standstill |

| Data type | Values | Unit |
|-----------|----------|---|
| USINT | 0 to 255 | Percentage of module's nominal current (100% corresponds to the nominal current of the motor bridge power unit in the technical data) |

9.25.10.16.10.3 Communication registers

Measuring motor load

Name:

MotorLoad

This register contains the current measured load value for stall detection. A high value indicates a small load on the motor; the lower the value, the higher the motor load. The SGT values (see "SGT speed" on page 2765 and "SGT correction values" on page 2765) should be set so that the motor load returns value 0 at maximum load (shortly before stall).

This register can be shown and hidden via the module configuration.

| Data type | Values |
|-----------|-----------|
| UINT | 0 to 1023 |

Set position/speed

Name:
AbsPos01

This register is used to set position or speed, depending on the operating mode.

- Position mode (see ["Mode" on page 2789](#)): Cyclic setting of the position setpoint in microsteps. In this mode, one micro-step is always 1/256 full-step.
- Speed mode (see ["Mode" on page 2789](#)): In this mode, this register is considered a signed speed setpoint.

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Control word

Name:
MpGenControl01

This register can be used to issue commands based on the module's state (see ["Operating function model "Ramp" on page 2797](#)).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|------------------------|-------|--|
| 0 | Switch on | x | |
| 1 | Enable voltage | x | |
| 2 | Quick stop | x | |
| 3 | Enable operation | x | |
| 4 - 6 | Mode-specific | x | |
| 7 | Fault reset | x | |
| 8 | Stop ¹⁾ | x | |
| 9 | CurrentControlEnable | 0 | Disable load-dependent current control |
| | | 1 | Enable load-dependent current control |
| 10 | Reserved | 0 | |
| 11 | Motor ID trigger | 0 | No effect |
| | | 1 | Rising edge: Motor ID trigger ²⁾ |
| 12 | Warning reset | 0 | No effect |
| | | 1 | Rising edge: Reset warnings |
| 13 | Undercurrent detection | 0 | Disable current error detection (default) |
| | | 1 | Enable current error detection |
| 14 | ABR counter sync/async | 0 | Default: <ul style="list-style-type: none"> • Internal position counter, cyclic • ABR counter, acyclic |
| | | 1 | <ul style="list-style-type: none"> • Internal position counter, acyclic • ABR counter, cyclic |
| 15 | Stall detection | 0 | Disable stall detection (default) |
| | | 1 | Enable stall detection |

1) The "Stop" bit is only evaluated when the extended control word is enabled (see ["General configuration" on page 2785](#)).

2) This bit can be used to trigger a measurement of the motor ID. Keep in mind that the application must ensure that the conditions for measurement are fulfilled (see table in the ["Motor identification" on page 2795](#) register).

Mode

Name:

MpGenMode01

| Data type | Values | Information |
|-----------|--------|---|
| SINT | 0 | No mode selected |
| | 1 | Depending on bit 0 in the "General configuration" on page 2785 register, the position mode will behave as follows: <ul style="list-style-type: none"> Position mode without extended control word: Move to target position as soon as the target position is changed Position mode with extended control word: Move to the target position as described in "Mode 1 - Position mode with extended control word" on page 2789 |
| | 2 | Speed mode: Constant speed |
| | -120 | Set home position |
| | -121 | Remaining distance mode |
| | -122 | Set actual position |
| | -123 | Move to target position when external input set |
| | -124 | Two-position module |
| | -125 | Move to fixed position A (position set acyclically) |
| | -126 | Move to fixed position B (position set acyclically) |
| | -127 | Positive homing (see also "Homing configuration" on page 2785) |
| | -128 | Negative homing (see also "Homing configuration" on page 2785) |

Information:

For all modes: The "Target reached" bit is set in the "Status word" on page 2794 register when the current action is finished (i.e. when the position or speed is reached, depending on the mode).

A new position or speed can be specified even before the current action is finished.

Mode 1 - Position mode

The position setpoint is specified in the "Set position/speed" on page 2788 register. The motor is then moved to this new position. This is done with a ramp function that accounts for the defined maximum speed and acceleration values.

The position setpoint can also be changed during an active positioning procedure.

The position setpoint is specified in microsteps (1/256 of a full step).

If bit 0 in the "General configuration" on page 2785 register is 0 (no extended control word), then the position setpoint will be applied as soon as it is different from the current position. Then the new position is used for the movement.

However, if bit 0 in the "General configuration" on page 2785 register is set to 1 (extended control word), then the position setpoint will be applied as described under "Mode 1 - Position mode with extended control word" on page 2789.

Mode 1 - Position mode with extended control word

Position mode with extended control word behaves like [Position mode 1](#) as described previously (without the extended control word), but the new position setpoint ("Position/Speed" on page 2788 register) is applied according to the [extended control word](#).

Extended control word

Commands can be issued using this register depending on the state of the module (see "Operating function model "Ramp"" on page 2797).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---|-------|---|
| 0 - 3 | Corresponds to the default Control word | x | |
| 4 | New setpoint | 0 | Do not apply target position. |
| | | 1 | Apply target position. |
| 5 | Change set immediately | 0 | Complete current positioning movement and then start next positioning movement |
| | | 1 | Interrupt current positioning movement and then start next positioning movement |
| 6 | abs / rel | 0 | Target position is an absolute value. |
| | | 1 | Target position is a relative value. |
| 7 | Corresponds to the default Control word | x | |
| 8 | Stop ¹⁾ | 0 | Execute positioning |
| | | 1 | Stop axis with deceleration |
| 9 - 15 | Corresponds to the default Control word | x | |

1) This bit applies to all modes.

Extended status word

The bits in the status word reflect the status of the state machine (for a detailed description, see "Status word" on page 2798 and "State machine" on page 2799).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|--|-------|---|
| 0 - 9 | Corresponds to the default Status word | x | |
| 10 | Target reached, depending on bit 8 (Stop) in the Control word register | 0 | If Stop = 0 |
| | | | Target position not reached. |
| | | 1 | Target position reached |
| | | | If Stop = 1 |
| | | 0 | Axis decelerating |
| | | | 1 |
| 11 | Corresponds to the default Status word | x | |
| 12 | Setpoint acknowledge | 0 | Ramp generator did not apply the position value |
| | | 1 | Ramp generator applied the position value |
| 13 - 15 | Corresponds to the default Status word | x | |

Position setting

The target position can be defined in 2 different ways:

| Type of setpoint definition | Description |
|-----------------------------|---|
| Single setpoint | After the target position is reached, Bit <i>Target reached</i> in register "Status word" on page 2794 is set. Then a new target position is defined. The drive stops at each target position before starting the movement to the next target position. |
| Set of setpoints | After the target position has been reached, the movement to the next target position is started immediately without stopping the drive. It is therefore possible to initiate a new positioning by specifying another target position during active positioning. |

The two modes "Single setpoint" and "Set of setpoints" are controlled by the timing of bits *New setpoint* and *Change set immediately* in the "extended control word" on page 2790 and *Setpoint acknowledge* in register "Extended control word" on page 2790.

These bits can be used to create a Request-Response mechanism. This makes it possible to specify a target position while a previous position specification is still being processed.

Specifying the target position

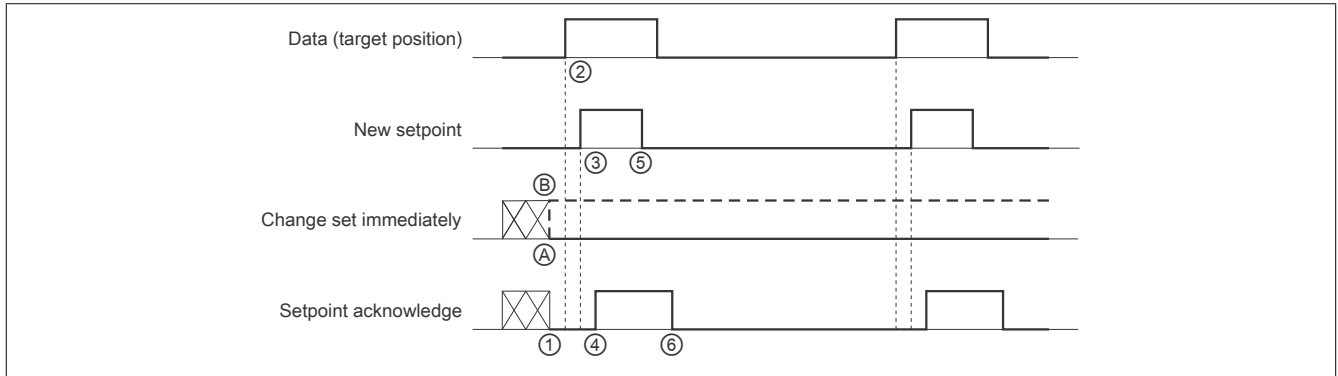

Figure 194: Principle for applying the setpoint

Transferring a new setpoint:

- 1) If bit *Setpoint acknowledge* in register "Extended status word" on page 2790 is 0, the module will accept a new target position.
- 2) The new target position is specified in register "Set position/speed" on page 2788.
- 3) A rising edge on bit *New setpoint* in the "extended control word" on page 2790 indicates that the new target position in register "Set position/speed" on page 2788 is valid and can be used for the next positioning movement.
- 4) After the module has received and saved the new target position, bit *Setpoint acknowledge* is set to 1 in register *Status word*.
- 5) Now the controller can reset the *New setpoint* bit to 0.
- 6) Then the module resets bit *Setpoint acknowledge* to 0 to signal when a new target position is accepted.

Position specification "Single setpoint"

When the *Change set immediately* bit is set to 0 (A in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This mechanism results in a speed of 0 when the motor reaches target position x_1 at time t_1 . After the controller has been notified that the setpoint has been reached, the next target position x_2 will be processed at time t_2 and reached at t_3 .

Figure 195: Ramp in *Single setpoint*

"Set of setpoints" preset position value

When the *Change set immediately* bit is set to 1 (B in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This means that the module receives the first target position at t_0 . A second target position is received at time t_1 . The drive immediately adapts the current movement to the new target position.

Figure 196: Ramp in *Set of setpoints*

Relative position setting

If bit *abs / rel* bit in register [Extended control word](#) is set, then the target position is interpreted as a relative value. At each *New setpoint* trigger, the target position will be increased by this value (or decreased if the value is negative).

If the mode changes between the position settings, relative movement will then proceed starting at the last specified position. The position setpoint mode is initialized with 0 when the module is started.

Mode 2: Speed mode - Constant speed (pos./neg.)

The value in register ["Position/Speed"](#) on page 2788 is now interpreted as the speed setpoint (microsteps/ cycle).

Observing the maximum permissible acceleration, the motor moves with a ramp to the desired speed setpoint and maintains this speed until a new speed setpoint is specified.

Values are allowed within the range -65535 to 65535. When a value is entered outside of this range, it is readjusted to these limits.

Mode -120: Set home position

The current actual position is changed so that the position specified in register ["Position/Speed"](#) on page 2788 is the home position. If you then move to this position, the motor is at the home position.

The home position in register ["Home position"](#) on page 2795 is also set to this value.

Before this mode is called, the motor must be at a standstill and the home position must have been determined using ["Positive / negative homing"](#) mode. In order to set the position, the [State machine](#) must be in state "Operation enable".

Mode -121: Remaining distance mode (like mode 1)

The number of steps defined in register ["Fixed position A"](#) on page 2783 are added to the current position and the resulting position is approached at a rising/falling edge on digital input 3.

Advice:

Steps are not added to the target position, but rather to the current position at the moment the trigger occurs.

Negative values are also allowed for the offset defined in [Fixed position A](#).

New target positions are no longer accepted in register ["Position/Speed"](#) on page 2788 after the trigger event. There must first be a switch made to [mode 0](#) and then back to mode -121.

Bit "Target reached" in register ["Status word"](#) on page 2794 is not set to 1 until the end position (after the trigger event) has been reached.

The ["homing configuration"](#) on page 2785 determines whether a rising or falling edge of the digital input is used as a trigger.

The [Reversing loop](#) is not enabled in this mode (i.e. any configured values not equal to 0 are ignored).

Mode -122: Set actual position

The target position set in register ["Position/Speed"](#) on page 2788 is applied as the current actual position in the internal position counter if the state machine is in state "Operation enable".

Before this mode is started, the motor must be at a standstill and physically located at the point for which the position being set should be applied.

Mode -123: Move to the target position when the external input is set

The position setpoint set in register ["Position/Speed"](#) on page 2788 is moved on a rising edge of digital input 3.

A new position setpoint is not applied until another rising edge occurs on the corresponding digital input. This can also occur during the active positioning procedure and will be applied immediately.

Mode -124: Two-position mode

Positions [Fixed position A](#) and [Fixed position B](#) are defined in the acyclic registers.

Value 1 on digital input 3 moves to fixed position A. Value 0 moves to fixed position B. It is also possible to switch between the two during an active positioning movement.

Mode -125/-126: Move to fixed position X

The purpose of these modes is to enable a virtual switch from speed mode to position mode, which otherwise is not possible because of the shared use of the register for position and speed setpoints.

- Mode -125: "Fixed position A" on page 2783
- Mode -126: "Fixed position B" on page 2784

Mode -127/-128: Positive/Negative homing

Mode -127 and -128 are used to select which direction to move.

The motor must be at a standstill before switching from another mode to one of the homing modes.

If the referencing condition occurs, then the motor stops and the values of the position counter and ABR counter valid at the moment when the referencing condition occurs are written to the "Referenced zero position" on page 2795 register.

In the [referencing configuration](#) you must specify whether referencing should occur at low/high level on the digital input, during stall or unconditionally.

Homing via digital input

Case 1: Active referencing level not yet reached → Motor not yet at end position:

Movement continues at the referencing speed in the referencing direction until the active level for "Stop referencing" is on the input.

Case 2: Active referencing level already reached → Motor at end position:

Movement continues at the referencing speed against the referencing direction until the active level for "Stop referencing" is no longer at the digital input. Movement continues at homing speed in the homing direction until the active level for "homing-stop" is on the digital input again.

Referencing during stall

Movement continues in the referencing direction until a stall is detected. When a stall is detected, the value of the position counter is entered in the "Referenced zero position" on page 2795 register within one millisecond. The motor is then stopped abruptly (not using the deceleration ramp). However, it can take up to 25 ms to stop the motor because the ramp generator runs with a configurable internal cycle of up to 25 ms.

In this mode, the nominal current is always used instead of the maximum current, even in acceleration phases.

To test the responsiveness of this homing mode, the motor load value used for identifying a stall can be made visible in the status word.

Unconditional referencing (immediate)

Immediate referencing: The current values of the position counter and of the ABR counter are immediately entered in register "Homed zero position" on page 2795, no motor movement.)

Current position (cyclic)

Name:

AbsPos01ActVal

This cyclic register contains the current position.

Default: Value of the internal position counter, can be changed to ABR counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Status word

Name:

MpGenStatus01

The bits in this register reflect the state of the state machine. For a more detailed description, see "[Status word](#)" on page 2798 and "[State machine](#)" on page 2799.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|-----------------------|-------|---|
| 0 | Ready to switch on | x | |
| 1 | Switched on | x | |
| 2 | Operation enabled | x | |
| 3 | Fault (error bit) | x | |
| 4 | Voltage enabled | x | |
| 5 | Quick stop | x | |
| 6 | Switch on disabled | x | |
| 7 | Warning | x | |
| 8 | Reserved | 0 | |
| 9 | Remote | 1 | Always 1 since there is no local mode for the SM module |
| 10 | Target reached | x | |
| 11 | Internal limit active | 0 | No limit violation |
| | | 1 | Internal limit is active (upper or lower software limit violated) |
| 12 | Mode-specific | x | |
| 13 - 15 | Reserved | 0 | Always 0 |

Input status

Name:

InputStatus

This register indicates the logical states of digital inputs.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|-----------------|--------|---------------------------------|
| 0 | Digital input 1 | 0 or 1 | Input state - Digital input 1 |
| ... | | ... | |
| 3 | Digital input 4 | 0 or 1 | Input state - Digital input 4 |
| 4 | Open circuit 1 | 0 | No error |
| | | 1 | Open circuit on digital input 1 |
| ... | | ... | |
| 7 | Open circuit 4 | 0 | No error |
| | | 1 | Open circuit on digital input 4 |

Motor identification

Name:

Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. After successful measurement, this register contains the time [µs] required to apply a current increase of $\Delta I = 1 \text{ A}$ to a motor winding.

This depends on:

- Operating voltage
- Inductance and resistance of the motor winding

| Notes | |
|-------|---|
| 1) | To achieve reproducible results, the measurement must be made under the following defined conditions: |
| a) | Motor is at standstill. |
| b) | The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: <ul style="list-style-type: none"> • Full steps are divisible by 4. • Microsteps = 0 |
| 2) | Condition 1b) is fulfilled after a the SM module is reset or switched on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application. |
| 3) | The current range from approximately 1/3 of the nominal current up to the nominal current is used as operating range for determining the motor identifier. |

| Data type | Motor ID values | Explanation |
|-----------|-----------------|--|
| UINT | 0 | No motor identifier available (after switching on for as long as the measurement conditions are not met) |
| | 1 to 32767 | Valid range of values for the motor ID register (in µs) |
| | 65534 | Invalid value: Overflow |

Homed zero position

Name:

RefPos01CyclicCounter

RefPos01AcyclicCounter

After a homing procedure, the homing point for the cyclic or acyclic position counter can be read back with these registers (either the internal position counter or ABR counter depending on bit 14 of register "[Control word](#)" on [page 2788](#)).

The following two registers are provided for the motor:

- Homed zero position for cyclic counter
- Homed zero position for acyclic counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Current position (acyclic)

Name:

AbsPos1ActValAcyclic

This acyclic register contains the current position.

Default: Value of the ABR counter, can be changed to internal position counter

| Data type | Values |
|-----------|---------------------------------|
| DINT | -2,147,483,648 to 2,147,483,647 |

Read back control word

Name:

ControlReadback01

This register can be used to read the contents of register "[Control word](#)" on [page 2788](#).

| Data type | Values |
|-----------|-------------|
| UINT | 0 to 65,535 |

Read back mode

Name:

ModeReadback01

This register can be used to read the contents of register "Mode" on page 2789.

| Data type | Values |
|-----------|-------------|
| SINT | -128 to 127 |

Error code

Name:

ErrorCode01

The cause of an error or warning can be read in this register.

| Data type | Error code | Error type | Priority | Description |
|-----------|------------|------------|----------|-----------------------------|
| UINT | 0x0000 | - | - | No error |
| | 0x3000 | Error | High | Voltage |
| | 0x4200 | Error | | Overtemperature |
| | 0xFF20 | Warning | : | Negative limit switch |
| | 0xFF21 | Warning | : | Positive limit switch |
| | 0x2300 | Warning | : | Overcurrent |
| | 0xFF00 | Warning | : | Current error ¹⁾ |
| | 0xFF01 | Warning | : | Stall ²⁾ |
| | 0xFF11 | Warning | Low | Open circuit |

1) A current error is only detected if bit 13 = 1 in the **control word** (current error detection enabled).

2) Stall is only detected if bit 15 = 1 in the **control word** (stall detection enabled).

Information regarding the handling of errors and warnings:

- Bit 3 (fault) and bit 8 (warning) in the **status word** can be used to query whether an error or a warning was reported in the error code register.
- Bit 7 (Fault Reset) and bit 8 (Warning Reset) in the **control word** are used to acknowledge pending errors and warnings.
- If two or more errors/warnings are pending, the one with the highest priority (the order in the table above) will be displayed in the error code register.

9.25.10.16.10.4 Operating function model "Ramp"

Control for this model has been based on the CANopen communication profile DS402.

Commands for controlling the modules are written to the "Control word" on page 2797. The current module state is returned in register "Status word" on page 2798. The function mode (absolute position, constant speed, homing, etc.) is set in register "Mode" on page 2789.

Control word

Control word bits and their state for the commands of the state machine:

| Command | Stall detection | Encoder position sync/async | Current error detection | Warning reset | Motor ID trigger | Reserved | CurrentControlEnable | Stop 2) | Fault reset | Mode-specific | Mode-specific | Mode-specific | Enable operation | Quick stop | Enable voltage | Switch on |
|-------------------|-----------------|-----------------------------|-------------------------|---------------|------------------|----------|----------------------|---------|-------------|---------------|---------------|---------------|------------------|------------|----------------|-----------|
| Bit ¹⁾ | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Shutdown | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 1 | 1 | 0 |
| Switch on | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | 0 | 1 | 1 | 1 |
| Disable voltage | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | x | 0 | x |
| Quick stop | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 0 | 1 | x |
| Disable operation | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | x | 0 | 1 | 1 |
| Enable operation | x | x | x | x | x | 0 | 0 | x | 0 | x | x | x | 1 | 1 | 1 | 1 |
| Fault reset | x | x | x | x | x | 0 | 0 | x | ↑ | x | x | x | x | x | x | x |

1) x ... Any, ↑ ... Rising edge

2) Bit 8 (stop) is only evaluated if the extended control word is enabled in register "General configuration" on page 2785.

| | |
|---|--|
| Bits 0, 1, 2, 3 and 7 (light gray in the previous table) | These bits control the state of the State machine according to the commands in the table above. |
| Stop | 0 ... Perform motor movement 1 ... Stop axis with deceleration This bit is only evaluated when the extended control word is enabled in register "General configuration" on page 2785. |
| Motor ID trigger | A rising edge enables the motor ID measurement. |
| Warning reset | A rising edge resets warnings (no effect on errors, which are reset using "Fault reset"; the state machine is not affected by this bit). |
| Fault reset | A rising edge resets errors and warnings (see "State machine" on page 2799) |
| Current error detection | 0 ... Current error detection disabled 1 ... Current error detection enabled |
| ABR counter sync/async | 0 ... Value of the ABR counter on register "Current position (acyclic)" on page 2795. Internal position counter of the ramp generator on register "Current position (cyclic)". 1 ... Value of the ABR counter on register "Current position (cyclic)" on page 2793. Internal position counter of the ramp generator on register "Current position (acyclic)". |
| Stall detection | 0 ... Stall detection disabled 1 ... Stall detection enabled |
| CurrentControlEnable | 0 ... Load-dependent current control disabled 1 ... Load-dependent current control enabled |

Status word

The individual bits of this register and its states depend on the current state of the state machine:

| Status | Reserved | Reserved | Reserved | Reserved | Int. limit active | Target reached | Remote | Reserved | Warning | Switch on disabled | Quick stop | Voltage enabled | Fault | Operation enabled | Switched on | Ready to switch on |
|------------------------|----------|----------|----------|----------|-------------------|----------------|--------|----------|---------|--------------------|------------|-----------------|-------|-------------------|-------------|--------------------|
| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Not ready to switch on | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 0 | 0 | 0 | 0 |
| Switch-on disabled | x | x | x | x | x | x | 1 | 0 | x | 1 | x | 0 | 0 | 0 | 0 | 0 |
| Ready to switch on | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 0 | 0 | 0 | 0 | 1 |
| Switched on | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 1 | 0 | 0 | 1 | 1 |
| Operation enable | x | x | x | x | x | x | 1 | 0 | x | 0 | 1 | 1 | 0 | 1 | 1 | 1 |
| Quick stop active | x | x | x | x | x | x | 1 | 0 | x | 0 | 0 | 1 | 0 | 1 | 1 | 1 |
| Fault reaction active | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 1 | 1 | 1 | 1 |
| Fault | x | x | x | x | x | x | 1 | 0 | x | 0 | x | 0 | 1 | 0 | 0 | 0 |

Information about the status word:

| | | |
|---|--|--|
| Bits 0, 1, 2, 3, 5 and 6 (light gray in the previous table) | These bits are set according to the current state of the State machine . | |
| Voltage enabled | Becomes 1 as soon as the motor is powered | |
| Warning | Becomes 1 if a warning is detected ("Overcurrent", "Undercurrent"). The type of warning is indicated in register " Error code " on page 2796. The highest priority error / warning is shown in each case, with the priority corresponding to the order in the respective table. Warnings can be reset with a rising edge on the "Warning reset" bit in the control word. | |
| Remote | Always 1 since there is no local mode on the SM module | |
| Target reached ¹⁾ , depending on bit 8 (Stop) in register Control word | <p>If Stop = 0</p> <p>In modes 1, -123, -124, -125 and -126 (absolute positioning): 0...Positioning begins 1...Target has been reached</p> <p>In mode 2 (constant speed): 0...Motor accelerates/brakes 1...Speed setpoint reached</p> <p>In modes -127 and -128 (homing): 0...Homing started 1...Homing ended</p> <p>In mode -122 (set actual position): The bit briefly becomes 0 and immediately becomes 1 again as soon as the position is set.</p> | <p>If Stop = 1</p> <p>In all modes: 0...Axis decelerating 1...Axis speed = 0</p> |
| Internal limit active | 0 ... No limit violation 1 ... Internal limit is active (upper/lower software limit violated) | |

1) If "Stop" has not been enabled in register "[General configuration](#)" on page 2785, then "Target reached" behaves the same as if Stop = 0.

State machine

The motor is controlled according to the state machine illustrated below. After the module is started, the state machine automatically changes to state "Not ready to switch on". The application then operates the state machine by writing commands to the [Control word](#).

The state machine successively reaches the states "Ready to switch on", "Switched on" and "Operation enable" by writing the consecutive commands "Shutdown", "Switch on" and "Enable operation".

Information:

Only in state "Operation enable" are motor movements executed according to the setting in register "Mode" on page 2789.

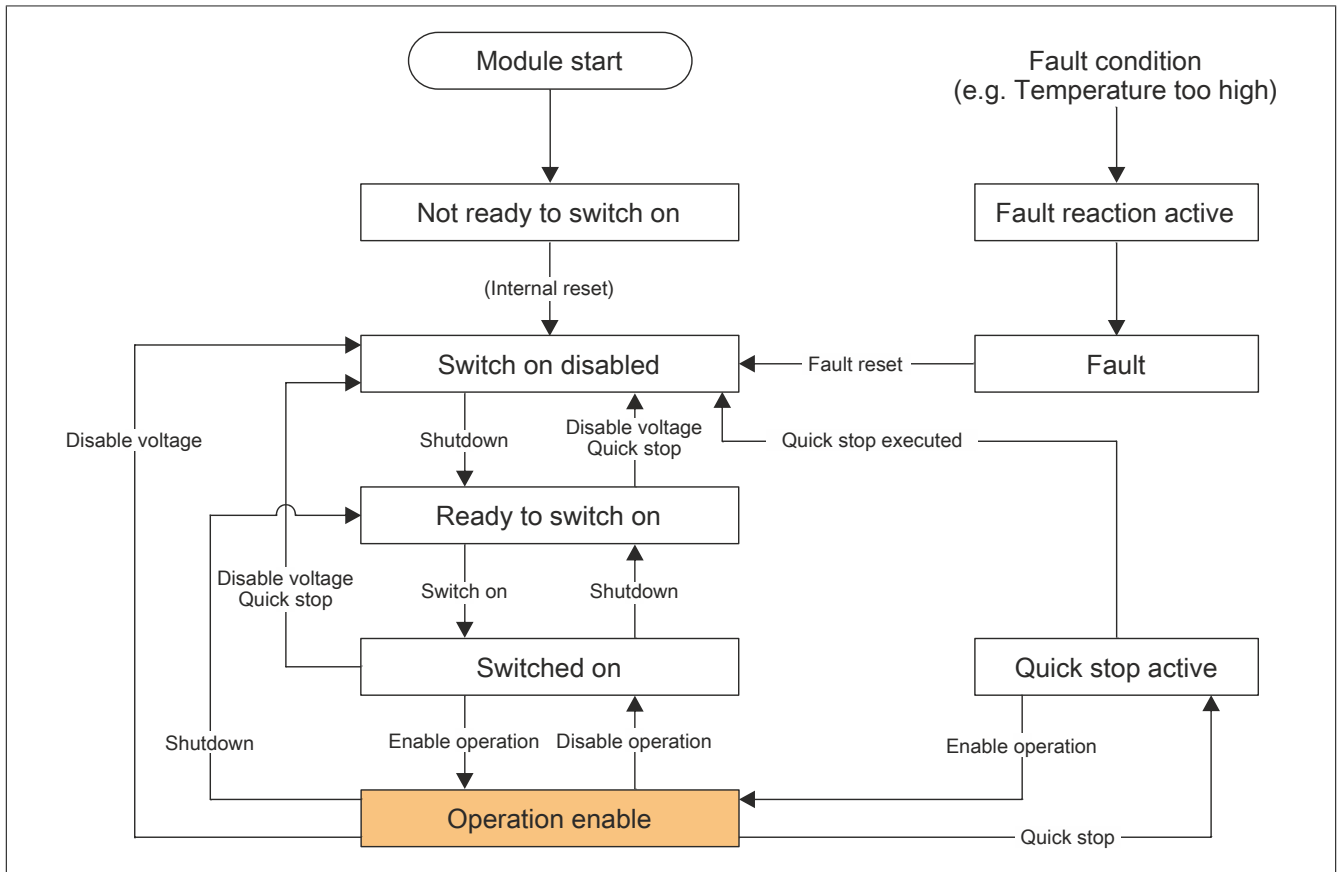

Figure 197: State machine - Flow chart

| State change | Description |
|--|--|
| Not ready to switch on → Switch on disabled | This state change occurs automatically after starting the module and internal initialization has taken place. |
| Switch-on disabled → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . No others actions are performed. |
| Ready to switch on → Switch-on disabled | This state change is brought on by the command <i>Disable voltage</i> or <i>Quick stop</i> . No others actions are performed. |
| Switched on → Switch-on disabled | This state change is brought on by the command <i>Disable voltage</i> or <i>Quick stop</i> . The motor voltage is cut off immediately. |
| Ready to switch on → Switched on | This state change is brought on by the <i>Switch on</i> command. The motor voltage is switched on. When this state change occurs for the first time since the module is started, the motor ID measurement is performed before state <i>Switched on</i> is achieved. This can take approximately 1 second. |
| Switched on → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . The motor voltage is cut off immediately. |
| Switched on → Operation enable | This state change is brought on by the <i>Enable operation</i> command. Motor movements are now performed depending on the set mode. |
| Operation enable → Switched on | This state change is brought on by the <i>Disable operation</i> command. If in motion, the motor is decelerated with the configured braking deceleration. The motor voltage remains switched on in state <i>Switched on</i> . |
| Operation enable → Ready to switch on | This state change is initiated by command <i>Shutdown</i> . The motor voltage is cut off immediately. |
| Operation enable → Switch on disabled | This state change is brought on by the <i>Disable voltage</i> command. Motor voltage switched off. It is strongly recommended to only make this state change on a stopped motor since regeneration on a motor running at no load can cause an overvoltage error on the DC bus (0x3210). |
| Operation enable → Quick stop active | This state change is brought on by the <i>Quick stop</i> command. If in motion, the motor is decelerated with the configured braking deceleration. During the deceleration, the state machine remains in state <i>Quick stop active</i> . If the motor comes to standstill, the switch to state <i>Switch on disabled</i> takes place automatically. While the state machine is in state <i>Quick stop active</i> , command <i>Enable operation</i> can be used to switch it back to state <i>Operation enable</i> . |
| → Fault reaction active | This state change is brought on when an error occurs and cannot be triggered by a command from the user. It can be triggered by error types classified as an "Error" (see "Error code" on page 2796). (The other error types classified as "Warning" only cause the "Warning" bit to be set in the status word and do not cause a state change of the state machine.) The motor voltage is cut off and the state machine immediately changes to state <i>Fault</i> . The error code register contains the error type (see table in "Error code" on page 2796). The highest priority error is shown. The priority corresponds to the order in the error code table. |
| Fault → Switch-on disabled | This state change is brought on by the <i>Fault reset</i> command. However, the state only changes if no more errors are present when the command is written. All errors and warnings are reset. The error code register contains 0 or the warning code if a warning is still present. |

Table 530: State machine - State change

9.25.10.16.11 NetTime Technology

For a description of NetTime Technology, see ["NetTime Technology" on page 3035](#).

9.25.10.16.12 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time | |
|---------------------------|--------|
| Function model "Standard" | 400 µs |
| Function model "Ramp" | 400 µs |

9.25.10.16.13 Minimum I/O update time

The minimum I/O update time specifies how far the bus cycle can be reduced so that an I/O update is performed in each cycle.

| Minimum I/O update time | |
|---------------------------|--------|
| Function model "Standard" | 400 µs |
| Function model "Ramp" | |
| Inputs | 400 µs |
| Outputs ¹⁾ | 25 ms |

1) Depends on the configuration of the ["movement profile generator" on page 2785](#).

9.26 Other functions

The following modules are included in this module group:

- Multi-measurement transformers / synchronization modules
- Universal mixed modules and combination modules
- Diode array modules
- PWM modules
- IO-Link master modules
- Potential distribution modules
- Supply modules for potentiometers
- Condition monitoring modules
- Specialty modules

9.26.1 Summary

| Model number | Short description | Page |
|---------------|---|------|
| 0ACS100A.00-1 | Accelerometer, nominal sensitivity 100 mV/g, top exit | 3166 |
| 0ACS100A.90-1 | Accelerometer, nominal sensitivity 100 mV/g, side exit | 3169 |
| X20CM0985 | X20 digital and analog mixed module, multi-measurement transducer/ synchronization module, 5 digital outputs, 24 VDC, 0.5 A source, 1 relay, 1 A, changeover contact, 8 analog inputs, ± 480 V / 120 V, 16-bit converter resolution, 3 analog inputs 5 A / 1 A AC, 16-bit converter resolution, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x TB12 separately. | 2803 |
| X20CM0985-02 | X20 digital and analog mixed module, multi-measurement transducer / synchronization module, 5 digital outputs, 24 VDC, 0.5 A, source, 1 relay, 1 A, 8 analog inputs, ± 480 V / 120 V, 16-bit converter resolution, 3 analog inputs, 5 A / 1 A AC, 16-bit converter resolution, additional software functionalities, adapted to VDE guidelines (2018), order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x X20TB12 separately! | 2846 |
| X20CM0985-1 | X20 digital and analog mixed module, multi-measurement transducer / synchronization module, 5 digital outputs, 24 VDC, 0.5 A, source, 1 relay, 1 A, 8 analog inputs, ± 480 V / 120 V, 16-bit converter resolution, 3 analog inputs, 5 A / 1 A AC, 16-bit converter resolution, additional software functionalities, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x X20TB12 separately! | 2921 |
| X20CM4323 | X20 PWM module, 4 digital outputs for switching electromechanical loads, 24 VDC, oversampling output functions, time-triggered output functions, NetTime function | 2992 |
| X20CM4800X | X20 analog input module, vibration measurement, 4 IEPE analog inputs, 50 kHz sampling frequency, 24-bit converter resolution | 3021 |
| X20CM4810 | X20 analog input module, for vibration measurement and analysis of condition monitoring tasks, 4 IEPE analog inputs, 51.5625 kHz sampling frequency, 24-bit converter resolution | 3039 |
| X20CM6209 | X20 diode array module, 1 A, 40 V reverse voltage, no module status data | 3174 |
| X20CM8281 | X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ± 10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ± 10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement | 3178 |
| X20CM8323 | X20 PWM module, 8 digital outputs for switching electromechanical loads, 0.6 A continuous current, 2 A peak current, current monitoring, switching time detection | 3197 |
| X20CMR010 | X20 cabinet monitoring module, integrated temperature and humidity sensor, production data acquisition, 512 kB flash memory for user data | 3216 |
| X20CMR100 | X20 cabinet monitoring module, integrated temperature and humidity sensor, production data acquisition, integrated Technology Guard | 3230 |
| X20CMR111 | X20 cabinet monitoring module, integrated temperature sensor, moisture sensor and accelerometer, production data acquisition, 2 inputs for external PT1000, 2 digital inputs 24 V, 1 digital output 24 V, 0.5 A, 512 kB flash memory for user data, integrated Technology Guard | 3242 |
| X20DS4387 | X20 digital signal module, 4x IO-Link master, 4 digital channels configurable as inputs or outputs, 3-wire connections | 3269 |
| X20DS438A | X20 digital signal module, 4x IO-Link master V1.1, 4 digital channels configurable as inputs or outputs, 3-wire connections, NetTime function | 3287 |
| X20PD0011 | X20 potential distributor module, 12x GND, integrated microfuse | 3327 |
| X20PD0012 | X20 potential distributor module, 12x 24 VDC, integrated microfuse | 3332 |
| X20PD0016 | X20 potential distributor module, 5x GND, 5x 24 VDC, each with 1x floating feed, integrated microfuse | 3337 |
| X20PD2113 | X20 potential distributor module, 6x GND, 6x 24 VDC, with feed option, integrated microfuse | 3343 |
| X20PS4951 | X20 power supply module, for potentiometers, 4x ± 10 V for potentiometer supply | 3349 |
| X20cCM0985-1 | X20 digital and analog mixed module, coated, multi-measurement transducer / synchronization module, 5 digital outputs, 24 VDC, 0.5 A, source, 1 relay, 1 A, 8 analog inputs, ± 480 V / 120 V, 16-bit converter resolution, 3 analog inputs, 5 A / 1 A AC, 16-bit converter resolution, additional software functionalities, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x X20TB12 separately! | 2921 |
| X20cCM4810 | X20 analog input module, coated, for vibration measurement and analysis of condition monitoring tasks, 4 IEPE analog inputs, 51.5625 kHz sampling frequency, 24-bit converter resolution | 3039 |
| X20cDS438A | X20 digital signal module, coated, 4x IO-Link master V1.1, 4 digital channels configurable as inputs or outputs, 3-wire connections, NetTime function | 3287 |
| X20cPD2113 | X20 potential distributor, coated, 6x GND, 6x 24 VDC, with supply option, integrated microfuse | 3343 |

9.26.2 X20CM0985

Data sheet version: 1.30

9.26.2.1 General information

The module has a compact size and combines a power measurement module that has special features with a synchronization unit that is able to meet all demands.

The measurement unit's 3 current inputs are suitable for both X: 1 A and X: 5 A current transformers. Overcurrent resistance and the high resolution of the measurement unit round off its features. For the voltage inputs, the value range can be configured between 480 VAC and 120 VAC.

The area of use includes 4-wire AC networks with a phase voltage up to 480 VAC and 3-wire systems, whereas L2 can be grounded (V-connection). The module can also handle Aron measuring circuits.

The resulting measured values include the pure phase current; line-to-line voltage or phase voltage; the effective, reactive and apparent power parts; the mains frequency; the power factor and much more. In addition, peak values and energy meters are stored on the module in nonvolatile memory. Depending on the configuration, it is also possible to use a digital output as a pulse encoder for an external energy meter.

The synchronization unit doesn't just take the phasing and phase voltage into consideration; integrated intelligence also monitors the rate of change and other parameters, allowing them to influence when the synchronization output is switched. It is also possible to monitor a generator using a large number of additional conditions. A total of 4 voltage inputs provide substantial overall flexibility.

Monitoring functions expand the features of the module. Rating-dependent overcurrent monitoring is included, which utilizes the thermal capacity of the motor/generator to allow short overloads while still providing full protection. The dependent, delayed imbalanced load monitoring used to protect three-phase generator and three-phase networks from imbalanced load can be adapted to the characteristics of different generator types using parameters while taking their special thermal time constants into account.

- Energy measurement for 120 to 480 VAC
- Simultaneous measurement of 2 AC mains networks plus 2 additional voltages
- For multifunctional measurement tasks
- Intelligent mains synchronization unit

Information:

Please refer to section "[Safety guidelines](#)" on page 2806 before operating the module.

9.26.2.2 Order data

| Model number | Short description | Figure |
|--------------|--|---|
| | Other functions |  |
| X20CM0985 | X20 digital and analog mixed module, multi-measurement transducer/ synchronization module, 5 digital outputs, 24 VDC, 0.5 A source, 1 relay, 1 A, changeover contact, 8 analog inputs, ± 480 V / 120 V, 16-bit converter resolution, 3 analog inputs 5 A / 1 A AC, 16-bit converter resolution, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x TB12 separately. | |

9.26.2.4 Safety guidelines

General information

Programmable logic controllers, operating/monitoring devices (e.g. industrial PCs, Power Panels, Mobile Panels, etc.) as well as uninterruptible power supplies have all been designed, developed and manufactured by B&R for conventional use or for use with increased safety requirements (safety technology) in industry. They were not designed, developed and manufactured for any use involving serious risks or hazards that could lead to death, injury, serious physical damage or loss of any kind without the implementation of exceptionally stringent safety precautions. In particular, such risks and hazards include the use of these devices to monitor nuclear reactions in nuclear power plants, their use in flight control or flight safety systems as well as in the control of mass transportation systems, medical life support systems or weapons systems.

When using programmable logic controllers or operating/monitoring devices as control systems together with a Soft PLC (e.g. B&R Automation Runtime or comparable product) or Slot PLC (e.g. B&R LS251 comparable product), safety precautions relevant to industrial control systems (e.g. the provision of safety devices such as emergency stop circuits, etc.) must be observed in accordance with applicable national and international regulations. The same applies for all other devices connected to the system, e.g. drives.

All tasks such as the installation, commissioning and servicing of devices are only permitted to be carried out by qualified personnel. Qualified personnel are those familiar with the transport, mounting, installation, commissioning and operation of devices who also have the appropriate qualifications (e.g. IEC 60364-1). National accident prevention regulations must be observed.

The safety notices, connection descriptions (type plate and documentation) and limit values listed in the technical data are to be read carefully before installation and commissioning and must be observed.

Intended use

Danger!

Electronic devices are never completely failsafe. If the multi-measurement and synchronization unit fails, the user is responsible for making sure that the motor or generator is brought to a secure state.

Some errors are detected and prevented in the synchronization unit by the system's internal software monitoring. However, when the device is in operation it is always possible for errors, defective components, software errors or configuration mistakes to occur at any time. B&R emphasizes that the multi-measurement and synchronization unit possesses neither a failsafe function nor a redundancy system. For this reason, independent higher-level safety precautions need to be put in place to ensure that personnel and machines are protected.

Grounding the Mounting Rail

For grounding purposes, a good conductive connection between the mounting rail and the metal back wall is required. The mounting rail is to be connected conductively to the back wall. This is achieved by inserting a contact washer with the fastening screw.

Information:

The control cabinet back wall must be connected with GND

9.26.2.5 LED status indicators

For a description of the various operating modes, see "[Diagnostic LEDs](#)" on page 3787.

LED status indicators - Right

| Figure | LED | Color | Status | Description |
|---|-------|-----------------------------|------------------|---|
|  | r | Green | Off | No power to module |
| | | | Single flash | RESET mode |
| | | | Double flash | BOOT mode (during firmware update) ¹⁾ |
| | | | Blinking | PREOPERATIONAL mode |
| | | | On | RUN mode |
| | e | Red | Off | No power to module or everything OK |
| | | | On | Error or reset status |
| | e + r | Red on / Green single flash | Invalid firmware | |
| | 1 - 6 | Orange | | Output status of the corresponding digital output |

1) Depending on the configuration, a firmware update can take up to several minutes.

Status-LEDs right

| Figure | LED ¹⁾ | Terminal | Color | Status | Description |
|---|-------------------|----------|-------|--------|----------------------------|
|  | 1 | X3 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 2 | X4 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 3 | X5 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 4 | X6 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 5 | X2 | Green | On | Measurement range: 1 A |
| | | | Red | On | Measurement range: 5 A |

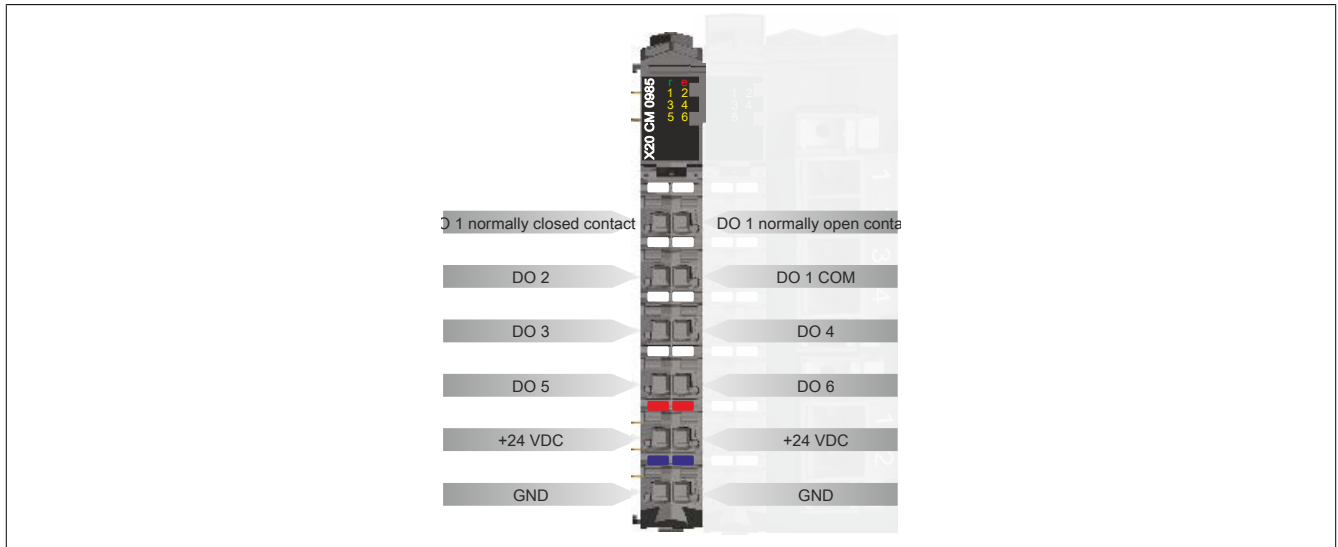

1) LEDs 1 - 5 are green/red dual LEDs.

9.26.2.6 Connection elements

9.26.2.7 Digital outputs X1

The X1 and X2 terminals can each be keyed differently to prevent them from being inadvertently plugged into the module incorrectly.

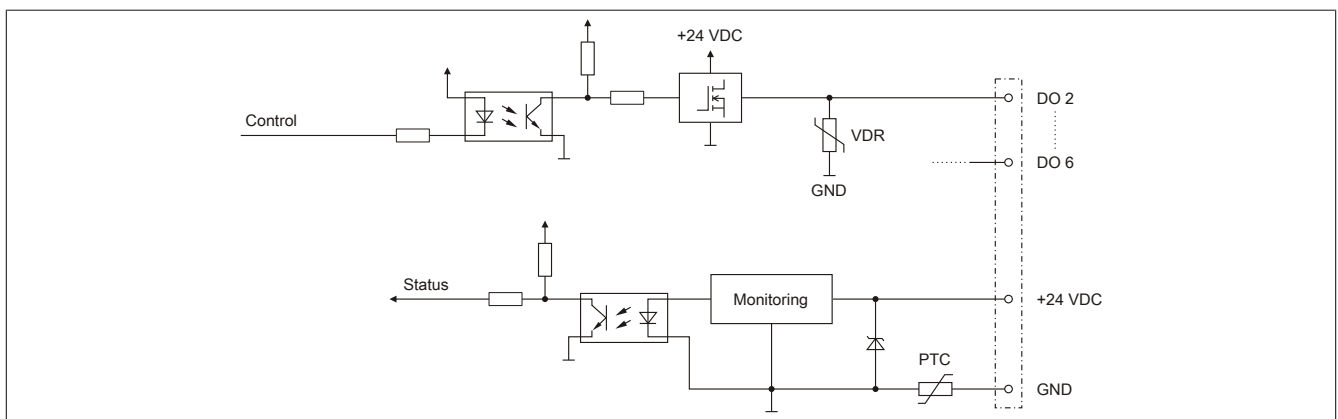

Function description of the digital outputs

| Digital output | Description |
|----------------|--|
| DO1 | This digital output is designed as a changeover contact switch. The monitoring relay allows selective monitoring of: <ul style="list-style-type: none"> • Overvoltage and undervoltage • Overfrequency and underfrequency • Voltage asymmetry • Current asymmetry • Calculated neutral conductor current (maximum) • Short circuit current • Rating-dependent overcurrent • Limit value of the capacitive reactive power (exciter failure) |
| DO2 | DO2 serves as a meter output. The generated pulses can be recorded by an external energy meter (kWh). |
| DO3 | This output is set when there is no voltage on the bus bar (below the lower limit of the defined parameter). 3-phase monitoring takes place for the bus bar voltage. |
| DO4 | DO4 serves as a synchronization pulse. The power switch is activated by setting this output. The output is deactivated after the configured time has elapsed (exception: "Synchro check" operating mode). |
| DO5 and DO6 | These outputs are freely available to the user. |

DO1 - Output circuit diagram

DO2 - DO 6 - Output circuit diagram

9.26.2.8 X2 analog current inputs

The X2 terminal measures the three phase currents of the generator mains using an externally connected current transformer. The measurement range of the current inputs can be configured as 1 A or 5 A.

Terminals X1 and X2 can be keyed differently to prevent unintentional incorrect connection on the module.

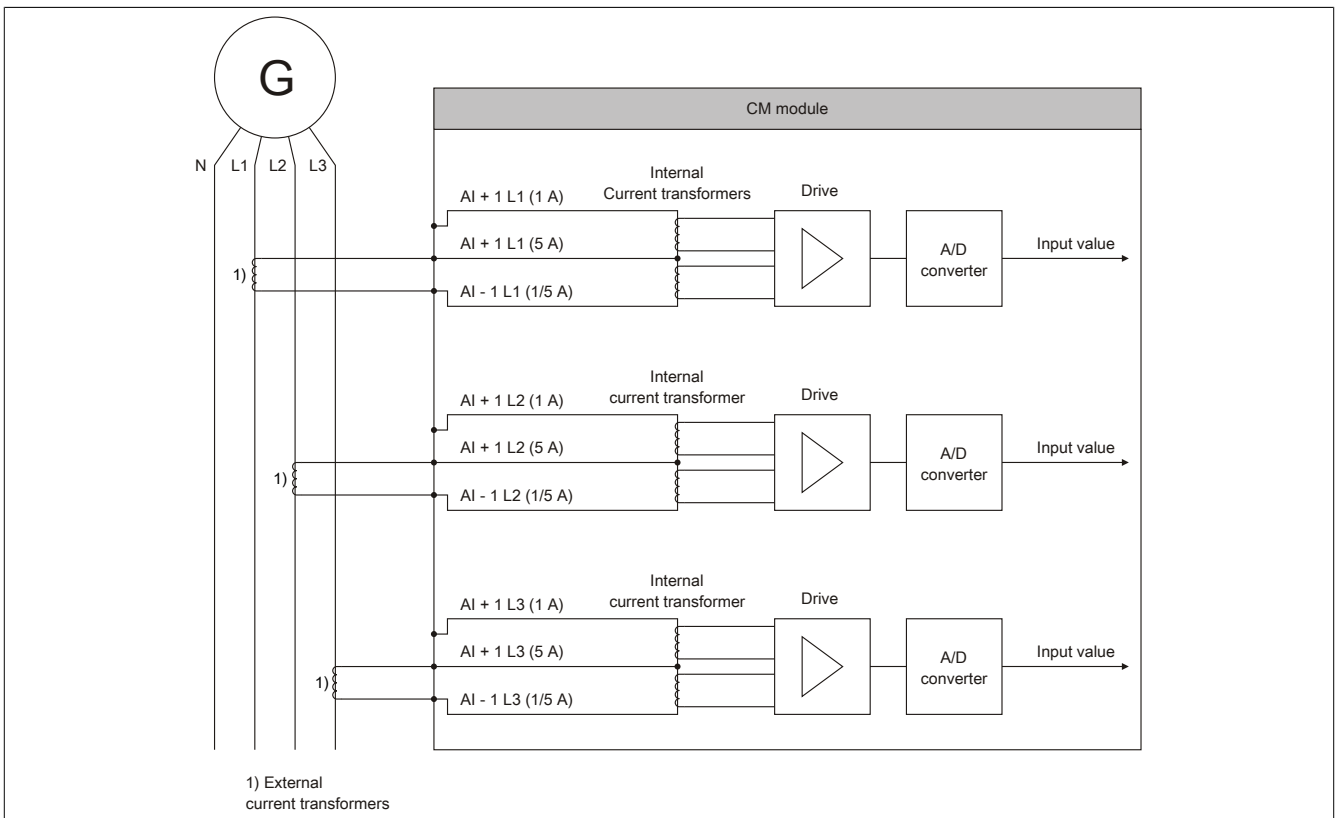

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

Input circuit diagram - Analog current inputs

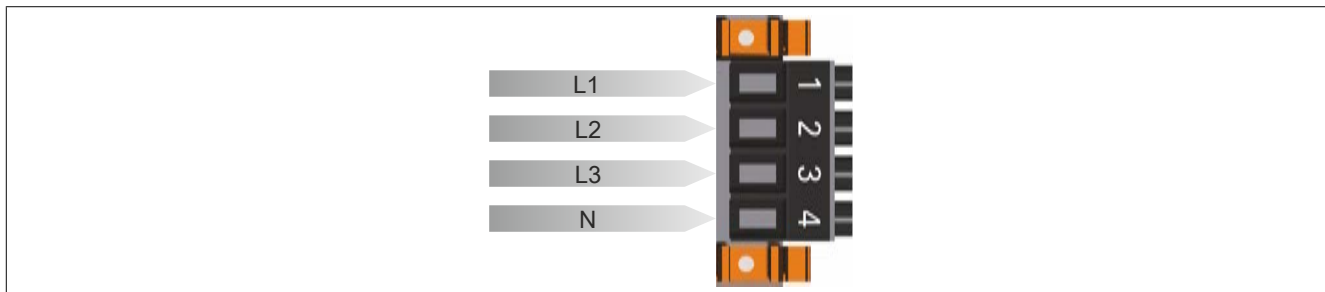

9.26.2.9 X3 and X5 analog voltage inputs

The X3 and X5 terminals are used to measure and monitor the line-to-line and phase voltages of the generator mains and bus bar.

- Terminal X3: Generator mains
- Terminal X5: Bus bar

Terminals X3 and X5 are keyed differently to prevent unintentional incorrect connection on the module. Section ["Releasing the locking clip for terminals X3 - X6" on page 2816](#) describes how to release the terminal locking clip.

9.26.2.10 X4 and X6 analog voltage inputs

The voltage inputs on the X4 and X6 terminals are used to determine the line-to-line voltages for synchronization between two different mains networks.

- Terminal X4: Synchronization mains network 1
- Terminal X6: Synchronization mains network 2

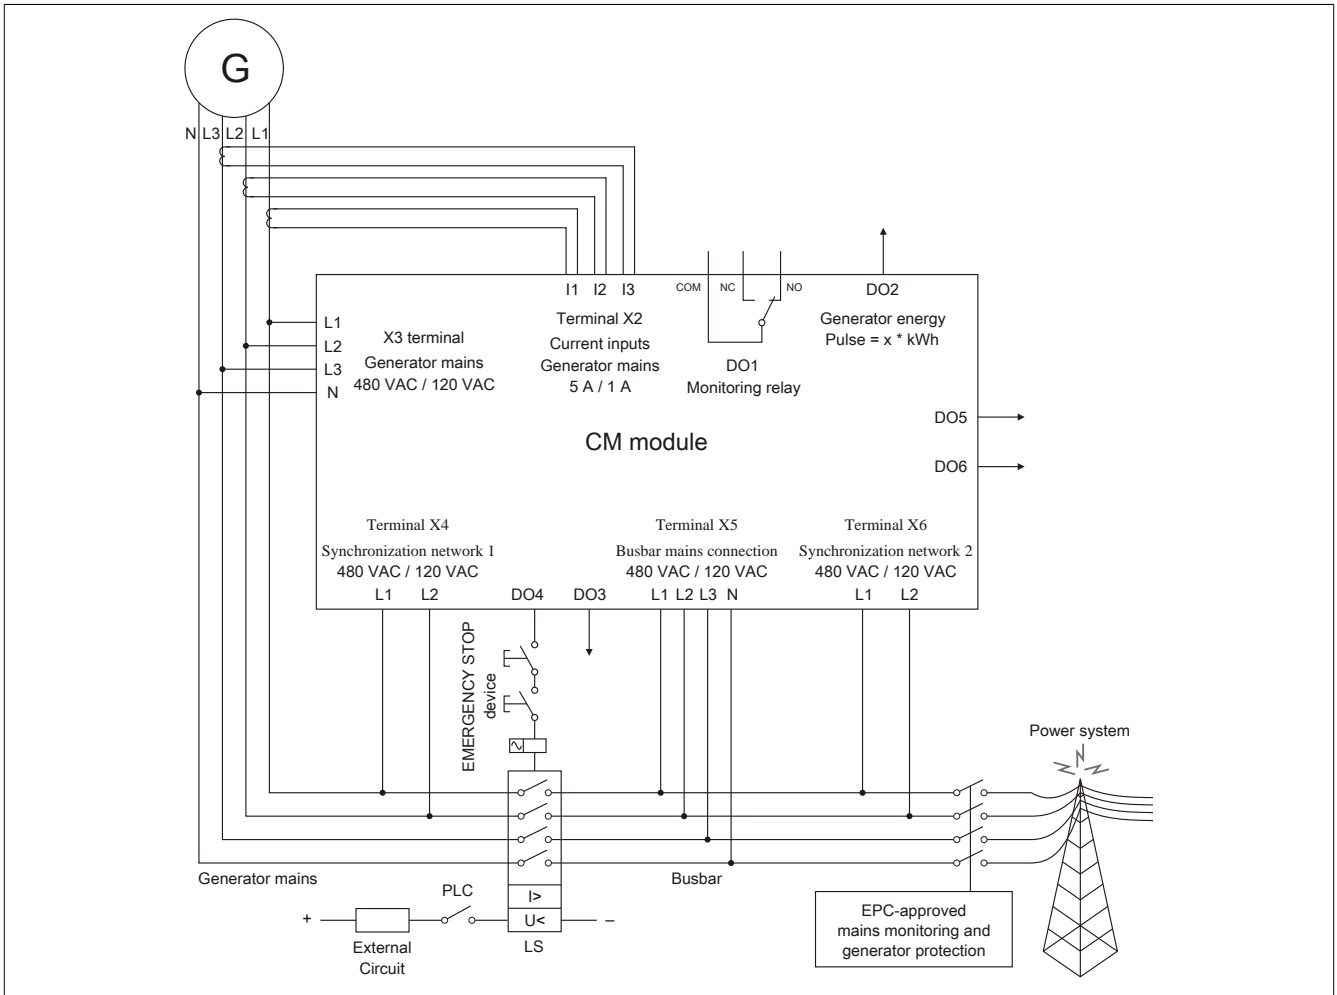

The X4 and X6 terminals are each keyed differently to prevent them from being inadvertently plugged into the module incorrectly. Section ["Releasing the locking clip for terminals X3 - X6" on page 2816](#) describes how to release the terminal locking clip.

Input circuit diagram, analog voltage inputs

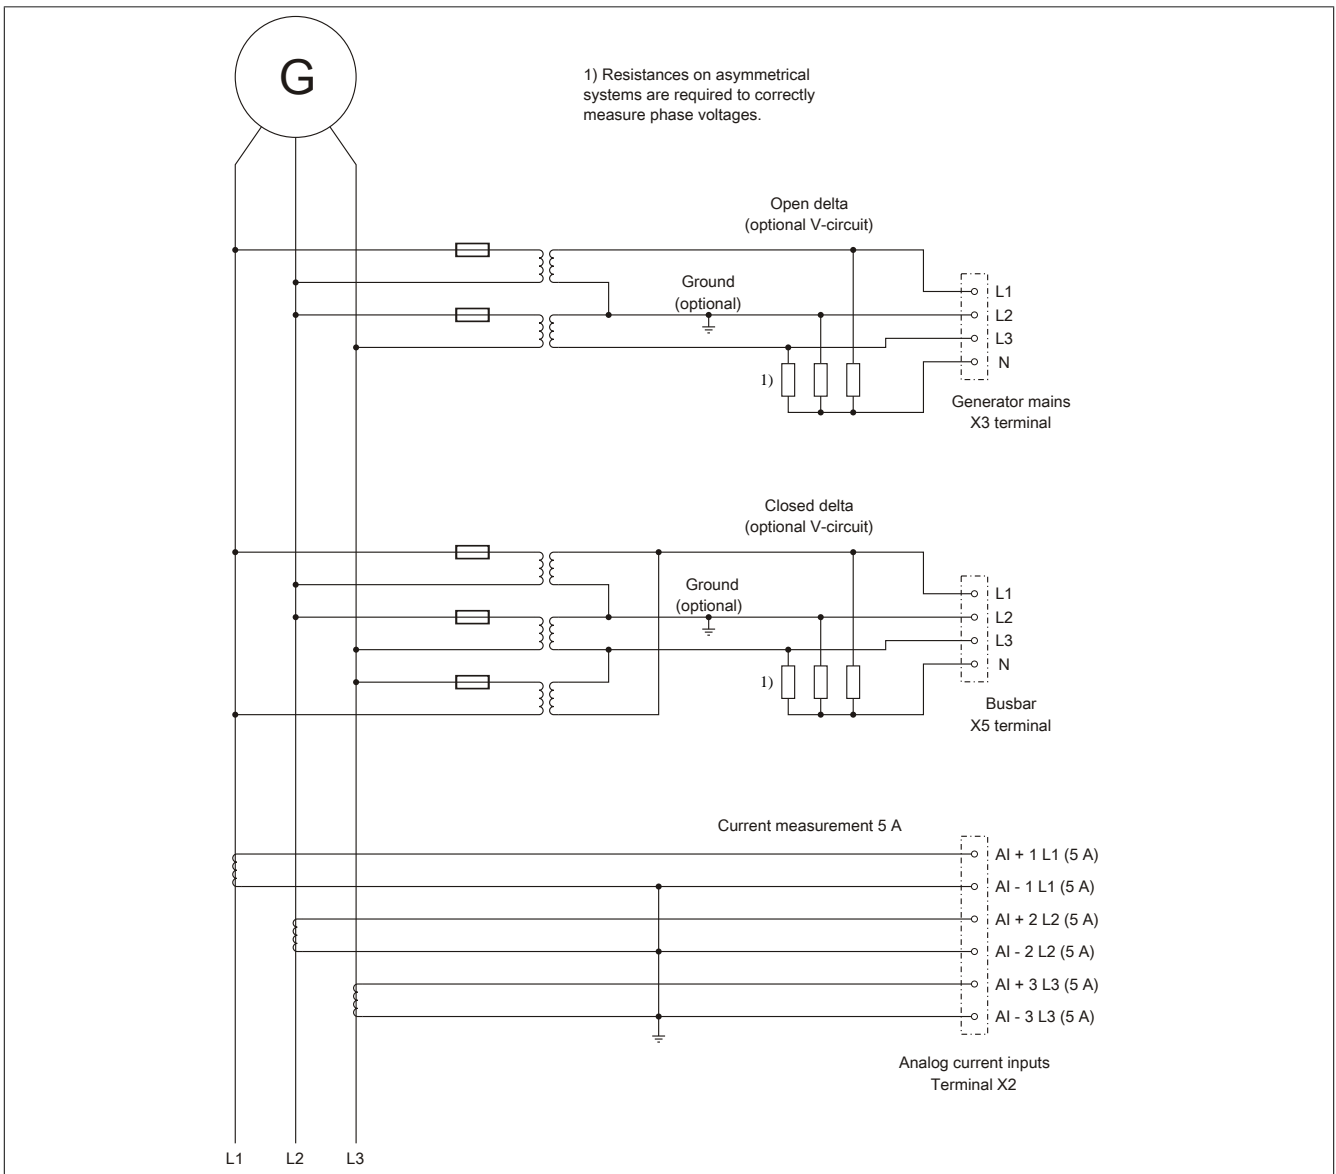

9.26.2.11 Circuit diagram

9.26.2.12 Typical connection examples for voltage/current measurement

For power measurement, the X3 terminal must always be used in connection with the X2 terminal! For single-phase measurement, always ensure that current input 1 is used for power measurement if voltage input 1 is being used. Otherwise, accurate power measurement is not possible for this phase!

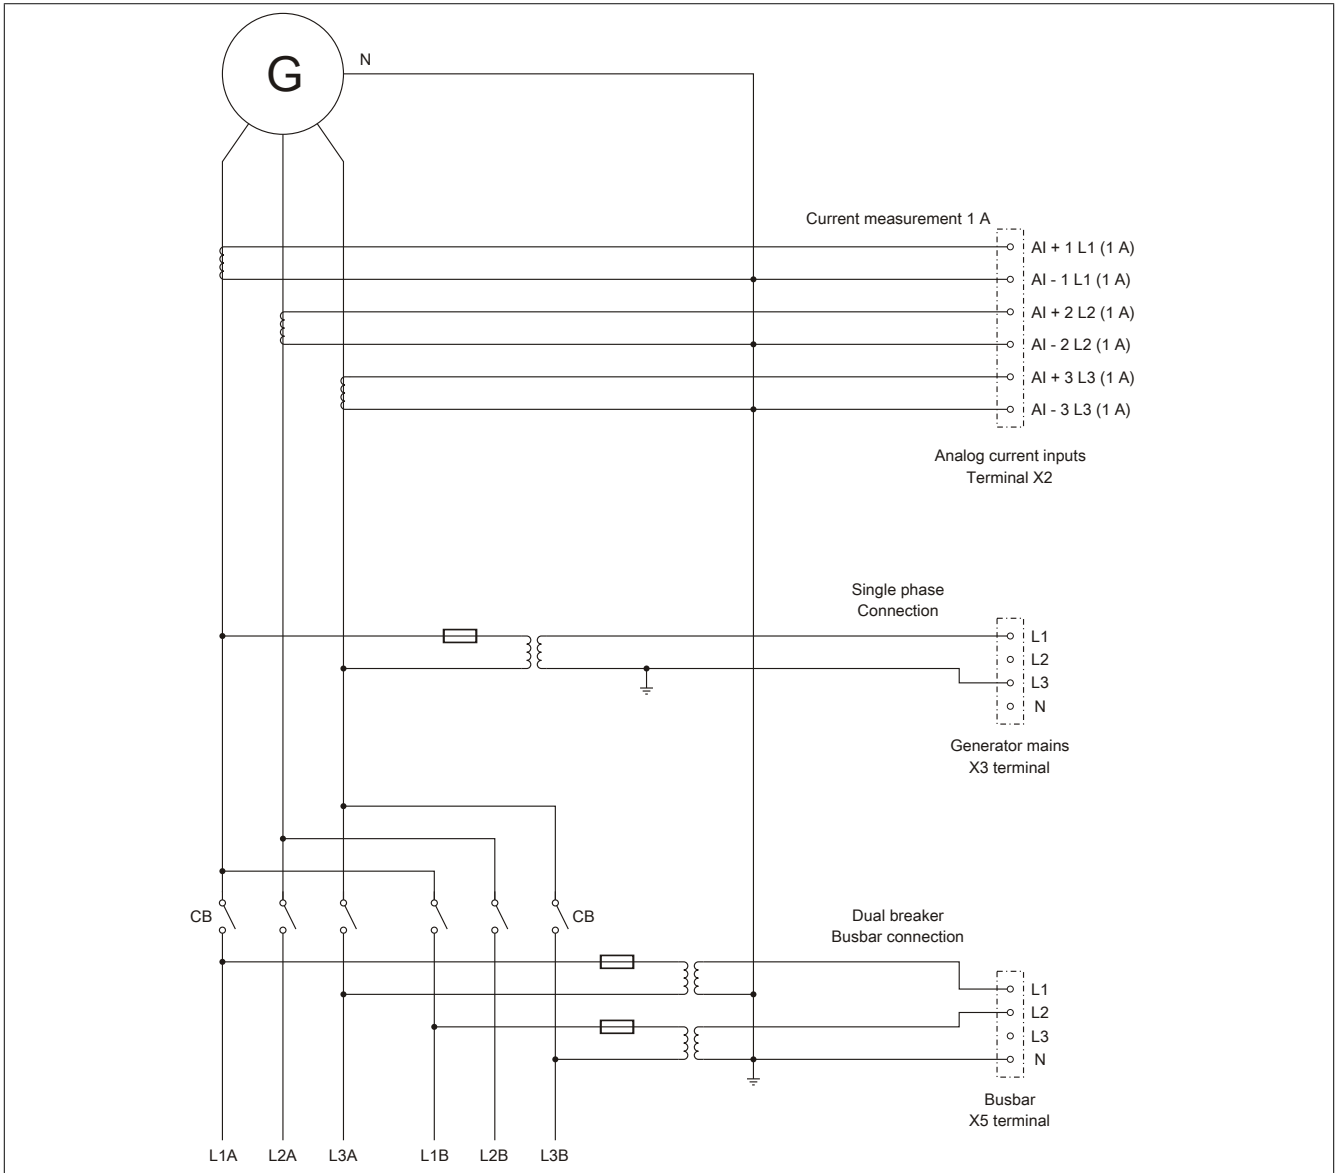

Connection example 1

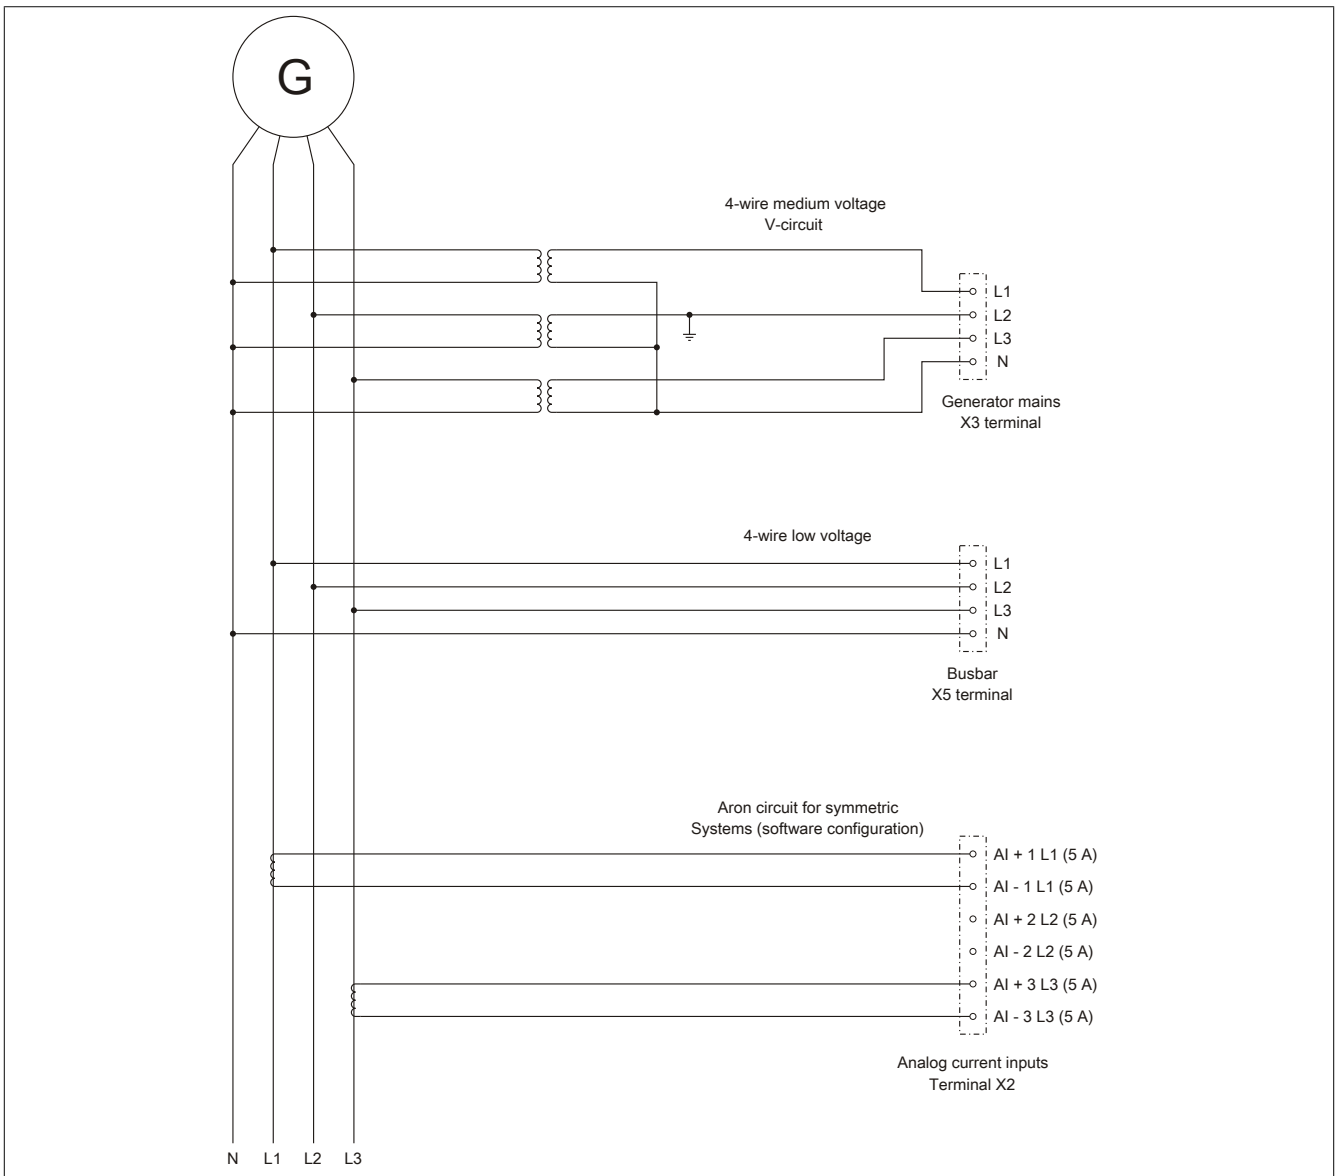

Connection example 2

Connection example 3

Connection example 4

9.26.2.13 Electrical service life

The electrical service life for the DO1 relay output can be seen in the following diagram.

9.26.2.14 Releasing the locking clip for terminals X3 - X6

Terminals X3 - X6 are equipped with a terminal locking clip. This clip attaches the terminal block securely to the electronic module. This prevents the terminal from accidentally being disconnected.

To release the locking clip, press inwards on the corrugated part of the lever with your fingertip (1) and then slide outwards (2). No additional tools are required for removing the terminal.

Terminals X5 and X6 must be removed first before terminals X3 and X4 can be removed.

9.26.2.15 Synchronization functions

The following three synchronization functions are available on the module:

- ["Synchronization with slip" on page 2816](#)
- ["Synchro check" on page 2817](#)
- ["Switching to voltage-free "dead bus"" on page 2817](#)

Synchronization with slip

The following is valid for synchronization mains 1 and synchronization mains 2:

- $50\% < U < 125\%$ of the nominal voltage U_N
- $80\% < f < 110\%$ of the nominal frequency f_N

The generator voltage is adjusted to the synchronization voltage with regard to amplitude and frequency. Taking into account the configured phase angle ($\Delta\alpha$), a defined transformer vector group and the switching response time, the switch-on command is calculated and transmitted in advance so that the main contacts of the power switch are closed at the point of synchronicity.

Synchronization occurs under the following conditions:

- The "Synchronization selection" command is set using a software application
- The device is ready.
- The configured limit for voltage difference is not exceeded (ΔU_{\max}).
- The configured limits for frequency difference are not exceeded (Δf_{\max} and Δf_{\min}).
- The configured limit for the phase angle (including vector group transformer $\Delta\alpha$) is not exceeded (j_{\max}).

The actual synchronization is "authorized" if the condition for the phase angle is met the first time and the phase window is exited once. It should be noted that the conditions for voltage and frequency difference do not yet have to be fulfilled this first time.

This means that if the phase difference happens to lie within the phase window when the request is made, it is not necessary to re-enter the window for this "authorization" to take place. In order to abort synchronization when in an "authorized" state, the "Synchronization with slip" command must be reset.

After the synchronization command has been authorized, the synchronization window of all the aforementioned synchronization conditions must be entered again from any phase angle in order to obtain a synchronization impulse in accordance with the switch lead time.

At very low frequencies or equivalent frequencies and in adherence to the conditions described above, synchronization will also take place when entering the synchronization window a second time. The synchronization impulse is only issued at a phase angle = 0° , however.

At low differential frequencies, the switch is not immediately engaged when the phase window is reached. This only occurs when synchronization is possible at the point of synchronicity.

DO4 changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

Synchro check

In this operating mode, the device can be used to check the synchronization. The DO4 output remains set as long as the following conditions are met:

- The "Enable Synchro Check" command is set using software.
- The device is ready.
- The configured limit for voltage difference is not exceeded (ΔU_{\max}).
- The configured limits for frequency difference are not exceeded (Δf_{\max} and Δf_{\min}).
- The defined limit for the phase angle is not exceeded (ϕ_{\max}).

DO4 stays at High as long as all conditions are met.

Switching to voltage-free "dead bus"

The switch-on command for the power switch is output without synchronization if the following conditions have been met:

- The "Enable Dead Bus" command is set using software.
- The device is ready.
- The bus bar does not have voltage applied: $U_B < U_{B\min}$ as a percentage of U_{NomBus}

| | |
|-------------------------|-------------------------|
| U_B ... | Bus bar phase voltage |
| $U_{B\min}$... | Minimum bus bar voltage |
| U_{NomBus} ... | Bus bar nominal voltage |

- The generator voltage and frequency can be any valid value.

DO4 changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

9.26.2.16 Measurement functions

Timing diagram

Measured parameters for generator mains (X3)

- Phase currents
- Current average
- Dynamic current average
- Neutral current
- Line-to-line voltages
- Phase voltages
- Voltage average
- Total apparent power
- Total reactive power
- Total active power
- Active power factor
- Frequency

Measured parameters between synchronization mains networks

- Differential angle
- Differential voltage

Rating-dependent overcurrent

Rating-dependent overcurrent monitoring is in accordance with the specifications of IEC 255-8 "Electrical relay; Relay for protecting against thermal overload (overload relay)" and IEC 255-17 "Electrical relay; Relay for protecting against the thermal overload of motors (overload relay for motors)".

Dependent delayed imbalanced load monitoring

Dependent delayed imbalanced load monitoring protects against imbalanced loads in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An imbalanced load can be caused by uneven current distribution in the mains due to imbalanced load, asymmetrical short circuits, line interruptions or switching operations. Imbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An imbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an imbalanced load occurs, the characteristics that trigger imbalanced load protection should be adapted to the thermal characteristics of the generator. Imbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

Short circuit current monitoring

If overcurrent or a short circuit occurs and the limit value is exceeded, the error message "Overcurrent / Short circuit" is signaled after the configured time delay has passed.

Voltage asymmetry monitoring

The trigger value, which is adjustable by percentage, is always based on the respective average voltage of the linked generator voltages. This value defines the maximum permitted deviation of one of the three differential voltages between the three monitored, interlinked phase voltages.

If this value is exceeded in either direction, the error notification "Asymmetrical voltage" is indicated after the configured time delay has passed.

Bus bar voltage measurement and zero voltage monitoring

3-phase monitoring takes place for the bus bar voltage. The measured values are represented as phase-to-phase and phase-to-neutral values. The DO3 output is set when there is no voltage (below the lower dead bus limit) on the bus bar (X5 terminal).

This monitoring can be used to determine which synchronization function should be used.

| Synchronization function | Bus bar voltage measurement |
|---------------------------|---|
| Dead bus | No voltage is being supplied to the bus bar or the value is below the lower limit parameter. Output DO3 is set. |
| Synchronization with slip | The voltage measured on the bus bar is above the defined parameter value. Output DO3 is not set. |

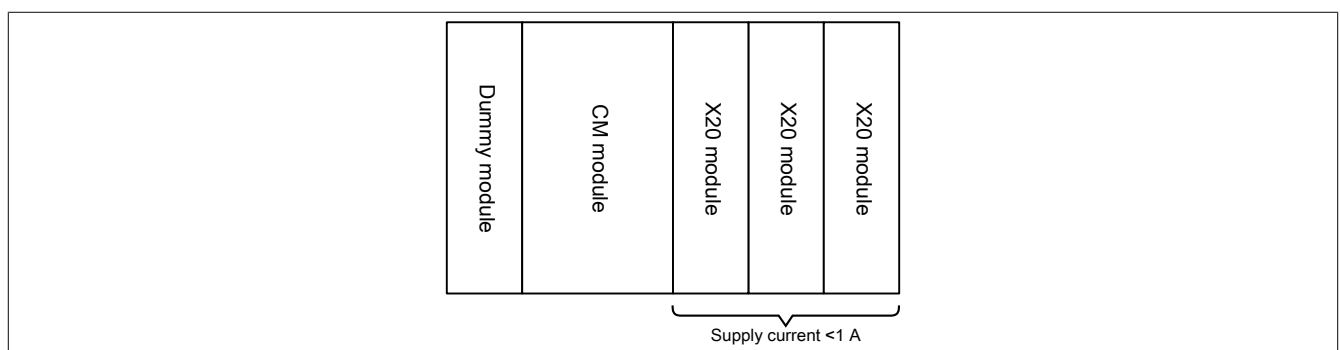

Exciter failure

The reactive power monitoring can be used to protect a generator against operating in the impermissible range. The capacitive reactive power monitor offers protection against under-excitation (exciter failure). If the lower limit is exceeded (in the negative direction), the error message "Exciter failure" is signaled after the configured time delay has passed.

9.26.2.17 Derating

Derating does not need to be taken into account for operation below 55°C.

For operation above 55°C, a dummy module must be connected to the left of the module. A maximum supply current of 1 A is permitted to pass through the module to the modules connected to the right.

9.26.2.18 Register description

9.26.2.18.1 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section ["General data points" on page 3790](#).

1) The offset specifies the position of the register within the CAN object.

9.26.2.18.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.2.18.3.2 CAN I/O bus controller

The module occupies 8 analog logical slots on CAN I/O.

9.26.2.18.4 Configuration registers**9.26.2.18.4.1 Generator mains****Nominal voltage of generator mains (U_{NomGen})**

Name:

ConfigOutput02

This is needed for converting the percentages based on this nominal value into physical units.

| Data type | Value | Information | Resolution |
|-----------|-------------|--|------------|
| UINT | 70 to 65000 | Corresponds to 70 to 65000 V. Bus controller default setting: 0 | 1 V |

Nominal current of generator mains (I_{Nom})

Name:

ConfigOutput04

This is needed for converting the percentages based on this nominal value into physical units.

| Data type | Value | Information | Resolution |
|-----------|------------|---|------------|
| UINT | 0 to 65000 | Corresponds to 0 to 65000 A. Bus controller default setting: 0 | 1 A |

Multiplier for generator mains

Name:

ConfigOutput06

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

The value 100 corresponds to a multiplication factor of 1 (measured value not changed).

| Data type | Value | Information | Resolution |
|-----------|------------|---|------------|
| UINT | 1 to 65535 | Corresponds to 0.01 to 655.35. Bus controller default setting: 0 | 0.01 |

Multiplier for current transformer

Name:

ConfigOutput09

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

| Data type | Value | Information | Resolution |
|-----------|------------|---|------------|
| UINT | 1 to 65535 | Corresponds to 1 to 65535. Bus controller default setting: 0 | 1 |

Overvoltage limit of generator mains (U_{max})

Name:

ConfigOutput16

If the value of one of the linked generator voltages exceeds the value set here, then the "Overvoltage" error message (register "Error registers" on page 2840) is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of U_{NomGen} . Bus controller default setting: 0 | 0.1% |

Nominal voltage range of generator mains

Name:

ConfigOutput20

Can be toggled between 100 and 400 V.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 1 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|--|
| 0 | Voltage | 0 | 100 V |
| | | 1 | 400 V (bus controller default setting) |
| 1 - 7 | Reserved | - | |

Nominal current range of the generator mains

Name:

ConfigOutput24

Can be toggled between 1 and 5 A.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 1 |

Bit structure:

| Bit | Description | Value | Information |
|-------|---------------|-------|--------------------------------------|
| 0 | Current range | 0 | 1 A |
| | | 1 | 5 A (bus controller default setting) |
| 1 - 7 | Reserved | - | |

Aron circuit

Name:

ConfigOutput25

Switch to power measurement principle of Aron circuit.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|-------|--------------|-------|--|
| 0 | Aron circuit | 0 | Disabled: Three-phase power system with neutral conductor (bus controller default setting) |
| | | 1 | Enabled: Three-phase supply without neutral line |
| 1 - 7 | Reserved | - | |

Undervoltage limit of generator mains (U_{min})

Name:

ConfigOutput27

If the value of one of the linked generator voltages falls below the value set here, then the "Undervoltage" error message (register "[Error register](#)" on page 2840) is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of U_{NomGen} . Bus controller default setting: 0 | 0.1% |

Low-pass filter for total power ratings

Name:

ConfigOutput41

Parameter for the response time of the low-pass filter of the total power values P, Q and S. The maximum total power values are recorded independently of this without being filtered.

This parameter is used as a delay element so that current or voltage fluctuations have less effect on how the calculated power values are represented. The damping behavior of the low-pass filter acts in accordance with the configurable time constant of a decaying e-function.

| Data type | Value | Information | Resolution |
|-----------|----------|--|------------|
| UINT | 0 to 300 | Corresponds to 0 to 300 ms. Bus controller default setting: 0 | 1 ms |

9.26.2.18.4.2 Generator monitoring**Nominal frequency (f_{Nom})**

Name:

ConfigOutput10

This is needed for converting the percentages based on this nominal value into physical units.

| Data type | Value | Information | Resolution |
|-----------|------------|--|------------|
| UINT | 480 to 620 | Corresponds to 48 to 62 Hz. Bus controller default setting: 0 | 0.1 Hz |

Response time for generator overvoltage (U_{max})

Name:

ConfigOutput26

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

| Data type | Value | Information | Resolution |
|-----------|----------|--|------------|
| UINT | 5 to 100 | Corresponds to 0.5 to 10 s; Bus controller default setting: 0 | 0.1 s |

Response time for generator undervoltage (U_{min})

Name:

ConfigOutput28

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--|------------|
| UINT | 5 to 100 | Corresponds to 0.5 to 10 s; Bus controller default setting: 0 | 0.1 s |

Generator over-frequency (f_{max})

Name:

ConfigOutput29

If the value of the generator frequency exceeds the percentage of the nominal frequency set here, then the error message "Overfrequency" is indicated (register "[Error register](#)" on page 2840) and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} . Bus controller default setting: 0 | 0.1% |

Response time for generator over-frequency (f_{max})

Name:

ConfigOutput30

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

| Data type | Value | Information | Resolution |
|-----------|----------|--|------------|
| UINT | 5 to 100 | For 0.5 for 10 s. Bus controller default setting: 0 | 0.1 s |

Generator under-frequency (f_{min})

Name:

ConfigOutput31

If the value of the generator frequency falls below the percentage of the nominal frequency set here, then the error message "Underfrequency" is indicated (register "Error register" on page 2840) and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} . Bus controller default setting: 0 | 0.1% |

Response time for generator under-frequency (f_{min})

Name:

ConfigOutput32

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

| Data type | Value | Information | Resolution |
|-----------|----------|---|------------|
| UINT | 5 to 100 | For 0.5 to 10 s. Bus controller default setting: 0 | 0.1 s |

Generator voltage asymmetry (U_{as})

Name:

ConfigOutput33

The trigger value, which is adjustable by percentage, is always based on the respective average voltage of the linked generator voltages. If the value of the voltage difference exceeds or falls below the value set here, then the "Voltage asymmetry" error message is indicated (register "Error register" on page 2840) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|----------|---|------------|
| UINT | 0 to 300 | For 0 to 30% of $U_{3average}$. Bus controller default setting: 0 | 0.1% |

Response time for generator voltage asymmetry (U_{as})

Name:

ConfigOutput34

This error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

| Data type | Value | Information | Resolution |
|-----------|----------|---|------------|
| UINT | 5 to 100 | For 0.5 to 10 s. Bus controller default setting: 0 | 0.1 s |

Load time constant for current asymmetry

Name:

ConfigOutput35

The dependent delayed unbalanced load monitoring function continually monitors the AC currents coming from the main current converters and continually calculates the present unbalanced load current. This is compared with the threshold value, which is calculated using the load time constants. If this threshold value is exceeded, the error message "Current asymmetry" is indicated (register "Error register" on page 2840) and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|------------|---|------------|
| UINT | 1 to 65535 | For 0.1 to 6553.5 s. Bus controller default setting: 0 | 0.1 s |

Dependent delayed unbalanced load monitoring

Unbalanced load monitoring protects against unbalanced load in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An unbalanced load can be caused by uneven current distribution in the mains due to unbalanced load, asymmetrical short circuits, line interruptions or switching operations. Unbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An unbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an unbalanced load occurs, the characteristics that trigger unbalanced load protection should be adapted to the thermal characteristics of the generator. Unbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

When unbalanced load protection is tripped can be calculated using the following formula:

| Operating mode | Formula |
|----------------------|--|
| Short-term operation | $t = \frac{K1}{\frac{I_2}{I_{Nom}} - 0.08^2}$ |
| Continuous operation | $\frac{I_2}{I_{Nom}} \leq 0.08 \rightarrow t = \infty$ |
| Key | |
| t | Calculated tripping time |
| K1 | Valid load time constant for the generator [s] |
| I ₂ | Calculated inverse current / unbalanced load current [A] |
| I _{Nom} | Nominal current for the generator [A] |

To calculate the tripping time instant, the scan duration of the measurement system (i.e. 20 ms for 50 Hz voltage) is divided by the calculated trigger time, and the results are continually added up. With short-term operation, the value of the summands increases; with continuous operation, it decreases. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

Information:

The boundary between continuous operation and short-term operation is always 0.08 for calculations.

When the generator is at a standstill, the summand is neither reset nor is its value reduced.

Maximum limit of neutral conductor current

Name:

ConfigOutput36

Configurable limit for the neutral conductor current. If the value is exceeded, then the error message "Maximum neutral conductor current" is indicated (register "Error register" on page 2840) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 1000 | For 0 to 100% of I _{Nom} . Bus controller default setting: 0 | 0.1% |

Response time for neutral conductor current monitor

Name:

ConfigOutput37

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

| Data type | Value | Information | Resolution |
|-----------|----------|---|------------|
| UINT | 5 to 100 | For 0.5 to 10 s. Bus controller default setting: 0 | 0.1 s |

Short circuit current

Name:

ConfigOutput38

If the value of the generator current exceeds the percentage based on the converter's nominal current set here, then the error message "Short circuit current" is indicated (register "[Error register](#)" on page 2840) and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|--------------|---|------------|
| UINT | 1000 to 5000 | For 100 to 500% of I_{Nom} . Bus controller default setting: 0 | 0.1% |

Response time for short circuit current

Name:

ConfigOutput39

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

| Data type | Value | Information | Resolution |
|-----------|---------|---|------------|
| UINT | 4 to 30 | For 0.04 to 0.3 s. Bus controller default setting: 0 | 0.01 s |

Rating-dependent overcurrent

Name:

ConfigOutput42

The response value percentage is based on the nominal current of the generator. If the response value is exceeded, then the error message "Rating-dependent overcurrent" is indicated (register "[Error register](#)" on page 2840) and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|--------------|---|------------|
| UINT | 1000 to 2000 | For 100 to 200% of I_{Nom} . Bus controller default setting: 0 | 0.1% |

Rating-dependent overcurrent monitoring

A generator that is operated at its nominal current I_{Nom} normally reaches about half of its maximum thermal load. Operating it above the rated current I_{Nom} result in additional warming, which is permitted until the maximum temperature is reached. The highest permissible continuous temperature is determined by the class of the insulation material used in the generator.

Based on the settings and the current measurement, the device forms an internal model based on an I^2t characteristic curve of the generator temperature. This allows the heat capacity of the generator to be completely utilized for short overloads while at the same time providing full protection. The configurable parameters for determining the machine model include the nominal current I_{Nom} of the generator and the time multiplier.

Integration coefficient for rating-dependent overcurrent (iths)

Name:

ConfigOutput43

To calculate the tripping time instant, the sampling duration of the measurement system is divided by the calculated trigger time (t). The results are continually added up. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

| Data type | Value | Information | Resolution |
|-----------|---------|--|------------|
| UINT | 1 to 20 | For 0.1 to 2. Bus controller default setting: 1 | 0.1 |

For a constant overcurrent, the trigger characteristic curve can be calculated based on the following formula:

$$t = \frac{0.14}{\left(\frac{I}{I_N}\right)^{0.02} - 1} * iths$$

Key:

| | |
|-------|--|
| t | Tripping time [s] |
| I | The highest value of the 3 phase currents [A] |
| I_N | Rating-dependent overcurrent [A] (0.5 to 2 * I_{Nom}) |
| iths | Integration coefficient (0.1 to 2) |

The monitor function can be reset by restarting the module or by falling below the overcurrent value so that the results of the continuous addition decrease according to the formula.

Trigger characteristic curve in accordance with IEC 255-4 (normal, inverse)

The monitor function can be reset by restarting the module or by falling below the overcurrent value so that the results of the continuous addition decrease according to the formula.

Capacitive reactive power

Name:

ConfigOutput44

The capacitive reactive power for the generator is monitored to determine if it falls below the defined response value. In this way, monitoring the capacitive reactive power can be used to detect exciter failure. If the response value is fallen below, then the error message "Capacitive reactive power" is indicated (register "Error register" on page 2840) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

| Data type | Value | Information | Resolution |
|-----------|-----------------|--|------------|
| INT | -32768 to 32767 | For -32768 to 32767 kvar. Bus controller default setting: 0 | 1 kvar |

Response time for reactive power monitoring

Name:

ConfigOutput45

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

| Data type | Value | Information | Resolution |
|-----------|----------|---|------------|
| UINT | 5 to 100 | For 0.5 to 10 s. Bus controller default setting: 0 | 0.1 s |

DO1 function

Name:

ConfigOutput57

This digital output can be set after the defined response time has elapsed depending on the assignment of the generator mains' monitoring variables (X3).

The monitoring variables can be assigned to this input either individually or with additional monitoring variables using an OR connective. This makes it possible to set the relay when there are multiple monitoring variables.

The following monitoring functions can be assigned to the monitoring relay using this register:

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|---------|---|-------|---|
| 0 | Overvoltage (of a phase) | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 1 | Undervoltage (or a phase) | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 2 | Overfrequency | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 3 | Underfrequency | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 4 | Voltage asymmetry | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 5 | Current asymmetry (unbalanced load) | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 6 | Neutral conductor current, maximum | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 7 | Short circuit current | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 8 | Rating-dependent overcurrent | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 9 | Capacitive reactive power (exciter failure) | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 10 | Ready | 0 | Do not assign function (bus controller default setting) |
| | | 1 | Assign function |
| 11 - 15 | Reserved | 0 | |

Information:

The minimum pulse duration when addressing a monitoring function on the error bit via X2X as well as on the relay is 500 ms.

9.26.2.18.4.3 Busbar**Busbar nominal voltage (U_{NomBus})**

Name:

ConfigOutput03

This is needed for converting the percentages based on this nominal value into physical units.

| Data type | Value | Information | Resolution |
|-----------|-------------|---|------------|
| UINT | 70 to 65000 | For 70 to 65000 V. Bus controller default setting: 0 | 1 V |

Multiplier for busbar

Name:

ConfigOutput05

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 thus means a multiplier factor of 1 (measured value not changed).

| Data type | Value | Information | Resolution |
|-----------|------------|--|------------|
| UINT | 1 to 65535 | For 0.01 to 655.35. Bus controller default setting: 0 | 0.01 |

Nominal voltage range of busbar

Name:

ConfigOutput21

Can be toggled between 100 and 400 V.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 1 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|--|
| 0 | Voltage | 0 | 100 V |
| | | 1 | 400 V (bus controller default setting) |
| 1 - 7 | Reserved | - | |

Minimum busbar voltage (U_{Bmin})

Name:

ConfigOutput40

Name:

ConfigOutput40

ConfigOutput40Read

Configurable threshold for zero voltage monitoring of the busbar based on its nominal voltage. DO3 is set if the value falls below the configured threshold.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 1000 | For 0 to 100% of U_{NomBus} . Bus controller default setting: 0 | 0.1% |

9.26.2.18.4.4 Synchronization

Synchronization mode

Name:

ConfigOutput

ConfigOutput17 to ConfigOutput19

If multiple mode bits are set at the same time, then no mode will be selected (type BOOL).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------|-------|----------------------|
| 0 | ConfigOutput17 | 0 | Sync mode ≠ Slip |
| | | 1 | Sync mode = Slip |
| 1 | ConfigOutput18 | 0 | Sync mode ≠ Check |
| | | 1 | Sync mode = Check |
| 2 | ConfigOutput19 | 0 | Sync mode ≠ Dead bus |
| | | 1 | Sync Mode = Dead bus |
| 3 - 7 | Reserved | - | |

Nominal voltage of synchronization mains (U_{NomSyn})

Name:

ConfigOutput01

This is needed for converting the percentages based on this nominal value into physical units.

| Data type | Value | Information | Resolution |
|-----------|-------------|---|------------|
| UINT | 70 to 65000 | For 70 to 65000 V. Bus controller default setting: 0 | 1 V |

Multiplier for synchronization mains

Name:

ConfigOutput07 (mains 1)

ConfigOutput08 (mains 2)

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 means a multiplier factor of 1 (measured value not changed).

| Data type | Value | Information | Resolution |
|-----------|------------|--|------------|
| UINT | 1 to 65535 | For 0.01 to 655.35. Bus controller default setting: 0 | 0.01 |

Max. differential frequency (df_{max})

Name:

ConfigOutput11

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded. This value specifies the upper frequency (positive value corresponds to positive slip → generator frequency is greater than the busbar frequency when synchronizing).

| Data type | Value | Information | Resolution |
|-----------|---------|---|------------|
| UINT | 2 to 49 | For 0.02 to 0.49 Hz. Bus controller default setting: 0 | 0.01 Hz |

Min. differential frequency (df_{min})

Name:

ConfigOutput12

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded in the negative direction. This value specifies the lower frequency (negative value corresponds to negative slip → generator frequency is less than the busbar frequency when synchronizing).

| Data type | Value | Information | Resolution |
|-----------|----------|---|------------|
| INT | -49 to 0 | For -0.49 to 0 Hz. Bus controller default setting: 0 | 0.01 Hz |

Max. differential voltage (dU_{max})

Name:

ConfigOutput13

A switch-on command on DO4 is only output if this configured differential voltage percentage based on the synchronization mains' nominal voltage is not exceeded.

| Data type | Value | Information | Resolution |
|-----------|----------|---|------------|
| UINT | 1 to 300 | For 0.1 to 30% of U_{NomSyn} . Bus controller default setting: 0 | 0.1% |

Max. permitted differential angle (ϕ_{Max})

Name:

ConfigOutput14

A switch-on command on DO4 is only output if the configured differential angle between the two synchronization mains is not exceeded.

| Data type | Value | Information | Resolution |
|-----------|----------|--|------------|
| UINT | 1 to 600 | For 0.1 to 60°. Bus controller default setting: 0 | 0.1° |

Phase rotation of sync mains 1 ($d\alpha$)

Name:

ConfigOutput15

This parameter is used for correcting any phase shifting from upstream transformer vector groups before reaching the mains being synchronized.

This parameter specifies how many degrees the synchronization mains lags behind the mains being synchronized.

| Data type | Value | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 3600 | For 0 to 360°. Bus controller default setting: 0 | 0.1° |

Nominal voltage range of synchronization mains

Name:

ConfigOutput22 (mains 1)

ConfigOutput23 (mains 2)

Can be toggled between 100 and 400 V.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| USINT | See the bit structure. | 1 |

Bit structure:

| Bit | Description | Value | Information |
|-------|-------------|-------|--|
| 0 | Voltage | 0 | 100 V |
| | | 1 | 400 V (bus controller default setting) |
| 1 - 7 | Reserved | - | |

Pulse duration of the turn-on delay

Name:

ConfigOutput47

The duration of the switch-on pulse can be adjusted for the following switching units. The time set here is valid for the switch-on pulse for DO4.

| Data type | Value | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 40 to 500 | For 0.04 to 0.5 s. Bus controller default setting: 0 | 0.001 s |

Switching response time of the power switch

Name:

ConfigOutput48

The actuation time of the generator power switch corresponds to the lead time of the switch-on command. The switch-on command is executed before the point of synchronization according to the amount of time defined here.

| Data type | Value | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 40 to 300 | For 0.04 to 0.3 s. Bus controller default setting: 0 | 0.001 s |

Synchronization configuration

Name:

ConfigOutput56

Parameter for configuring which mains or voltages should be synchronized with each other.

This configuration makes it possible to synchronize the AC mains on terminal X4 either with terminal X3, X5 or X6. In each case, synchronization mains 1 (X4) is the network to which synchronization takes place.

| Data type | Values | Bus controller default setting |
|-----------|------------------------|--------------------------------|
| UINT | See the bit structure. | 0 |

Bit structure:

| Bit | Description | Value | Information |
|--------|-----------------|-------|---|
| 0 - 1 | Synchronization | 00 | X4 - X6: Synchronization network 1 - Synchronization network 2 (bus controller default setting) |
| | | 01 | X4 - X5: Synchronization mains 1 - Busbar |
| | | 10 | X4 - X3: Synchronization mains 1 - Generator |
| | | 11 | Reserved |
| 2 - 15 | Reserved | - | |

Dead bus voltage

Name:

ConfigOutput58

Configurable threshold for dead bus synchronization based on the nominal voltage of the busbar.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 1000 | For 0 to 100% of U_{NomBus} . Bus controller default setting: 0 | 0.1% |

9.26.2.18.4.5 Maximum value buffer and power meter**Pulse value of energy meter output**

Name:

ConfigOutput46

Output DO2 outputs pulses that occur at a frequency proportional to the measured energy. The frequency of the pulses can be specified. The length of the pulse is 400 ms. The frequency at which the pulses occur should be set so that the duration between two pulses does not exceed 400 ms at the highest possible power. The pulse output's internal meter starts at 0 kWh after a restart. This register has no effect on the "[ConfigOutput54](#)" on page 2838 and "[ConfigOutput55](#)" on page 2838 registers.

| Data type | Value | Information | Resolution |
|-----------|------------|--|-------------|
| UINT | 0 to 65535 | For 0 to 65535 kWh/pulse. Bus controller default setting: 0 | 1 kWh/pulse |

Maximum value buffer and meter buffer

These registers are used for nonvolatile storage of the maximum value and meter level values. After restarting, the stored maximum values and meter states are loaded back into their registers and the module's internal work meter is reset. It is possible to reset or write to the stored maximum values and meter states using an acyclic register.

The maximum values are recorded by the effective measured values before reaching the configurable filter. The maximum values can be read or written to as acyclic registers.

Maximum phase current

Name:

Reading: ConfigOutput49 (generator I1)

Reading: ConfigOutput50 (generator I2)

Reading: ConfigOutput51 (generator I3)

Reset: ConfigOutput60 (generator I1)

Reset: ConfigOutput61 (generator I2)

| | | 1 | Phase 1 sync mains 1 failure |
| 15 | StatusInput15 | 0 | Phase 1 sync mains 2 OK |
| | | 1 | Phase 1 sync mains 2 failure |
| 15 | Reserved | - | |

StatusInput11

The error message "Not ready" is triggered if the X20 I/O supply drops below 18 VDC.

StatusInput

(StatusInput12 to StatusInput 14)

Phase failure is detected if phase 1 of the respective terminal fails.

If this error occurs, it will mean losses in measurement precision.

9.26.2.18.5.2 Generator mains measured values

Phase currents of the generator

Name:

AnalogInput01 (I1)

AnalogInput02 (I2)

AnalogInput03 (I3)

Phase currents of the generator

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Current average of generator I1, I2, I3

Name:

AnalogInput04

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Neutral conductor current of generator I_n

Name:

AnalogInput05

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Dynamic current average of generator (I_{m_dyn})

Name:

AnalogInput06

Describes the change to the current average.

The dynamic average is the amount of change (I_{m_diff}) of the current average (sampling time: 10 ms).

This value decays in an e-function.

$$I_{m_diff} > I_{m_dyn} \rightarrow I_{m_dyn} = I_{m_diff}$$

$$I_{m_diff} \leq I_{m_dyn} \rightarrow I_{m_dyn} = I_{m_dyn} * 0.98$$

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 1 A |

Line-to-line voltages of the generator

Name:

AnalogInput07 (UG12)

AnalogInput08 (UG23)

AnalogInput09 (UG31)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Phase voltages of the generator

Name:

AnalogInput10 (UG 1)

AnalogInput11 (UG 2)

AnalogInput12 (UG 3)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Generator power: Total active power P

Name:

AnalogInput19

Filtered generator power values:

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 kW |

Generator power: Total reactive power Q

Name:

AnalogInput20

Filtered generator power values:

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|

Generator power: Total apparent power S

Name:

AnalogInput21

Filtered generator power values:

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 kVA |

Voltage average of the generator

Name:

AnalogInput22

Voltage average of the generator UG12, UG23, UG31 (U~3 average)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Power factor of generator/cos ϕ

Name:

AnalogInput23

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 0.001 |

Frequency of the generator mains

Name:

AnalogInput24

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

9.26.2.18.5.3 Busbar measured values**Line-to-line voltages of the busbar**

Name:

AnalogInput13 (UB12)

AnalogInput14 (UB23)

AnalogInput15 (UB31)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Phase voltages of the busbar

Name:

AnalogInput16 (UB1)

AnalogInput17 (UB2)

AnalogInput18 (UB3)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

9.26.2.18.5.4 Synchronization mains measured values**Line-to-line voltages**

Name:

AnalogInput25 (sync mains 1 US1)

AnalogInput26 (sync mains 2 US2)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Frequencies

Name:

AnalogInput27 (sync mains 1)

AnalogInput28 (sync mains 2)

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

Differential angle between synchronization mains

Name:

AnalogInput29

Angular difference between the mains being synchronized

Specifies how many degrees the sync mains are ahead of the mains being synchronized.

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 0.1° |

Differential voltage between synchronization mains

Name:

AnalogInput30

Voltage difference between the mains being synchronized

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

9.26.2.18.6 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| ≥ 250 μs |

9.26.2.18.7 Minimum I/O update time

The minimum I/O update time for the analog inputs depends on the respective period duration of the measurement signal frequency.

| Minimum I/O update time | |
|-------------------------|-------|
| At 50 Hz | 20 ms |

9.26.3 X20CM0985-02

Data sheet version: 1.02

9.26.3.1 General information

The module combines a power measurement module with special features in a compact footprint together with a synchronizing unit that meets all requirements.

The measurement unit is suitable for both X: 1 A and X: 5 A current transformers. Overcurrent resistance and the high resolution of the unit of measurement round off its features. For the voltage inputs, the value range can also be configured between 480 VAC and 120 VAC without any loss in converter resolution.

The area of application includes 4-wire AC power systems with a line-to-line voltage up to 480 VAC and 3-wire systems, where L2 can be grounded (V circuit). In addition, the module masters the measuring principle of the Aron circuit.

The resulting measured values range from the pure phase current and line-to-line or phase voltage to active, reactive and apparent power components, mains frequency, power factor and much more. In addition, peak values and energy meters are stored on the module in nonvolatile memory. Depending on the configuration, it is also possible to use a digital output as a pulse encoder for an external energy meter.

The synchronization unit does not just take the phasing and phase voltage into consideration; integrated intelligence also monitors the rate of change and other parameters, allowing them to influence when the synchronization output is switched. It is also possible to monitor a generator using a large number of additional conditions. A total of 4 voltage inputs provide substantial overall flexibility.

Monitoring functions expand the features of the module. Rating-dependent overcurrent monitoring is included, which utilizes the thermal capacity of the motor/generator to allow short overloads while still providing full protection. The dependent, delayed imbalanced load monitoring used to protect three-phase generator and three-phase networks from imbalanced load can be adapted to the characteristics of different generator types using parameters while taking their special thermal time constants into account.

- Energy measurement for 120 to 480 VAC
- Simultaneous measurement of 2 AC power systems plus 2 additional voltages
- For multifunction measurement tasks
- Intelligent power system synchronization unit
- Current values of generator voltage and current
- Monitor functions per current power system guidelines

9.26.3.4 Safety guidelines

General information

Programmable logic controllers, operating/monitoring devices (e.g. industrial PCs, Power Panels, Mobile Panels, etc.) as well as uninterruptible power supplies have all been designed, developed and manufactured by B&R for conventional use or for use with increased safety requirements (safety technology) in industry. They were not designed, developed and manufactured for any use involving serious risks or hazards that could lead to death, injury, serious physical damage or loss of any kind without the implementation of exceptionally stringent safety precautions. In particular, such risks and hazards include the use of these devices to monitor nuclear reactions in nuclear power plants, their use in flight control or flight safety systems as well as in the control of mass transportation systems, medical life support systems or weapons systems.

When using programmable logic controllers or operating/monitoring devices as control systems together with a Soft PLC (e.g. B&R Automation Runtime or comparable product) or Slot PLC (e.g. B&R LS251 comparable product), safety precautions relevant to industrial control systems (e.g. the provision of safety devices such as emergency stop circuits, etc.) must be observed in accordance with applicable national and international regulations. The same applies for all other devices connected to the system, e.g. drives.

All tasks such as the installation, commissioning and servicing of devices are only permitted to be carried out by qualified personnel. Qualified personnel are those familiar with the transport, mounting, installation, commissioning and operation of devices who also have the appropriate qualifications (e.g. IEC 60364-1). National accident prevention regulations must be observed.

The safety notices, connection descriptions (type plate and documentation) and limit values listed in the technical data are to be read carefully before installation and commissioning and must be observed.

Intended use

Danger!

Electronic devices are never completely failsafe. If the multi-measurement and synchronization unit fails, the user is responsible for making sure that the motor or generator is brought to a secure state.

Some errors are detected and prevented in the synchronization unit by the system's internal software monitoring. However, when the device is in operation it is always possible for errors, defective components, software errors or configuration mistakes to occur at any time. B&R emphasizes that the multi-measurement and synchronization unit possesses neither a failsafe function nor a redundancy system. For this reason, independent higher-level safety precautions need to be put in place to ensure that personnel and machines are protected.

Grounding the Mounting Rail

For grounding purposes, a good conductive connection between the mounting rail and the metal back wall is required. The mounting rail is to be connected conductively to the back wall. This is achieved by inserting a contact washer with the fastening screw.

Information:

The control cabinet back wall must be connected with GND

9.26.3.5 LED status indicators

For a description of the various operating modes, see "Diagnostic LEDs" on page 3787.

LED status indicators - Left

| Figure | LED | Color | Status | Description |
|---|-------|--------------------------------|----------------------|--|
|  | r | Green | Off | No power to module |
| | | | Single flash | Mode RESET |
| | | | Double flash | Mode BOOT (during firmware update) ¹⁾ |
| | | | Blinking | Mode PREOPERATIONAL |
| | | | On | Mode RUN |
| | e | Red | Off | Module not supplied with power or everything OK |
| | On | | Error or reset state | |
| | e + r | Solid red / Single green flash | Invalid firmware | |
| | 1 - 6 | Orange | | Output state of the corresponding digital output |

1) Depending on the configuration, a firmware update can take up to several minutes.

LED status indicators - Right

| Figure | LED ¹⁾ | Terminal | Color | Status | Description |
|---|-------------------|----------|-------|--------|----------------------------|
|  | 1 | X3 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 2 | X4 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 3 | X5 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 4 | X6 | Green | On | Measurement range: 120 VAC |
| | | | Red | On | Measurement range: 480 VAC |
| | 5 | X2 | Green | On | Measurement range: 1 A |
| | | | Red | On | Measurement range: 5 A |

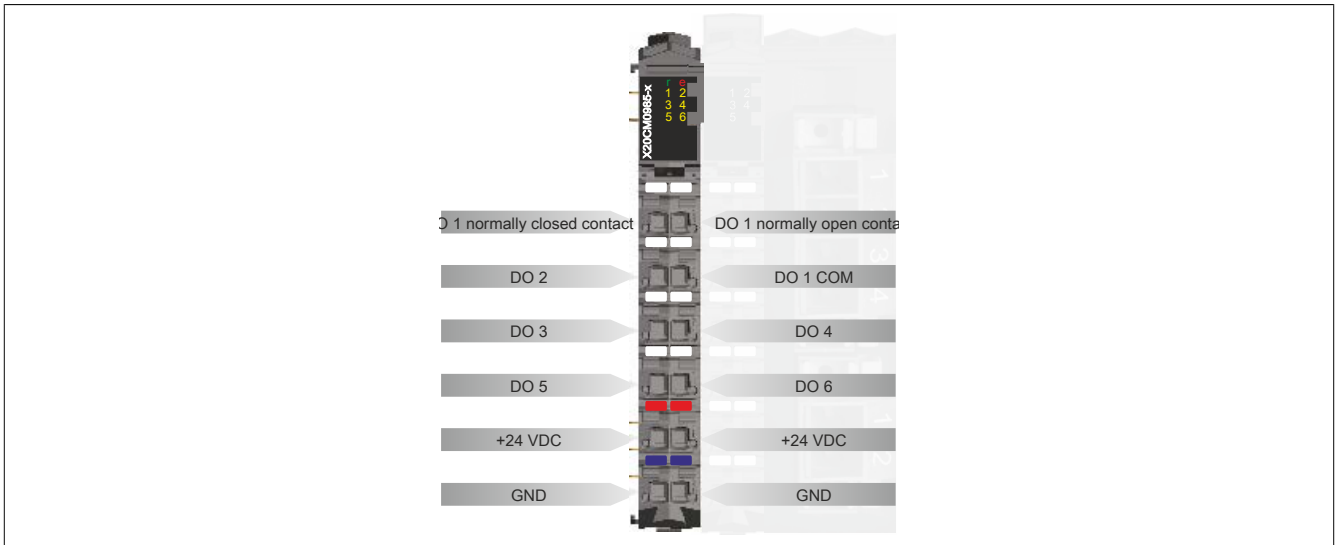

1) LEDs 1 - 5 are green/red dual LEDs.

9.26.3.6 Connection elements

9.26.3.7 Digital outputs X1

Terminals X1 and X2 can be keyed differently to prevent unintentional incorrect connection on the module.

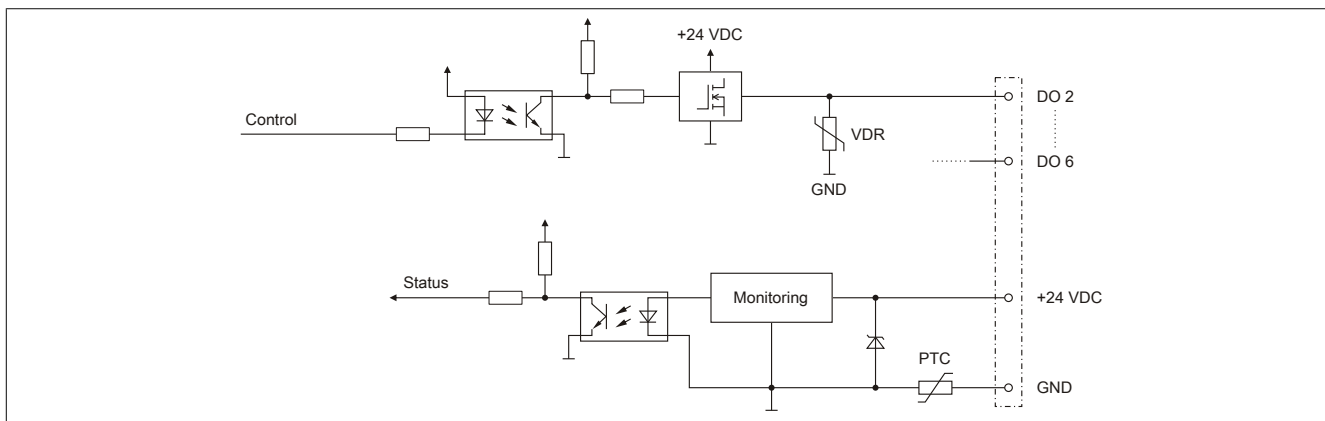

Function description of the digital outputs

| Digital output | Description |
|----------------|--|
| DO1 | <p>This output is designed as a changeover contact switch and serves either as a digital output or monitoring relay (see register "ConfigOutput24" on page 2876) for monitoring the following measured values of the generator mains:</p> <ul style="list-style-type: none"> • Overvoltage and undervoltage • Overfrequency and underfrequency • Voltage asymmetry • Current asymmetry • Calculated neutral conductor current (maximum) • Short circuit current • Rating-dependent overcurrent • Limit value of the capacitive reactive power (exciter failure) • Generator overload • Generator feedback • Inductive reactive power reference (Q-U protection) |
| DO2 | DO2 serves as a meter output. The generated pulses can be recorded by an external energy meter (kWh). |
| DO3 | This output is set when there is no voltage on the bus bar (below the lower limit of the defined parameter). 3-phase monitoring takes place for the bus bar voltage. |
| DO4 | DO4 serves as a synchronization pulse. The power switch is activated by setting this output. The output is deactivated after the configured time has elapsed (exception:Synchro check operating mode). |
| DO5 | <p>This output can be configured either as a digital output or monitoring output (see register "ConfigOutput24" on page 2876). The monitoring function is only available with the "3-phase mains" configuration. When configured as monitoring output, the user can choose between monitoring the following mains measurement values:</p> <ul style="list-style-type: none"> • Overvoltage and undervoltage • Overfrequency and underfrequency • Voltage asymmetry • Phase shift • Frequency change <p>The monitoring status can be output either normally or inverted. This can be defined using the "DigitalOutput" on page 2910 register. This setting is then disabled when shutting off, resetting, restarting, etc.</p> |
| DO6 | <p>Can be configured as a digital output or synchronization output (see register "ConfigOutput24" on page 2876).</p> <p>When configured as a synchronization output: DO6 serves as the synchronization pulse. The power switch is activated by setting this output. The output is deactivated after the configured time has elapsed (exception:Synchro check operating mode).</p> |

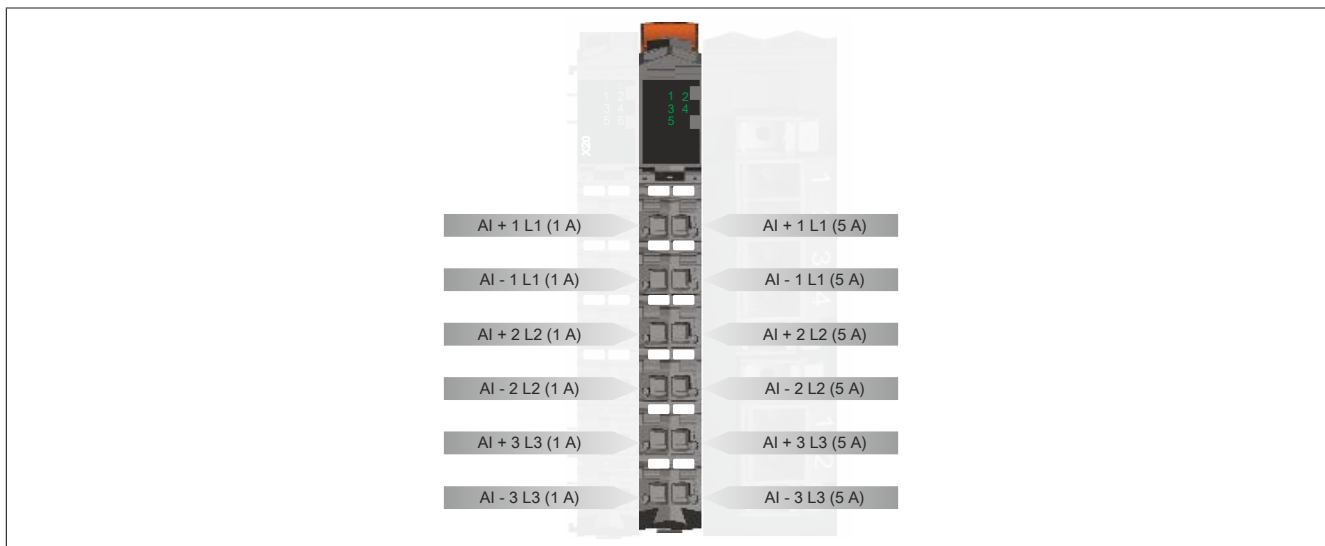

DO1 - Output circuit diagram

DO2 - DO 6 - Output circuit diagram**9.26.3.8 X2 analog current inputs**

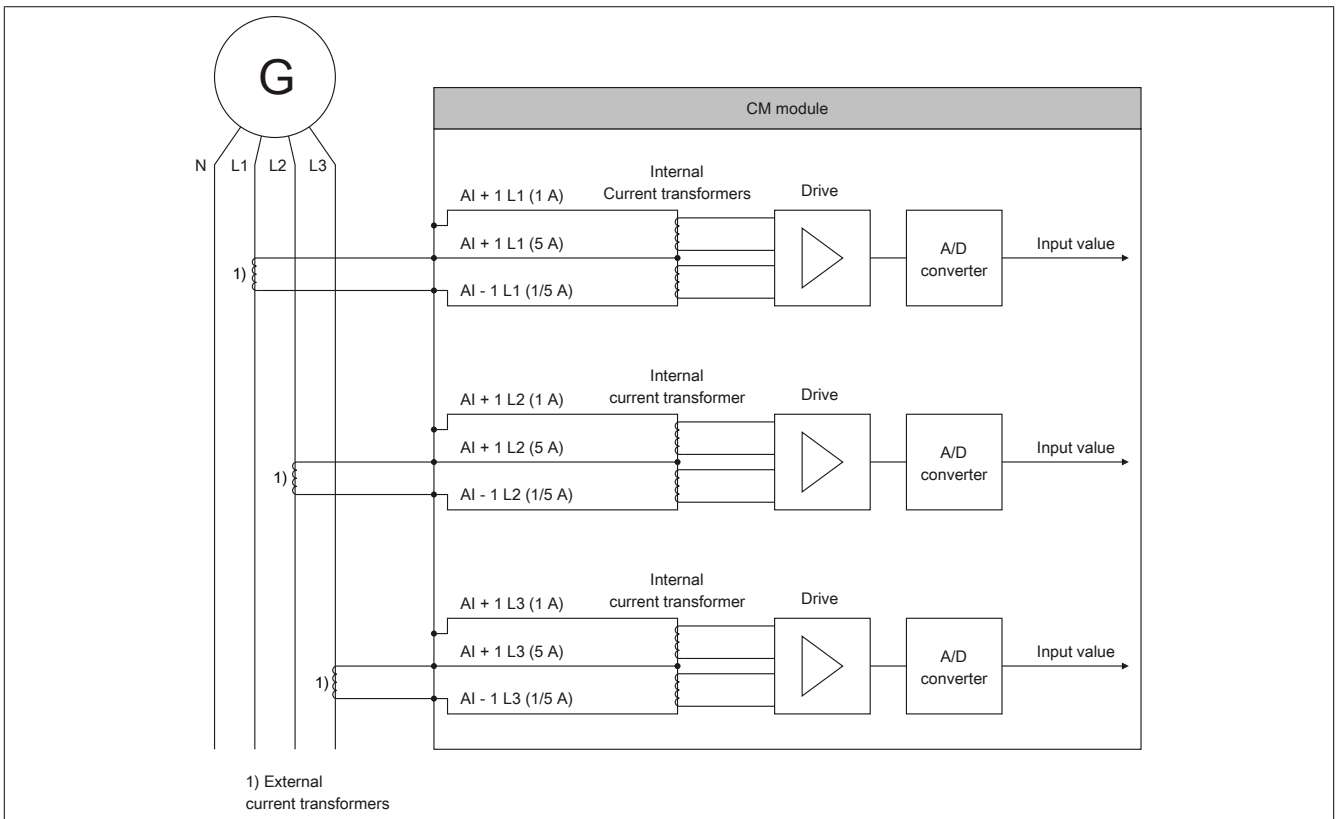

The X2 terminal measures the three phase currents of the generator mains using an externally connected current transformer. The measurement range of the current inputs can be configured as 1 A or 5 A.

Terminals X1 and X2 can be keyed differently to prevent unintentional incorrect connection on the module.

**Danger!****Risk of electric shock!**

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

Input circuit diagram - Analog current inputs

9.26.3.9 X3 and X5 analog voltage inputs

The X3 and X5 terminals are used to measure and monitor the line-to-line and phase voltages of the generator mains and bus bar.

- Terminal X3: Generator mains
- Terminal X5: Bus bar

Terminals X3 and X5 are keyed differently to prevent unintentional incorrect connection on the module. Section ["Releasing the locking clip for terminals X3 - X6" on page 2861](#) describes how to release the terminal locking clip.

9.26.3.10 X4 and X6 analog voltage inputs

Terminals X4 and X6 are keyed differently to prevent unintentional incorrect connection on the module. Section "Releasing the locking clip for terminals X3 - X6" on page 2861 describes how to release the terminal locking clip.

The two terminals are connected differently depending on the selected configuration (see register "ConfigOutput68" on page 2875).

Configuration as Sync-mains 1 / Sync-mains 2

The voltage inputs on the X4 and X6 terminals are used to determine the line-to-line voltages for synchronization between two different mains networks.

- Terminal X4: Synchronization mains network 1
- Terminal X6: Synchronization mains network 2

Configuration as 3-phase mains

The terminals X4 and X6 can be combined to form a 3-phase mains. The X4 and X6 terminals are used to measure and monitor the line-to-line voltages and phase voltages of the power mains.

Input circuit diagram, analog voltage inputs

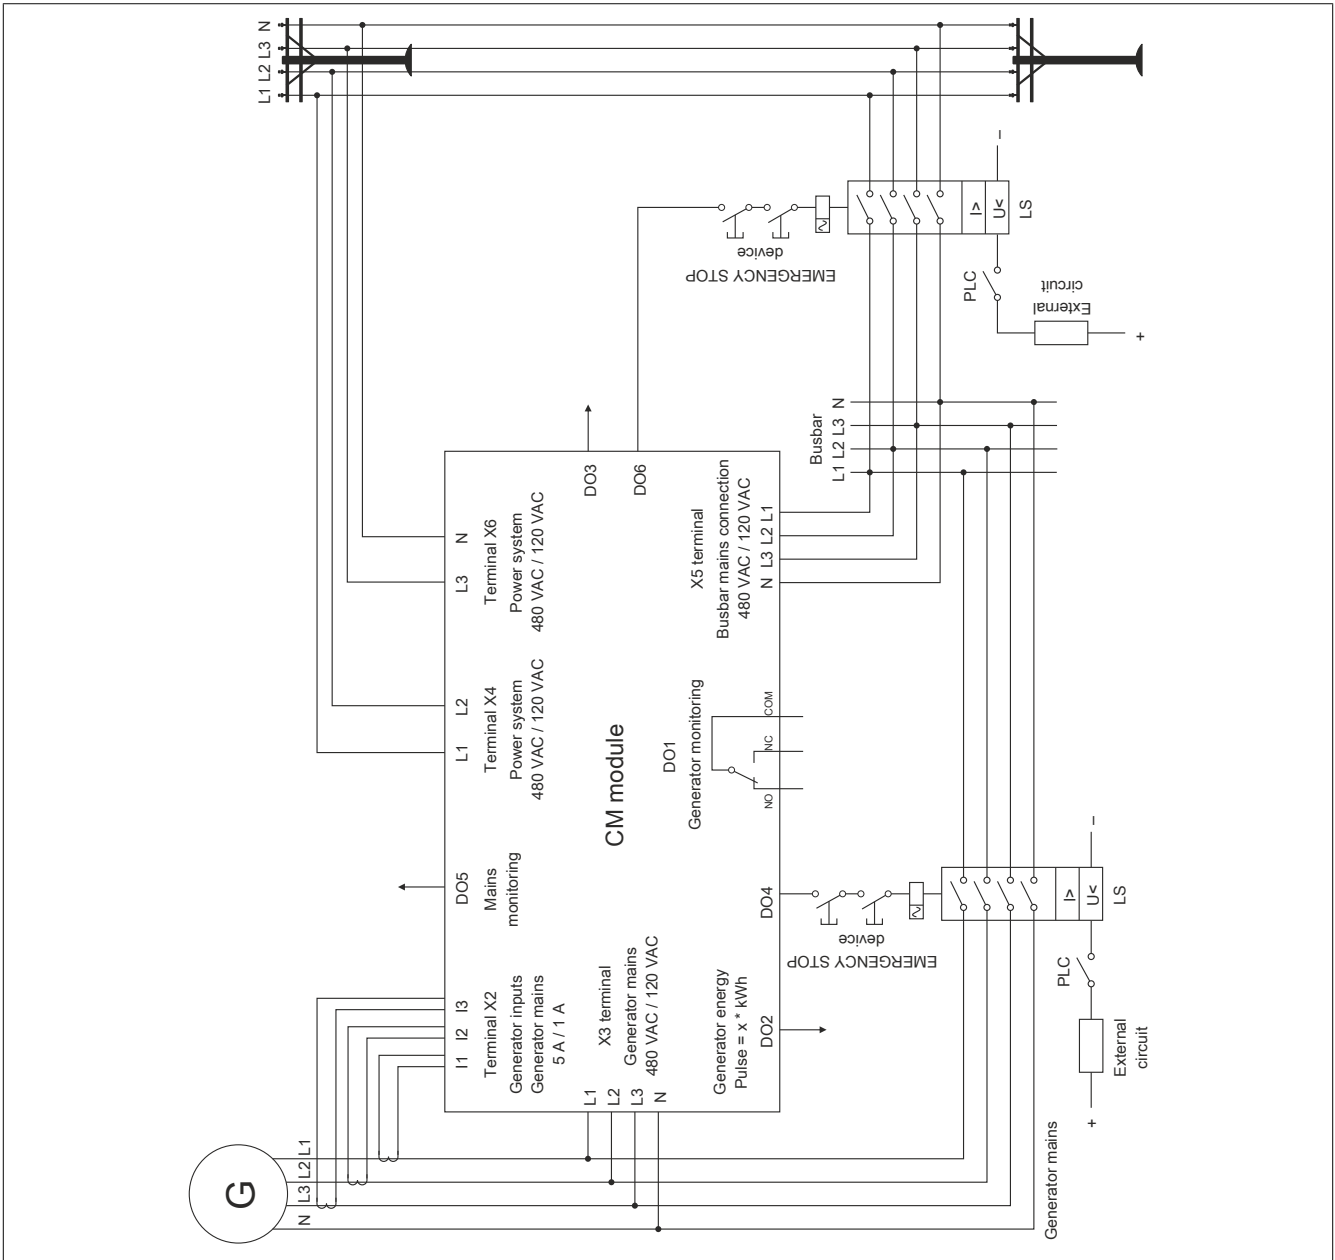

9.26.3.11 Circuit diagram

Example of mains configuration "Sync-mains 1 / Sync-mains 2"

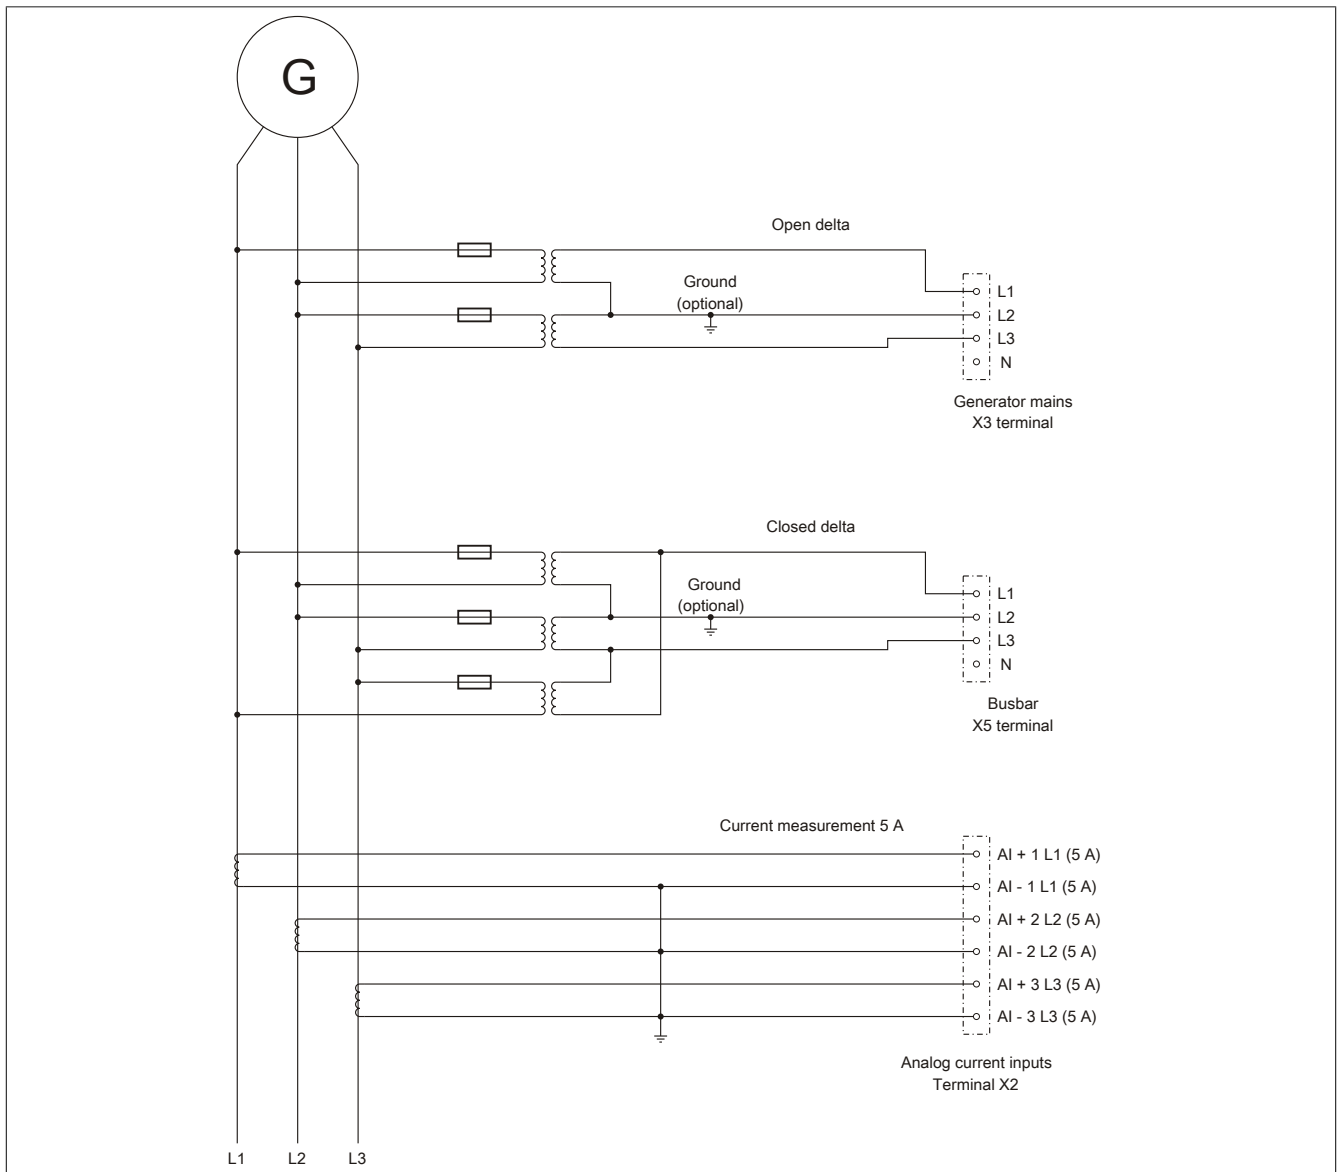

Example of mains configuration "3-phase mains"

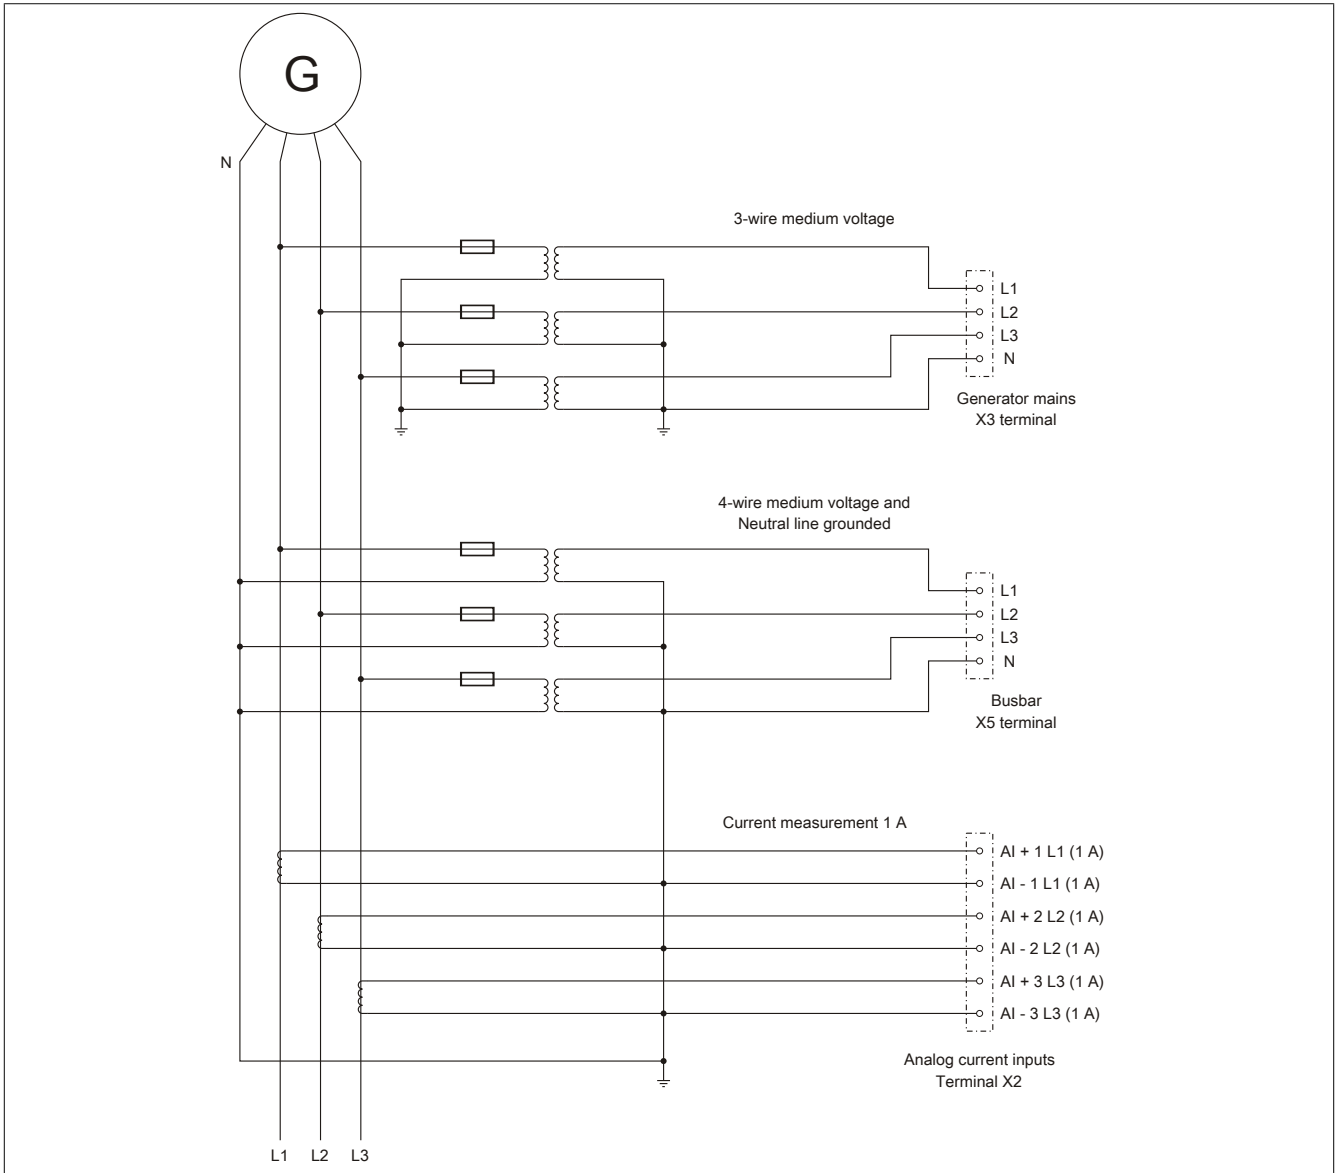

9.26.3.12 Typical connection examples for voltage/current measurement

For power measurement, the X3 terminal must always be used in connection with the X2 terminal! For single-phase measurement, always ensure that current input 1 is used for power measurement if voltage input 1 is being used. Otherwise, accurate power measurement is not possible for this phase!

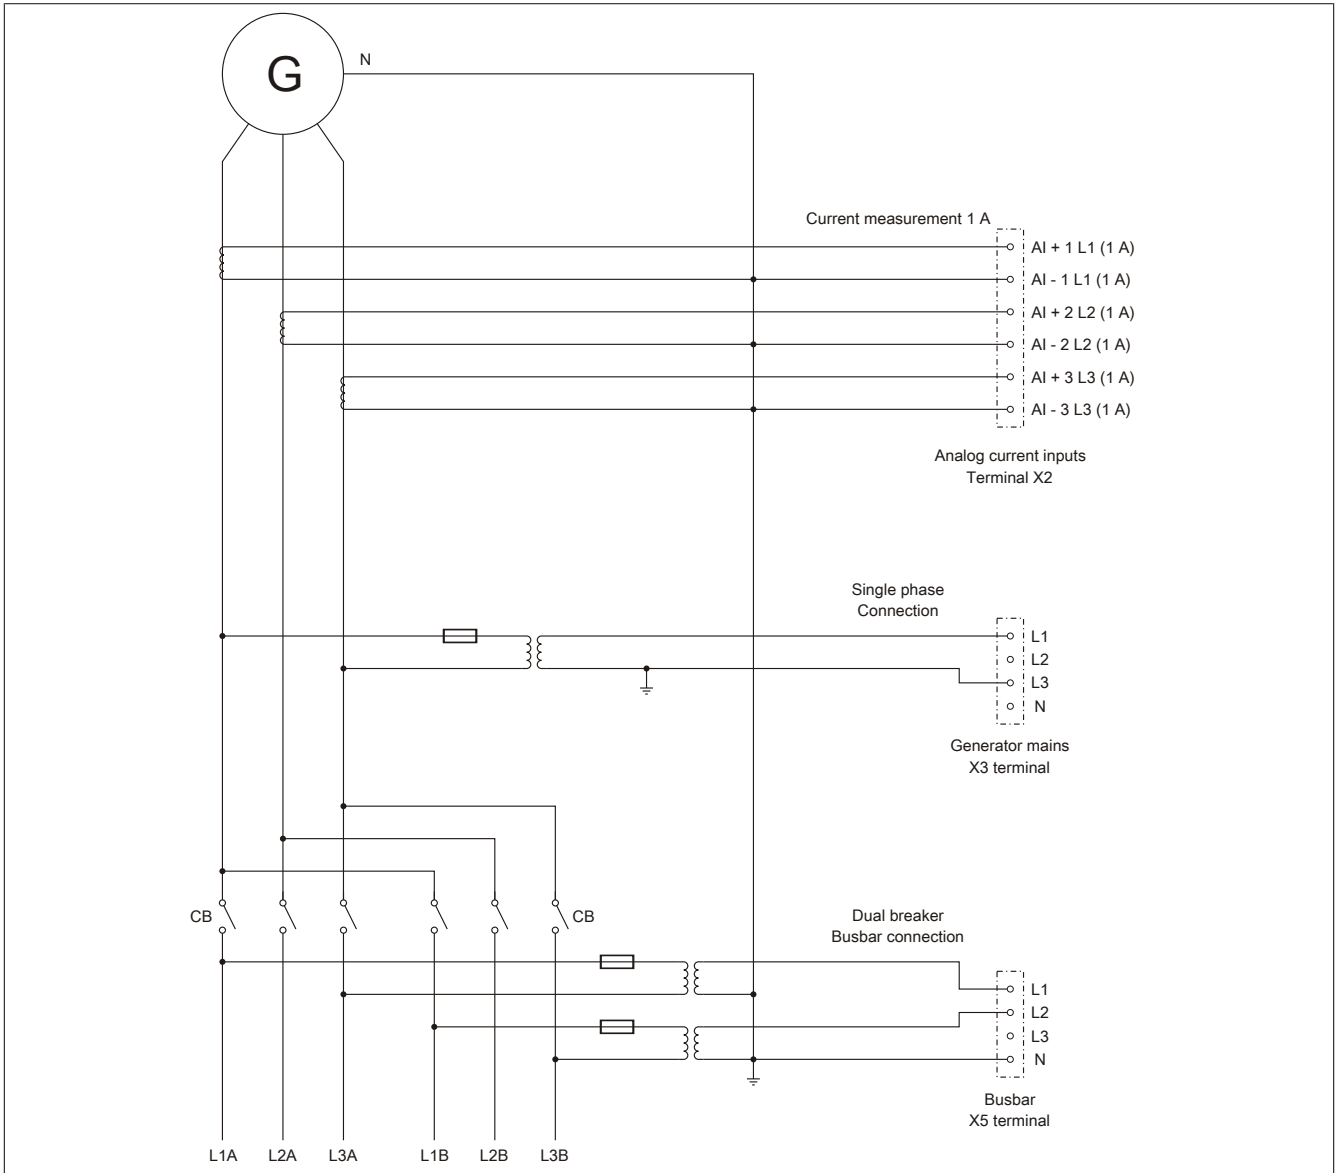

Connection example 1

Connection example 2

Connection example 3

Connection example 4

9.26.3.13 Electrical service life

The electrical service life for the DO1 relay output can be seen in the following diagram.

9.26.3.14 Releasing the locking clip for terminals X3 - X6

Terminals X3 - X6 are equipped with a terminal locking clip. This clip attaches the terminal block securely to the electronic module. This prevents the terminal from accidentally being disconnected.

To release the locking clip, press inwards on the corrugated part of the lever with your fingertip (1) and then slide outwards (2). No additional tools are required for removing the terminal.

Terminals X5 and X6 must be removed first before terminals X3 and X4 can be removed.

9.26.3.15 Synchronization functions

The following three synchronization functions are available on the module:

- "Synchronization with slip" on page 2862
- "Synchro check" on page 2862
- "Switching to voltage-free "dead bus"" on page 2863

Synchronization with slip

The following is valid for synchronization mains 1 and synchronization mains 2:

- $50\% < U < 125\%$ of the nominal voltage U_N
- $80\% < f < 110\%$ of the nominal frequency f_N

The generator voltage is adjusted to the synchronization voltage with regard to amplitude and frequency. Taking into account the configured phase angle ($\Delta\alpha$), a defined transformer vector group and the switching response time, the switch-on command is calculated and transmitted in advance so that the main contacts of the power switch are closed at the point of synchronicity.

Synchronization occurs under the following conditions:

- Synchronization mode "Slip" is set using software.
- The device is ready.
- The phase sequences of the mains networks being synchronized are OK (phase sequence detection).
- The configured limit for voltage difference is not exceeded (ΔU_{\max}).
- The configured limits for frequency difference are not exceeded (Δf_{\max} and Δf_{\min}).
- The configured limit for the phase angle (including vector group transformer $\Delta\alpha$) is not exceeded (j_{\max}).

When the synchronization mode is set to "Slip", synchronization is not activated until the value of the differential angle between the two synchronized mains networks is $>5^\circ$ for at least 100 ms.

In other words, if the phase difference happens to be within $\pm 5^\circ$ at the time of the synchronization request, the synchronization won't be activated unless/until the phase difference is larger for 100 ms.

Resetting the mode "Synchronization with slip" cancels the synchronization.

In order to receive a synchronization pulse, the synchronization window must be entered from any phase direction after the synchronization command has been authorized and all of the synchronization conditions specified above are observed.

The switch is not engaged immediately after reaching the phase window. The switch is only engaged if synchronization is possible at the synchronization point while observing the switch lead time.

With very low frequency differences or equivalent frequencies and in adherence to the conditions described above, synchronization will also take place at a phase angle = 0° .

The synchronization output changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

Synchro check

In this operating mode, the device can be used to check the synchronization. The DO4 output remains set as long as the following conditions are met:

- The "-Check" command is set using software.
- The device is ready.
- The phase sequences of the mains networks being synchronized are OK (phase sequence detection).
- The configured limit for voltage difference is not exceeded (ΔU_{\max}).
- The configured limits for frequency difference are not exceeded (Δf_{\max} and Δf_{\min}).
- The defined limit for the phase angle is not exceeded (ϕ_{\max}).

DO4 stays at High as long as all conditions are met.

Switching to voltage-free "dead bus"

The switch-on command for the power switch is output without synchronization if the following conditions have been met:

- The "Dead Bus" command is set using software.
- The device is ready.
- The bus bar does not have voltage applied: $U_B < U_{BminSync}$ as a percentage of U_{NomBus}

| | |
|--------------------|-------------------------|
| U_B ... | Bus bar phase voltage |
| $U_{BminSync}$... | Dead bus voltage |
| U_{NomBus} ... | Bus bar nominal voltage |

DO4 changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

9.26.3.16 Measurement functions

Timing diagram

Measured parameters for generator mains (X3)

- Phase currents
- Current average
- Dynamic current average
- Neutral current
- Line-to-line voltages
- Phase voltages
- Voltage average
- Total apparent power
- Total reactive power
- Total active power
- Active power factor
- Frequency
- Instantaneous values of the phase voltages
- Instantaneous values of the phase currents

Measured parameters between synchronization mains networks

- Differential angle
- Differential voltage

Rating-dependent overcurrent

Rating-dependent overcurrent monitoring is in accordance with the specifications of IEC 255-8 "Electrical relay; Relay for protecting against thermal overload (overload relay)" and IEC 255-17 "Electrical relay; Relay for protecting against the thermal overload of motors (overload relay for motors).

Dependent delayed imbalanced load monitoring

Dependent delayed imbalanced load monitoring protects against imbalanced loads in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An imbalanced load can be caused by uneven current distribution in the mains due to imbalanced load, asymmetrical short circuits, line interruptions or switching operations. Imbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An imbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an imbalanced load occurs, the characteristics that trigger imbalanced load protection should be adapted to the thermal characteristics of the generator. Imbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

Short circuit current monitoring

If overcurrent or a short circuit occurs and the limit value is exceeded, the error message "Short circuit current" is signaled after the configured time delay has passed.

Voltage asymmetry monitoring

This trigger value, specified as a percentage, is based on the nominal voltage of the generator. If the difference between the three line-to-line voltages of the generator mains exceeds the set limit value, then the error message "Voltage asymmetry" is signaled after the response time has passed. For this to happen, only one of these voltages has to exceed the respective limit value (in either the positive or negative direction).

Bus bar voltage measurement and zero voltage monitoring

3-phase monitoring takes place for the bus bar voltage. The measured values are represented as phase-to-phase and phase-to-neutral values. The DO3 output is set when there is no voltage (below the lower limit of the defined limit bus bar voltage minimum U_{Bmin}) on the bus bar (X5 terminal).

This monitoring can be used to determine which synchronization function should be used.

| Synchronization function | Bus bar voltage measurement |
|---------------------------|---|
| Dead bus | No voltage is being supplied to the bus bar or the value is below the lower limit parameter. Output DO3 is set. |
| Synchronization with slip | The voltage measured on the bus bar is above the defined parameter value. Output DO3 is not set. |

Exciter failure

The reactive power monitoring can be used to protect a generator against operating in the impermissible range. The capacitive reactive power monitor offers protection against under-excitation (exciter failure). If the lower limit is exceeded (in the negative direction), the error message "Capacitive reactive power" is signaled after the configured time delay has passed.

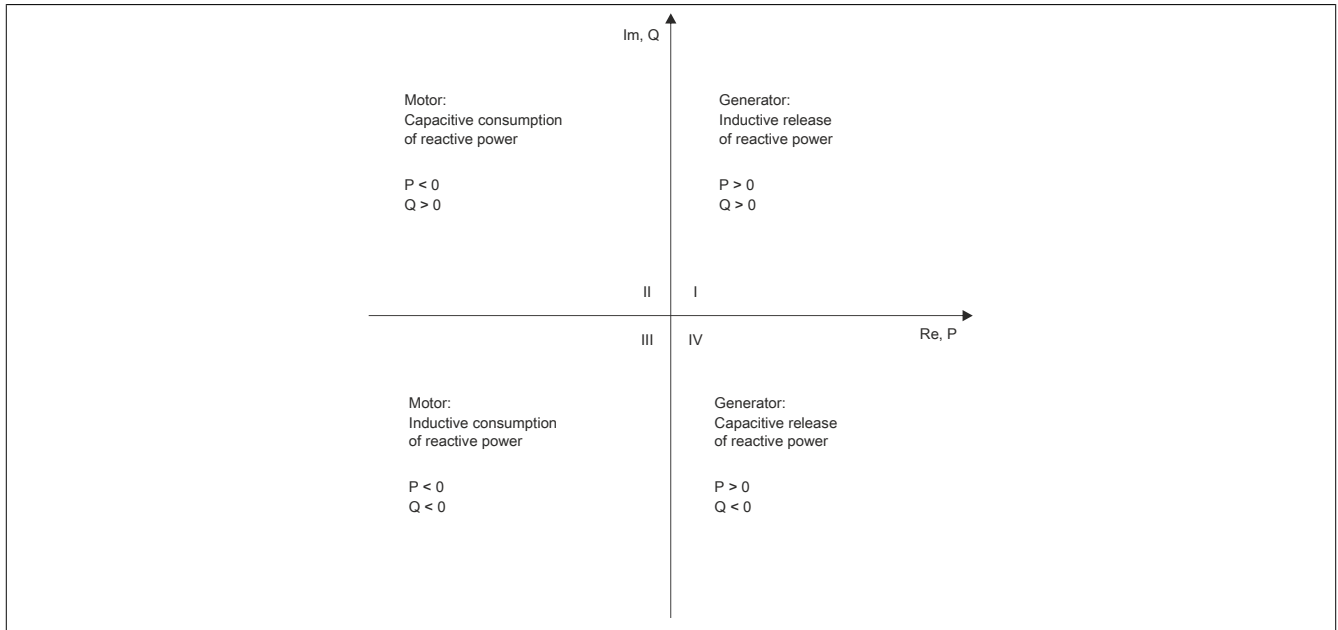

Phase sequence detection

Phase sequence detection is used to detect incorrectly wired voltage and current inputs or if the generator is rotating in the wrong direction (for information about configuration, see register "[ConfigOutput24](#)" on page 2876).

Phase sequence L1, L2 and L3 is monitored for this. If not correct, then an error message is output (see register "[StatusDigitalOutput](#)" on page 2910) and synchronization cannot take place.

9.26.3.17 Generator operating modes

The operating modes possible for the generator are illustrated in this 4 quadrant diagram.

Quadrant I

Generator operation, inductive release of reactive power:

- The active power P and the reactive power Q are greater than 0.
- The phase angle ϕ is between 0 and 90° . This means that U keeps ahead of I .

Example: $\phi = 30^\circ$

Quadrant II

Motor operation, capacitive reactive power consumption:

- The active power P is less than 0 while the reactive power Q is greater than 0.
- The phase angle ϕ is between 90 and 180° . This means that U keeps ahead of I .

Example: $\phi = 150^\circ$

**Quadrant III**

Motor operation, inductive reactive power consumption:

- The active power P and the reactive power Q are less than 0.
- The phase angle ϕ is between -90 and -180° . This means that U lags behind I .

Example: $\phi = -150^\circ$

Quadrant IV

Generator operation, capacitive release of reactive power:

- The active power P is greater than 0 while the reactive power Q is less than 0.
- The phase angle ϕ is between 0 and -90° . This means that U lags behind I.

Example: $\phi = -30^\circ$

Power factor of the generator

The power factor is a product of the ratio between the active power P and apparent power S. With sinusoidal values, this corresponds to the cosine of the phase shift angle ϕ .

$$|\text{Power factor}| = \left| \frac{P}{S} \right|$$

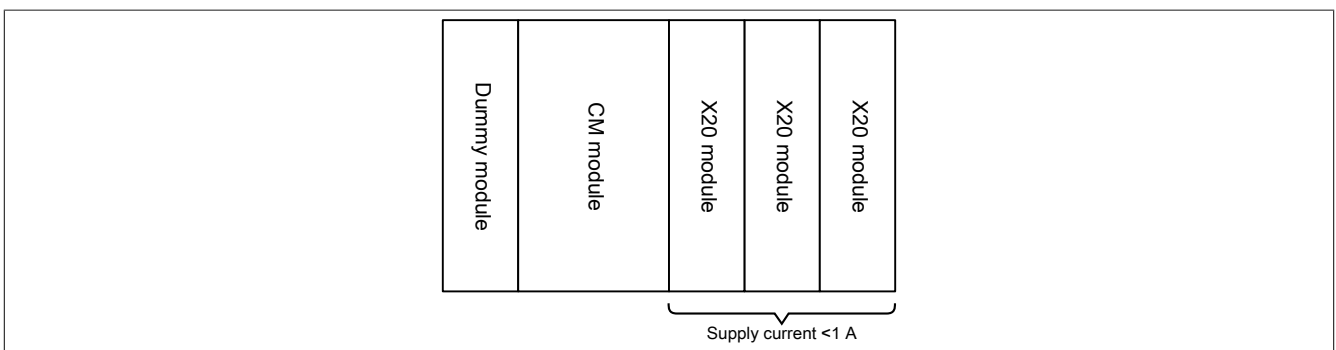

The module derives the sign used for the power factor from the signs used with the P and Q values. In this way, it depends on the generator's operating mode:

| Sign | Description |
|----------|--|
| Positive | <ul style="list-style-type: none"> • Quadrant I or III, P and Q positive or P and Q negative • Inductive release of reactive power or inductive reactive power consumption |
| Negative | <ul style="list-style-type: none"> • Quadrant II or IV, P negative and Q positive or P positive and Q negative • Capacitive release of reactive power or capacitive reactive power consumption |

9.26.3.18 Derating

Derating does not need to be taken into account for operation below 55°C .

For operation above 55°C , a dummy module must be connected to the left of the module. A maximum supply current of 1 A is permitted to pass through the module to the modules connected to the right.

9.26.3.19 Register description

9.26.3.19.1 System requirements

The following minimum versions are recommended to generally be able to use all functions:

- Automation Studio 4.2.5
- Automation Runtime G4.26

9.26.3.19.2 General data points

In addition to the registers described in the register description, the module has additional general data points. These are not module-specific but contain general information such as serial number and hardware variant.

General data points are described in section "[General data points](#)" on page 3790.

9.26.3.19.3 Function model 0 - Standard

1) This configuration register has a dual design. The register with "Read" in the name allows the configured value to be read back.

9.26.3.19.3.1 Using the module on the bus controller

Function model 254 "Bus controller" is used by default only by non-configurable bus controllers. All other bus controllers can use other registers and functions depending on the fieldbus used.

For detailed information, see ["Using I/O modules on the bus controller" on page 3789](#).

9.26.3.19.4 Configuration registers

9.26.3.19.4.1 General registers

Mains settings

Name:

ConfigOutput68

ConfigOutput68Read

This register is used to configure the module on the connected mains.

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|-------------------------------|----------|---|
| 0 - 1 | Generator mains configuration | 00 | 3-phase network with neutral conductor |
| | | 01 | 3-phase mains without neutral conductor |
| | | 10 to 11 | Reserved |
| 2 - 3 | Busbar configuration | 00 | 3-phase network with neutral conductor |
| | | 01 | 3-phase mains without neutral conductor |
| | | 10 to 11 | Reserved |
| 4 - 5 | Mains configuration | 00 | 3-phase network with neutral conductor |
| | | 01 | 3-phase mains without neutral conductor |
| | | 10 | Sync network 1 / Sync network 2 |
| | | 11 | Reserved |
| 6 - 7 | Reserved | 0 | |
| 8 - 9 | Generator mains ground | 00 | No phases grounded |
| | | 01 | L1 grounded |
| | | 10 | L2 grounded |
| | | 11 | L3 grounded |
| 10 - 11 | Busbar ground | 00 | No phases grounded |
| | | 01 | L1 grounded |
| | | 10 | L2 grounded |
| | | 11 | L3 grounded |
| 12 - 13 | Sync Mains 1 ground | 00 | No phases grounded |
| | | 01 | L1 grounded |
| | | 10 | L2 grounded |
| | | 11 | L3 grounded |
| 14 - 15 | Sync Mains 2 ground | 00 | No phases grounded |
| | | 01 | L1 grounded |
| | | 10 | L2 grounded |
| | | 11 | L3 grounded |

Mains without neutral conductor

If configured as "3-phase mains without neutral conductor", the potential of the neutral conductor is calculated from the 3 phases ("virtual neutral point").

The phase voltages are then measured in relation to this "virtual neutral point".

Mains with ground

If one of the phases of a mains system is grounded, then it must be configured as such. Otherwise, it is possible that the module will report a phase failure that blocks the mains synchronization function.

Monitoring functions disabled:

- Phase failure monitoring is not carried out for the phase configured as "grounded".
- Phase sequence monitoring is not performed on 2-phase mains that are grounded.

Mains configuration

The mains can be used as two 2-phase synchronization mains or combined into a 3-phase mains.

If the mains configuration is set to "3-phase mains" then the monitoring functions will be enabled for these combined mains.

Nominal voltage range, nominal current range and Aron circuit

Name:

ConfigOutput20

ConfigOutput20Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|---|-------|---|
| 0 | Nominal voltage range of generator mains | 0 | Voltage 100 V |
| | | 1 | Voltage 400 V |
| 1 | Nominal voltage range of busbar | 0 | Voltage 100 V |
| | | 1 | Voltage 400 V |
| 2 | Nominal voltage range of Sync Mains 1 | 0 | Voltage 100 V |
| | | 1 | Voltage 400 V |
| 3 | Nominal voltage range of Sync Mains 2 | 0 | Voltage 100 V |
| | | 1 | Voltage 400 V |
| 4 | Nominal current range of the generator mains | 0 | Current range 1 A |
| | | 1 | Current range 5 A |
| 5 | Switch to power measurement principle of Aron circuit | 0 | Aron circuit disabled: Three-phase supply with neutral line |
| | | 1 | Aron circuit enabled: Three-phase supply without neutral line |
| 6 - 7 | Reserved | 0 | |

Nominal frequency (f_{Nom})

Name:

ConfigOutput10

ConfigOutput10Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|--------------|-----------------------------|------------|
| UINT | 4800 to 6200 | corresponds to 48 to 62 Hz. | 0.01 Hz |

General configuration register

Name:

ConfigOutput24

ConfigOutput24Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|----------|---|
| 0 - 1 | DO5 function | 00 | DO5 is freely available to the user |
| | | 01 | Monitoring output of the mains |
| | | 10 | DO5 is freely available to the user or can be used as a mains monitoring output (the two signals are linked with an OR) |
| | | 11 | Reserved |
| 2 - 3 | DO6 function | 00 | DO6 is freely available to the user |
| | | 01 | Synchronization output (control of power switch) |
| | | 10 to 11 | Reserved |
| 4 | Definition of rotational direction monitoring of all mains | 0 | Right rotating field |
| | | 1 | Left rotating field |
| 5 - 6 | DO1 function | 00 | Monitoring output of the generator |
| | | 01 | DO1 is freely available to the user. |
| | | 10 | DO1 is freely available to the user or can be used as a monitoring output of the generator (both signals are linked logically by an OR operator). |
| | | 11 | Reserved |
| 7 | Reserved | 0 | |

Trigger bits

Name:

ConfigOutput23

ConfigOutput23Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------------------|-------|--|
| 0 | Reset unbalanced load meter | 0 | Unbalanced load meter not set to 0 |
| | | 1 | On rising edge: Unbalanced load meter set to 0 |
| 1 - 7 | Reserved | 0 | |

9.26.3.19.4.2 Generator mains**Nominal voltage of generator mains (U_{NomGen})**

Name:

ConfigOutput02

ConfigOutput02Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|------------------------------|------------|
| UINT | 70 to 65000 | Corresponds to 70 to 65000 V | 1 V |

Multiplier for generator mains

Name:

ConfigOutput06

ConfigOutput06Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

The value 100 corresponds to a multiplication factor of 1 (measured value not changed).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------------------|------------|
| UINT | 1 to 65535 | Corresponds to 0.01 to 655.35 | 0.01 |

Nominal current of generator mains (I_{Nom})

Name:

ConfigOutput04

ConfigOutput04Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-----------------------------|------------|
| UINT | 0 to 65000 | Corresponds to 0 to 65000 A | 1 A |

Multiplier for current transformer

Name:

ConfigOutput09

ConfigOutput09Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|---------------------------|------------|
| UINT | 1 to 65535 | Corresponds to 1 to 65535 | 1 |

Turns generator mains functions on/off

Name:

ConfigOutput21

ConfigOutput21Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|---|
| 0 | Error acknowledgment mode | 0 | Error bits are reset by the module |
| | | 1 | Error bits are reset by the user |
| 2 - 3 | Check all overvoltages and undervoltages ¹⁾ | 00 | 3 phase voltages |
| | | 01 | 3 line-to-line voltages |
| | | 10 | 3 line-to-line and 3 phase voltages |
| | | 11 | Reserved |
| 4 - 5 | Reserved | 0 | |
| 6 | Power measurement mode | 0 | Total output - Including the harmonic component |
| | | 1 | Fundamental power - 1st harmonic only |
| 7 | Reserved | 0 | |

1) For information about configuring limit values, see "Generator monitoring" on page 2879.

Power measurement mode

In real transmission networks, neither the voltages nor the currents are strictly sinusoidal. This means: The fundamental frequencies are generally subject to strong harmonics.

By default, the module always accounts for the contributions of the fundamental frequency as well as the harmonics. In addition to the voltage and current measured values, this also affects the power measurements.

When controlling with reactive power in applications, the part of the reactive power coming from the harmonic frequencies (distortion reactive power) can have negative effects. Only the displacement reactive power should be controlled (i.e. the reactive power component of the fundamental frequency). In particular, this can make a control to displacement reactive power = 0 ($\cos \varphi = 1$) impossible.

This is why the module offers the possibility of accounting for only the fundamental frequency (1st harmonic) for power measurement, when necessary. This primarily serves to filter out the distortion reactive power. However, all other measured values associated with the power measurement as well as the corresponding generator protection functions are affected when re-configuring the power measurement to the fundamental frequency.

The voltage and current measured values from the generator mains are **not** affected. Just as before (as with the other voltage supply systems), they also always include the contribution of harmonics regardless of the mode being used for power measurement.

| Measured value / Functionality | Corresponding data point | Corresponding output | Remarks/Details |
|--|--------------------------------|----------------------|--|
| Active power | AnalogInput19 | | $P \rightarrow P_H1$ |
| Reactive power | AnalogInput20 | | $Q \rightarrow Q_H1$ |
| Apparent power | AnalogInput21 | | $S \rightarrow S_H1$ |
| Power factor | AnalogInput23 | | Power factor $\rightarrow \cos \varphi$ $ \cos \varphi = \cos(\arctan(Q_H1/P_H1))$ The signs for $\cos \varphi$ are described in section "Generator operating modes" on page 2865. "I" and "U" must be replaced by the respective 1st harmonics "I_H1" and "U_H1". |
| Maximum total active power | ConfigOutput52 | | Changing the parameter "Power measurement mode" during runtime has no immediate effect on any of these registers or the internal energy meters (e.g. meter reset). It only determines the summands or comparison value that is effective immediately (total output / fundamental frequency power). |
| Active energy meter for supply | ConfigOutput54 | | |
| Reactive energy meter for supply | ConfigOutput55 | | |
| Active energy meter for reference | ConfigOutput71 | | |
| Reactive energy meter for reference | ConfigOutput72 | | |
| Energy meter output | | DO 2 | |
| Generator monitoring function: Capacitive reactive power | StatusInput10 | DO 1 | |
| Generator monitoring function: Generator overload | StatusInput31 | DO 1 | |
| Generator monitoring function: Generator feedback | StatusInput32 | DO 1 | |

Low-pass filter for total power ratings

Name:

ConfigOutput41
ConfigOutput41Read

Parameter for delay time of the low-pass filter of the total power values P, Q and S or P_H1, Q_H1 and S_H1 (see "[Power measurement mode](#)" on page 2878). The maximum total power values are recorded independently of this without being filtered.

This parameter is used as a delay element so that current or voltage fluctuations have less effect on how the calculated power values are represented. The damping behavior of the low-pass filter acts in accordance with the configurable time constant of a decaying e-function.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|----------------------------|------------|
| UINT | 0 to 300 | Corresponds to 0 to 300 ms | 1 ms |

Filter cycles for real-time values

Name:

ConfigOutput125
ConfigOutput125Read

This register influences the pre-filtering of the instantaneous values for generator voltage and current in the module. When using task classes that are a multiple of the X2X cycle, the cutoff frequency of the pre-filter must be adjusted to avoid aliasing the instantaneous values.

This is done by specifying the task cycle time as a multiple of the X2X cycle time. If the calculated total value (i.e. Pre-filter time * X2X cycle time) exceeds 64.77 ms, it is limited to this.

The value of this register can be read back.

| Data type | Values | Information | Resolution |
|-----------|-----------|-------------------------------------|------------|
| UINT | 1 to 2000 | Corresponds to 1 to 2000 X2X cycles | 1 cycle |

9.26.3.19.4.3 Generator monitoring**Overvoltage limit of generator mains (U_{max})**

Name:

ConfigOutput16 (1st value)
ConfigOutput118 (2nd value)
ConfigOutput16Read (1st value)
ConfigOutput118Read (2nd value)

If the value of one of the generator voltages configured in the "[ConfigOutput21](#)" on page 2878 register exceeds the value set here, then the "Overvoltage" error message (register "[StatusInputPacked01](#)" on page 2911) or "Overvoltage2" (register "[StatusInputPacked05](#)" on page 2914) is indicated after the delay time has expired and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of U _{NomGen} | 0.1% |

Response time for generator overvoltage (U_{max})

Name:

ConfigOutput26 (1st time)
ConfigOutput119 (2nd time)
ConfigOutput26Read (1st time)
ConfigOutput119Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register. A response time of up to 80 s can be configured for a monitor.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------------------|--|------------|
| UINT | 5 to 100 5 to 800 | Corresponds to 0.5 to 10 s Corresponds to 0.5 to 80 s | 0.1 s |

Undervoltage limit of generator mains (U_{min})

Name:

ConfigOutput27 (1st value)

ConfigOutput59 (2nd value)

ConfigOutput27Read (1st value)

ConfigOutput59Read (2nd value)

If the value of one of the generator voltages configured in the "ConfigOutput21" on page 2878 register falls below the value set here, then the "Undervoltage" or "Undervoltage2" error message (register "StatusInputPacked01" on page 2911) is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of U_{NomGen} | 0.1% |

Response time for generator undervoltage (U_{min})

Name:

ConfigOutput28 (1st time)

ConfigOutput65 (2nd time)

ConfigOutput28Read (1st time)

ConfigOutput65Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register. A response time of up to 80 s can be configured for a monitor.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------------------|--|------------|
| UINT | 5 to 100 5 to 800 | Corresponds to 0.5 to 10 s Corresponds to 0.5 to 80 s | 0.1 s |

Generator over-frequency (f_{max})

Name:

ConfigOutput29 (1st frequency)

ConfigOutput122 (2nd frequency)

ConfigOutput29Read (1st frequency)

ConfigOutput122Read (2nd frequency)

If the value of the generator frequency exceeds the percent value set here in relation to the nominal frequency, then the error message "Overfrequency" (register "StatusInputPacked01" on page 2911) or "Overfrequency 2" (register "StatusPacked05" on page 2914) is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|----------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} | 0.1% |

Response time for generator over-frequency (f_{max})

Name:

ConfigOutput30 (1st time)

ConfigOutput123 (2nd time)

ConfigOutput30Read (1st time)

ConfigOutput123Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|------------------|------------|
| UINT | 5 to 100 | For 0.5 for 10 s | 0.1 s |

Generator under-frequency (f_{min})

Name:

ConfigOutput31 (1st frequency)
 ConfigOutput120 (2nd frequency)
 ConfigOutput31Read (1st frequency)
 ConfigOutput120Read (2nd frequency)

If the value of the generator frequency falls below the percent value set here in relation to the nominal frequency, then the error message "Underfrequency" (register "StatusInputPacked01" on page 2911) or "Underfrequency 2" (register "StatusInputPacked05" on page 2914) is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|----------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} | 0.1% |

Response time for generator under-frequency (f_{min})

Name:

ConfigOutput32 (1st time)
 ConfigOutput121 (2nd time)
 ConfigOutput32Read (1st time)
 ConfigOutput121Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Generator voltage asymmetry (U_{as})

Name:

ConfigOutput33
 ConfigOutput33Read

This trigger value, specified as a percentage, is based on the nominal voltage of the generator. If the difference between the three line-to-line voltages of the generator mains exceeds the configured limit value, then the error message "Voltage asymmetry" is indicated (register "StatusInputPacked01" on page 2911) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

For this to happen, only one of these voltages has to exceed the respective limit value (in either the positive or negative direction).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|------------------------------|------------|
| UINT | 0 to 300 | For 0 to 30% of U_{NomGen} | 0.1% |

Response time for generator voltage asymmetry (U_{as})

Name:

ConfigOutput34
 ConfigOutput34Read

This error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Load time constant for current asymmetry (K1)

Name:

ConfigOutput35

ConfigOutput35Read

The dependent delayed unbalanced load monitoring function (see "[Dependent delayed unbalanced load monitoring](#)" on page 2882) continually monitors the AC currents coming from the main current converters and continually calculates the present unbalanced load current. This is compared with the threshold value, which is calculated using the load time constants. If this threshold value is exceeded, the error message "Current asymmetry" is indicated (register "[StatusInputPacked01](#)" on page 2911) and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|---------------------|------------|
| UINT | 1 to 65535 | For 0.1 to 6553.5 s | 0.1 s |

Unbalanced load constant (K2)

Name:

ConfigOutput109

ConfigOutput109Read

The boundary between continuous operation and short-term operation is defined by the unbalanced load constant K2 (see "[Dependent delayed unbalanced load monitoring](#)" on page 2882).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|---------|------------------|------------|
| UINT | 8 to 15 | For 0.08 to 0.15 | 0.01 |

Dependent delayed unbalanced load monitoring

Unbalanced load monitoring protects against unbalanced load in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An unbalanced load can be caused by uneven current distribution in the mains due to unbalanced load, asymmetrical short circuits, line interruptions or switching operations. Unbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An unbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an unbalanced load occurs, the characteristics that trigger unbalanced load protection should be adapted to the thermal characteristics of the generator. Unbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

When unbalanced load protection is tripped can be calculated using the following formula:

| Operating mode | Formula |
|----------------------|--|
| Short-term operation | $t = \frac{K1}{\left(\frac{I_2}{I_{Nom}}\right)^2 - K2^2}$ |
| Continuous operation | $\frac{I_2}{I_{Nom}} \leq K2 \rightarrow t = \infty$ |
| Key | |
| t | Calculated tripping time |
| K1 | Valid load time constant for the generator [s] |
| K2 | Unbalanced load constant |
| I ₂ | Calculated inverse current / unbalanced load current [A] |
| I _{Nom} | Nominal current for the generator [A] |

To calculate the tripping time instant, the scan duration of the measurement system (i.e. 20 ms for 50 Hz voltage) is divided by the calculated trigger time, and the results are continually added up. With short-term operation, the value of the summands increases; with continuous operation, it decreases. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

The boundary between continuous operation and short-term operation is defined by the unbalanced load constant K2.

Information:

When the generator is at a standstill, the summand is neither reset nor is its value reduced.

Nominal current on generator mains for unbalanced load protection

Name:

ConfigOutput124

ConfigOutput124Read

The nominal current for unbalanced load protection can be set separately. If the value is set to 0, the normal nominal current is used for calculations.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|------------------|------------|
| UINT | 0 to 65000 | For 0 to 65000 A | 1 A |

Maximum limit of neutral conductor current

Name:

ConfigOutput36

ConfigOutput36Read

Configurable limit for the neutral conductor current. If the value is exceeded, then the error message "Maximum neutral conductor current" is indicated (register "[StatusInputPacked01](#)" on [page 2911](#)) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-----------------------------------|------------|
| UINT | 0 to 1000 | For 0 to 100% of I _{Nom} | 0.1% |

Response time for neutral conductor current monitor

Name:

ConfigOutput37

ConfigOutput37Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Short circuit current

Name:

ConfigOutput38

ConfigOutput38Read

If the value of the generator current exceeds the percentage based on the converter's nominal current set here, then the error message "Short circuit current" is indicated (register "[StatusInputPacked01](#)" on page 2911) and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|--------------|------------------------------|------------|
| UINT | 1000 to 5000 | For 100 to 500% of I_{Nom} | 0.1% |

Response time for short circuit current

Name:

ConfigOutput39

ConfigOutput39Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 4 to 500 | For 0.04 to 5 s | 0.01 s |

Rating-dependent overcurrent

Name:

ConfigOutput42

ConfigOutput42Read

The response value percentage is based on the nominal current of the generator. If the response value is exceeded, then the error message "Rating-dependent overcurrent" is indicated (register "[StatusInputPacked01](#)" on page 2911) and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|--------------|------------------------------|------------|
| UINT | 1000 to 2000 | For 100 to 200% of I_{Nom} | 0.1% |

Rating-dependent overcurrent monitoring

A generator that is operated at its nominal current I_{Nom} normally reaches about half of its maximum thermal load. Operating it above the rated current I_{Nom} result in additional warming, which is permitted until the maximum temperature is reached. The highest permissible continuous temperature is determined by the class of the insulation material used in the generator.

Based on the settings and the current measurement, the device forms an internal model based on an I^2t characteristic curve of the generator temperature. This allows the heat capacity of the generator to be completely utilized for short overloads while at the same time providing full protection. The configurable parameters for determining the machine model include the nominal current I_{Nom} of the generator and the time multiplier.

Integration coefficient for rating-dependent overcurrent (iths)

Name:

ConfigOutput43

ConfigOutput43Read

To calculate the tripping time instant, the sampling duration of the measurement system is divided by the calculated trigger time (t). The results are continually added up. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|---------|--------------|------------|
| UINT | 1 to 20 | For 0.1 to 2 | 0.1 |

For a constant overcurrent, the trigger characteristic curve can be calculated based on the following formula:

$$t = \frac{0.14}{\left(\frac{I}{I_N}\right)^{0.02} - 1} * iths$$

Key:

| | |
|-------|---|
| t | Tripping time [s] |
| I | The highest value of the 3 phase currents [A] |
| I_N | Rating-dependent overcurrent [A] |
| iths | Integration coefficient |

Trigger characteristic curve in accordance with IEC 255-4 (normal, inverse)

The monitor function can be reset by restarting the module or by falling below the overcurrent value so that the results of the continuous addition decrease according to the formula.

Capacitive reactive power

Name:

ConfigOutput44

ConfigOutput44Read

The capacitive reactive power for the generator is monitored to determine if it falls below the defined response value. In this way, monitoring the capacitive reactive power can be used to detect exciter failure. If the response value is fallen below, then the error message "Capacitive reactive power" is indicated (register "[StatusInputPacked01](#)" on [page 2911](#)) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Depending on how the "Power measurement mode" parameter is set in the "[ConfigOutput21](#)" on [page 2878](#) register, either the total reactive power or the fundamental frequency reactive power (displacement reactive power) is compared with the response value.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------------|--------------------------|------------|
| INT | -32768 to 32767 | For -32768 to 32767 kvar | 1 kvar |

Response time for reactive power monitoring

Name:

ConfigOutput45

ConfigOutput45Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Generator overload

Name:

ConfigOutput89

ConfigOutput89Read

If the value of the active power of the generator exceeds the percentage of the generator's nominal power set here, then the error message "Generator overload" is indicated (register "[StatusInputPacked01](#)" on [page 2911](#)) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Depending on how the "Power measurement mode" parameter is set in the "[ConfigOutput21](#)" on [page 2878](#) register, either the total active power or the fundamental frequency active power is compared with the response value.

The nominal power is calculated as follows:

$$P_{\text{NomGen}} = U_{\text{NomGen}} * I_{\text{NomGen}} * \sqrt{3}$$

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--------------------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of P_{NomGen} | 0.1% |

Response time for generator overload

Name:

ConfigOutput90

ConfigOutput90Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

Generator feedback

Name:

ConfigOutput91

ConfigOutput91Read

If the value of the negative active power of the generator falls below the percentage of the generator's nominal power set here, then the error message "Generator feedback" is indicated (register "[StatusInputPacked01](#)" on page [2911](#)) after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Depending on how the "Power measurement mode" parameter is set in the "[ConfigOutput21](#)" on page [2878](#) register, either the total active power or the fundamental frequency active power is compared with the response value.

The nominal power is calculated as follows:

$$P_{\text{NomGen}} = U_{\text{NomGen}} \cdot I_{\text{NomGen}} \cdot \sqrt{3}$$

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|----------------------------------|------------|
| UINT | 0 to 2000 | 0 to 200% of P_{NomGen} | 0.1% |

Response time for generator feedback

Name:

ConfigOutput92

ConfigOutput92Read

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-----------------|------------|
| UINT | 5 to 100 | For 0.5 to 10 s | 0.1 s |

DO1 function

This digital output can be set after the defined response time has elapsed depending on the assignment of the generator mains' monitoring variables (X3). Assignments are made using the "ConfigOutput57" on page 2888 and "ConfigOutput97" on page 2889 registers.

The monitoring variables can be assigned to this input either individually or with additional monitoring variables using an OR connective. This makes it possible to set the relay when there are multiple monitoring variables.

Assigning monitoring functions - 1

Name:

ConfigOutput57

ConfigOutput57Read

The following monitoring functions can be assigned to the monitoring relay using this register:

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|---------|---|-------|------------------------|
| 0 | Overvoltage (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 1 | Undervoltage (or a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 2 | Overfrequency | 0 | Do not assign function |
| | | 1 | Assign function |
| 3 | Underfrequency | 0 | Do not assign function |
| | | 1 | Assign function |
| 4 | Voltage asymmetry | 0 | Do not assign function |
| | | 1 | Assign function |
| 5 | Current asymmetry (unbalanced load) | 0 | Do not assign function |
| | | 1 | Assign function |
| 6 | Neutral conductor current, maximum | 0 | Do not assign function |
| | | 1 | Assign function |
| 7 | Short circuit current | 0 | Do not assign function |
| | | 1 | Assign function |
| 8 | Rating-dependent overcurrent | 0 | Do not assign function |
| | | 1 | Assign function |
| 9 | Capacitive reactive power (exciter failure) | 0 | Do not assign function |
| | | 1 | Assign function |
| 10 | Ready | 0 | Do not assign function |
| | | 1 | Assign function |
| 11 | Generator overload | 0 | Do not assign function |
| | | 1 | Assign function |
| 12 | Generator feedback | 0 | Do not assign function |
| | | 1 | Assign function |
| 13 - 14 | Reserved | 0 | |
| 15 | Undervoltage 2 (one phase) | 0 | Do not assign function |
| | | 1 | Assign function |

Information:

The minimum pulse duration when addressing a monitoring function on the error bit via X2X as well as on the relay is 500 ms.

Assigning monitoring functions - 2

Name:

ConfigOutput97

The following additional monitoring functions can be assigned to the monitoring relay using this register:

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------------------|-------|------------------------|
| 0 | Overvoltage 2 (one phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 1 | Underfrequency 2 | 0 | Do not assign function |
| | | 1 | Assign function |
| 2 | Overfrequency 2 | 0 | Do not assign function |
| | | 1 | Assign function |
| 3 | Q-U protection | 0 | Do not assign function |
| | | 1 | Assign function |
| 4 - 15 | Reserved | 0 | |

Information:

The minimum pulse duration when addressing a monitoring function on the error bit via X2X as well as on the relay is 500 ms.

Q-U protection

Name:

ConfigOutput126

ConfigOutput126Read

If all generator voltages configured in register "[ConfigOutput21](#)" on page 2878 undershoot the value set here and inductive reactive power is simultaneously absorbed (active power $P < 0$ and reactive power $Q < 0$), if configured, error message "Q-U protection" is indicated in register "[StatusInputPacked05](#)" on page 2914 and monitoring relay DO1 is switched after the [time delay](#) has expired.

The values of these registers can be read back.

| Data type | Values | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of the nominal voltage | 0.1% |

Response time for Q-U protection

Name:

ConfigOutput127

ConfigOutput127Read

Response time for triggering Q-U protection. For more information, see "[Q-U protection](#)" on page 2889.

The value of this register can be read back.

| Data type | Values | Information | Resolution |
|-----------|----------|----------------------------|------------|
| UINT | 1 to 100 | Corresponds to 0.1 to 10 s | 0.1 s |

9.26.3.19.4.4 Synchronization mains

(for mains configuration "Sync mains 1 / Sync mains 2")

Nominal voltage of synchronization mains (U_{NomSyn})

Name:

ConfigOutput01

ConfigOutput01Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------------|------------|
| UINT | 70 to 65000 | For 70 to 65000 V | 1 V |

Multiplier for synchronization mains

Name:

ConfigOutput07 (mains 1)

ConfigOutput08 (mains 2)

ConfigOutput07Read (mains 1)

ConfigOutput08Read (mains 2)

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 means a multiplier factor of 1 (measured value not changed).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|--------------------|------------|
| UINT | 1 to 65535 | For 0.01 to 655.35 | 0.01 |

9.26.3.19.4.5 Mains

Mains (for mains configuration "3-phase mains")

Nominal voltage of mains (U_{NomMains})

Name:

ConfigOutput01

ConfigOutput01Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------------|------------|
| UINT | 70 to 65000 | For 70 to 65000 V | 1 V |

Multiplier for mains

Name:

ConfigOutput07

ConfigOutput07Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 means a multiplier factor of 1 (measured value not changed).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|--------------------|------------|
| UINT | 1 to 65535 | For 0.01 to 655.35 | 0.01 |

Enable/disable mains functions

Name:

ConfigOutput22

ConfigOutput22Read

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|--|-------|--|
| 0 | Error acknowledgment mode | 0 | Mains error bits are reset by the module |
| | | 1 | Mains error bits are reset by the user |
| 1 | Phase shift measurement | 0 | Three-phase only |
| | | 1 | Single- or three-phase |
| 2 - 3 | Check all overvoltages and undervoltages ¹⁾ | 00 | 3 phase voltages |
| | | 01 | 3 line-to-line voltages |
| | | 10 | 3 line-to-line and 3 phase voltages |
| | | 11 | Reserved |
| 4 | Configuration of undervoltage monitoring | 0 | 2-point mode |
| | | 1 | 6-point mode |
| 5 - 7 | Reserved | 0 | |

1) For information about configuring limit values, see "Mains voltage monitoring" on page 2892.

9.26.3.19.4.6 Mains monitoring functions

(for "3-phase mains" configuration)

The following mains monitoring functions are available if the network configuration is set to a 3-phase mains (see register "Mains settings" on page 2875).

Mains voltage monitoring

Overvoltage limit of the mains ($U_{\max\text{Mains}}$)

Name:

ConfigOutput73 (1st value)

ConfigOutput98 (2nd value)

ConfigOutput73Read (1st value)

ConfigOutput98Read (2nd value)

If the value of one of the mains voltages configured in the "ConfigOutput22" on page 2891 register exceeds the value set here, then the "Overvoltage" error message (register "StatusInputPacked02" on page 2912) or "Overvoltage 2" (register "StatusInputPacked04" on page 2913) is indicated after the delay time has expired and, if configured, the DO5 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 2000 | For 0 to 200% of U_{NomMains} | 0.1% |

Mains overvoltage dropout threshold

Name:

ConfigOutput128 (1st value)

ConfigOutput130 (2nd value)

ConfigOutput128Read (1st value)

ConfigOutput130Read (2nd value)

If the dropout threshold is undershot within the response time after the overvoltage limit value has been overshoot by a mains voltage, the monitor is not triggered and the response time starts again from the beginning when the overvoltage limit value is overshoot again. If values are selected for the dropout threshold that are greater than or equal to the overvoltage limit value, then the dropout threshold is disabled.

The values of these registers can be read back.

| Data type | Values | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of the nominal voltage | 0.1% |

Response time for mains overvoltage (U_{MaxMains})

Name:

ConfigOutput82 (1st time)

ConfigOutput99 (2nd time)

ConfigOutput82Read (1st time)

ConfigOutput99Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Mains over-frequency ($f_{\max\text{Mains}}$)

Name:

ConfigOutput75 (1st frequency)

ConfigOutput102 (2nd frequency)

ConfigOutput75Read (1st frequency)

ConfigOutput102Read (2nd frequency)

If the value of the mains frequency exceeds the percent value set here in relation to the nominal frequency, then the error message "Overfrequency" (register "StatusInputPacked02" on page 2912) or "Overfrequency 2" (register "StatusInputPacked04" on page 2913) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-----------------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} | 0.1% |

Overfrequency dropout threshold

Name:

ConfigOutput132 (1st value)

ConfigOutput134 (2nd value)

ConfigOutput132Read (1st value)

ConfigOutput134Read (2nd value)

If the dropout threshold is undershot within the response time after the overfrequency limit value has been overshoot by a mains voltage, the monitor is not triggered and the response time starts again from the beginning when the overfrequency limit value is overshoot again. If values are selected for the dropout threshold that are greater than or equal to the overfrequency limit value, then the dropout threshold is disabled.

The values of these registers can be read back.

| Data type | Values | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of the rated frequency | 0.1% |

Response time for mains over-frequency ($f_{\max\text{Mains}}$)

Name:

ConfigOutput84 (1st time)

ConfigOutput103 (2nd time)

ConfigOutput84Read (1st time)

ConfigOutput103Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Mains under-frequency ($f_{\min\text{Mains}}$)

Name:

ConfigOutput76 (1st frequency)

ConfigOutput104 (2nd frequency)

ConfigOutput76Read (1st frequency)

ConfigOutput104Read (2nd frequency)

If the value of the mains frequency falls below the percent value set here in relation to the nominal frequency, then the error message "Underfrequency" (register "StatusInputPacked02" on page 2912) or "Underfrequency 2" (register "StatusInputPacked04" on page 2913) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-----------------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of f_{Nom} | 0.1% |

Underfrequency dropout threshold

Name:

ConfigOutput133 (1st value)

ConfigOutput135 (2nd value)

ConfigOutput133Read (1st value)

ConfigOutput135Read (2nd value)

If the dropout threshold is overshot within the response time after the underfrequency limit value has been undershot by a mains voltage, the monitor is not triggered and the response time starts again from the beginning when the underfrequency limit value is undershot again. If values are selected for the dropout threshold that are less than or equal to the underfrequency limit value, then the dropout threshold is disabled.

The values of these registers can be read back.

| Data type | Values | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of the rated frequency | 0.1% |

Response time for mains under-frequency ($f_{\min\text{Mains}}$)

Name:

ConfigOutput85 (1st time)

ConfigOutput105 (2nd time)

ConfigOutput85Read (1st time)

ConfigOutput105Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Mains voltage asymmetry (U_{asMains})

Name:

ConfigOutput77

ConfigOutput77Read

This trigger value, specified as a percentage, is based on the nominal voltage of the mains. If the difference between the 3 line-to-line voltages of the mains exceeds the configured limit value, then the error message "Voltage asymmetry" is indicated (register "[StatusInputPacked02](#)" on page 2912) after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

For this to happen, only one of these voltages has to exceed the respective limit value (in either the positive or negative direction).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|---------------------------------------|------------|
| UINT | 0 to 300 | For 0 to 30% of U_{NomMains} | 0.1% |

Response time for the mains voltage asymmetry (U_{asMains})

Name:

ConfigOutput86

ConfigOutput86Read

This error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------------|------------|
| UINT | 5 to 100 | For 0.005 to 0.1 s | 0.001 s |

Undervoltage monitoring in 2-point mode

2 independent limit values and response times can be defined for undervoltage monitoring.

Undervoltage limit of the mains ($U_{\min\text{Mains}}$)

Name:

ConfigOutput74

ConfigOutput74Read

If the value of one of the mains voltages configured in the "ConfigOutput22" on page 2891 register falls below the value set here, then the "Undervoltage" error message (register "StatusInputPacked02" on page 2912) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 2000 | For 0 to 200% of U_{NomMains} | 0.1% |

Mains undervoltage dropout threshold

Name:

ConfigOutput129 (1st value)

ConfigOutput131 (2nd value)

ConfigOutput129Read (1st value)

ConfigOutput131Read (2nd value)

If the dropout threshold is overshoot within the response time after the undervoltage limit value has been undershot by a mains voltage, the monitor is not triggered and the response time starts again from the beginning when the undervoltage limit value is undershot again. If values are selected for the dropout threshold that are less than or equal to the undervoltage limit value, then the dropout threshold is disabled.

The values of these registers can be read back.

| Data type | Values | Information | Resolution |
|-----------|-----------|---|------------|
| UINT | 0 to 2000 | Corresponds to 0 to 200% of the nominal voltage | 0.1% |

Response time for mains undervoltage ($U_{\min\text{Mains}}$)

Name:

ConfigOutput83 (1st time)

ConfigOutput101 (2nd time)

ConfigOutput83Read (1st time)

ConfigOutput101Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Undervoltage limit 2 of the mains ($U_{\min\text{Mains}}$)

Name:

ConfigOutput100

ConfigOutput100Read

If the value of one of the linked mains voltages falls below the value set here, then the "Undervoltage" error message (register "StatusInputPacked02" on page 2912) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|------------------------------------|------------|
| UINT | 0 to 2000 | 0 to 200% of U_{NomMains} | 0.1% |

Undervoltage monitoring in 6-point mode

Up to 6 limit values and response times can be set for undervoltage monitoring. If not all 6 points are required, then unused limit values and response times should be set to 0.

Note that for each point, the specified limit value and response time must be greater than or equal to the preceding point ($P1 \leq P2 \leq P3$, etc.).

The defined points are used to create a limit value curve. If the voltage drops below the curve and a response time has expired, the error message "Undervoltage" is signaled ("[StatusInputPacked02](#)" on [page 2912](#) register). If configured, the D05 monitoring relay is also switched.

A faulty undervoltage monitoring configuration also triggers the "Undervoltage" error message, and monitor relay DO5 is switched if configured to do so (e.g. $P1 > P2$ and $P2$ not equal to (0% / 0 ms)).

The types of voltages to be monitored are specified in the mains configuration ("[ConfigOutput22](#)" on [page 2891](#) register):

- Line-to-line voltages
- Phase voltages
- Line-to-line and phase voltages

As soon as one of the monitored voltages drops below the limit curve, the corresponding time counter begins counting. The time counter is reset when all voltages are once again equal to or higher than the defined value.

The "Undervoltage" error message is generated when one of the time counters crosses over the limit curve.

Example 1 with 3 points:

In this example, 3 limit values are defined, along with the corresponding response times:

- P1 (70% / 150 ms)
- P2 (70% / 700 ms)
- P3 (90% / 1500 ms)
- P4 (0% / 0 ms)
- P5 (0% / 0 ms)
- P6 (0% / 0 ms)

**Notes regarding limit curve**

- The red line marks the lowest permitted value for monitored voltages.
- If 2 consecutive points have the same limit value, then the response time of the first point is applied. In the example above, this situation is shown with points 1 and 2.
- Between points 2 and 3 the curve has a positive linear slope. If one of the monitored voltages drops in this area, the module calculates the appropriate response time.

Determining the response time

- 1) Find voltage value on Y axis
- 2) Locate intersection on curve
- 3) Read the response time on the X axis

Example 2 with 4 points:

In this example, 4 limit values are defined, along with the corresponding response times:

- P1 (30% / 150 ms)
- P2 (70% / 700 ms)
- P3 (70% / 1500 ms)
- P4 (90% / 1500 ms)
- P5 (0% / 0 ms)
- P6 (0% / 0 ms)

**Notes regarding limit curve**

- The red line marks the lowest permitted value for monitored voltages.
- Between points 1 and 2 the curve has a positive linear slope. If one of the monitored voltages drops in this area, the module calculates the appropriate response time.
- If 2 consecutive points have the same limit value, then the response time of the first point is applied. In the example, this situation is shown with points 2 and 3.
- Points 1 and 2 are connected directly by a line with a positive slope. To avoid a direct connection between points 2 and 4, one would have to define another point between them with the same limit as point 2 and the same response time as point 4. In this case, that is point 3.

Determining the response time

- 1) Find voltage value on Y axis
- 2) Locate intersection on curve
- 3) Read the response time on the X axis

Undervoltage limit of the microgrid (U_{MinMains})

Name:

ConfigOutput74 (1st mains)
 ConfigOutput100 (2nd mains)
 ConfigOutput110 (3rd mains)
 ConfigOutput112 (4th mains)
 ConfigOutput114 (5th mains)
 ConfigOutput116 (6th mains)
 ConfigOutput74Read (1st mains)
 ConfigOutput100Read (2nd mains)
 ConfigOutput110Read (3rd mains)
 ConfigOutput112Read (4th mains)
 ConfigOutput114Read (5th mains)
 ConfigOutput115Read (6th mains)

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|------------------------------------|------------|
| UINT | 0 to 2000 | 0 to 200% of U_{NomMains} | 0.1% |

Response time for mains undervoltage (U_{minMains})

Name:

ConfigOutput83 (1st mains)
 ConfigOutput101 (2nd mains)
 ConfigOutput111 (3rd mains)
 ConfigOutput113 (4th mains)
 ConfigOutput115 (5th mains)
 ConfigOutput117 (6th mains)
 ConfigOutput83Read (1st mains)
 ConfigOutput101Read (2nd mains)
 ConfigOutput111Read (3rd mains)
 ConfigOutput113Read (4th mains)
 ConfigOutput115Read (5th mains)
 ConfigOutput117Read (6th mains)

The values of these registers can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|-------------------|------------|
| UINT | 5 to 60000 | For 0.005 to 60 s | 0.001 s |

Microgrid monitoring

A microgrid is a small mains power grid that only supplies a limited area and generally is not connected to other mains grids, which means it can function autonomously. This is in contrast to a synchronous grid, in which multiple smaller mains grids are connected together and synchronized.

With microgrid monitoring, the mains is monitored for over/undervoltage. After a defined response time elapses, a corresponding error message is generated. Microgrid monitoring always checks the line-to-line voltages independently of the configuration in the "ConfigOutput22" on page 2891 register.

Overvoltage limit of the mains ($U_{\max\text{Mains}}$)

Name:

ConfigOutput106

ConfigOutput106Read

If the value of one of the linked mains voltages exceeds the value set here, then the "Microgrid monitoring" error message (register "StatusInputPacked04" on page 2913) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|------------------------------------|------------|
| UINT | 0 to 2000 | 0 to 200% of U_{NomMains} | 0.1% |

Undervoltage limit of the mains ($U_{\min\text{Mains}}$)

Name:

ConfigOutput107

ConfigOutput107Read

If the value of one of the linked mains voltages falls below the value set here, then the "Microgrid monitoring" error message (register "StatusInputPacked04" on page 2913) is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|--|------------|
| UINT | 0 to 2000 | For 0 to 200% of U_{NomMains} | 0.1% |

Response time for microgrid limit

Name:

ConfigOutput108

ConfigOutput108Read

An error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------------|------------|
| UINT | 5 to 200 | For 0.005 to 0.2 s | 0.001 s |

Phase shift monitoring

A phase shift is an abrupt change to the voltage curve that can be caused by a significant change to the load.

In this case, the device recognizes a single change to the period duration. This changed period duration is compared with the calculated average value from past measurements. Monitoring takes place for three phases and if desired also for a single phase. The phase shift monitoring function is only active if the mains voltage is higher than the set percentage value based on the nominal voltage for the converter.

If the response value is exceeded, the error message "Phase shift" is indicated (register "StatusInputPacked02" on page 2912) and, if configured, the DO5 monitoring relay is switched.

Phase shift monitoring response time

A phase shift is indicated on output DO5 within 2 ms after detection of the phase shift (i.e. after zero crossing of the extended/shortened period), as long as this is configured accordingly.

Phase shift detection

Phase shift detection is configured in the "ConfigOutput22" on page 2891 register.

| Type of monitoring | Description |
|--|--|
| Only three-phase monitoring | Triggering takes place if the limit value for three-phase monitoring was exceeded on all 3 phases within 2 periods. |
| Single-phase or three-phase monitoring | Triggering takes place: <ul style="list-style-type: none"> • If the limit value for single-phase monitoring is exceeded on at least one of the 3 phases • If the limit value for three-phase monitoring was exceeded on all 3 phases within 2 periods. |

Phase shift monitoring detects an abrupt change to the period duration of the mains voltage.

The period duration of the current period is compared with the average value for the period duration over the past 4 periods. If the difference exceeds the set limit value, then triggering takes place immediately.

Limit value

Setting of the limit value takes place in 0.1° steps. The internal limit value in μs is calculated as follows:

$$t_{\text{hres}}[\mu\text{s}] = t_{\text{hres}}[0.1^\circ] * \text{Period duration} / 3600$$

When do this, the period duration for the set nominal frequency is used.

Example

Calculation of $t_{\text{hres}}[\mu\text{s}]$ at 50 Hz (period duration = 20000 μs) and limit value of 7°:

$$t_{\text{hres}}[\mu\text{s}] = 70 * 20000 \mu\text{s} / 3600 = 388.88 \mu\text{s} \text{ (rounded to } 389 \mu\text{s)}$$

If the period duration thus changes abruptly by more than +389 μs , triggering takes place.

Maximum phase difference for a single phase

Name:

ConfigOutput78

ConfigOutput78Read

Triggering occurs if the electrical angle of the voltage curve shifts by more than the set angle on at least one phase.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------|------------|
| UINT | 0 to 990 | For 0 to 99° | 0.1° |

Maximum phase difference for three phases

Name:

ConfigOutput79

ConfigOutput79Read

Triggering occurs if the electrical angle of the voltage curve shifts by more than the set angle on all 3 phases.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------|------------|
| UINT | 0 to 990 | For 0 to 99° | 0.1° |

Minimum voltage for phase shift monitoring

Name:

ConfigOutput88

ConfigOutput88Read

A minimum voltage can be set. Phase shift monitoring is only active if the voltage on all 3 phases exceeds this value. The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|---------------------------------|------------|
| UINT | 0 to 2000 | For 0 to 200% of $U_{NomMains}$ | 0.1% |

Mains frequency change**Response value for mains frequency change (df/dt)**

Name:

ConfigOutput80

ConfigOutput80Read

For df/dt monitoring, the frequency change in each period is compared to the previous period.

If this value exceeds the configured limit value in each of the periods for the specified number of periods and the sign for the frequency change is always the same, the error message "Df/dt (mains frequency change)" is indicated (register "[StatusInputPacked02](#)" on page 2912) and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-------------------|------------|
| UINT | 0 to 1000 | For 0 to 100 Hz/s | 0.1 Hz/s |

Number of periods for mains frequency change (df/dt)

Name:

ConfigOutput87

ConfigOutput87Read

This register is used to define the number of periods for monitoring the mains frequency change. For activation, the response value must be continually exceeded at least for as many periods as specified in this register. The display of the error message on output DO5 takes place max. 2 ms after internal detection.

The value of this register can be read back.

Example

The maximum tripping time at 4 periods and 50 Hz mains frequency is calculated as follows:

Max. tripping time = $4 \times 20 \text{ ms} + 2 \text{ ms} = 82 \text{ ms}$

The change in period duration caused by the frequency gradients must also be accounted for.

| Data type | Value | Information | Resolution |
|-----------|----------|-------------|------------|
| UINT | 1 to 250 | - | - |

DO5 function**DO5 function**

Name:

ConfigOutput81

ConfigOutput81Read

This digital output can be set after the defined response time has elapsed depending on the assignment of the mains' monitoring variables.

The monitoring variables can be assigned to this input either individually or with additional monitoring variables using an OR operator. This makes it possible to set the output when there are multiple monitoring variables.

The following table is an overview of the monitoring functions that can be assigned to the monitoring output.

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Error notification |
|---------|-----------------------------|-------|------------------------|
| 0 | Overvoltage (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 1 | Undervoltage (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 2 | Overfrequency | 0 | Do not assign function |
| | | 1 | Assign function |
| 3 | Underfrequency | 0 | Do not assign function |
| | | 1 | Assign function |
| 4 | Voltage asymmetry | 0 | Do not assign function |
| | | 1 | Assign function |
| 5 | Phase shift - 1-/3-phase | 0 | Do not assign function |
| | | 1 | Assign function |
| 6 | Df/dt exceeded | 0 | Do not assign function |
| | | 1 | Assign function |
| 7 | Undervoltage 2 (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |
| 8 | Overvoltage 2 (of a phase) | 0 | Do not assign function |
| | | 1 | Assign function |

| | | 1 | Assign function |
| 10 | Overfrequency 2 | 0 | Do not assign function |
| | | 1 | Assign function |
| 11 | Microgrid monitoring | 0 | Do not assign function |
| | | 1 | Assign function |
| 12 - 15 | Reserved | - | |

Information:

The minimum pulse duration when a monitoring function responds to both the fault bit via X2X as well as on the output is 500 ms.

9.26.3.19.4.7 Busbar**Busbar nominal voltage (U_{NomBus})**

Name:

ConfigOutput03

ConfigOutput03Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------------|------------|
| UINT | 70 to 65000 | For 70 to 65000 V | 1 V |

Multiplier for busbar

Name:

ConfigOutput05

ConfigOutput05Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 thus means a multiplier factor of 1 (measured value not changed).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|--------------------|------------|
| UINT | 1 to 65535 | For 0.01 to 655.35 | 0.01 |

Minimum busbar voltage (U_{Bmin})

Name:

ConfigOutput40

ConfigOutput40Read

Configurable threshold for zero voltage monitoring of the busbar based on its nominal voltage. DO3 is set if the value falls below the configured threshold.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-------------------------------|------------|
| UINT | 0 to 1000 | For 0 to 100% of U_{NomBus} | 0.1% |

9.26.3.19.4.8 Synchronization**Synchronization mode**

Name:

ConfigOutputPacked01

ConfigOutput17 to ConfigOutput19

If multiple mode bits are set at the same time, then no mode will be selected (type BOOL).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------|-------|----------------------|
| 0 | ConfigOutput17 | 0 | Sync mode ≠ Slip |
| | | 1 | Sync mode = Slip |
| 1 | ConfigOutput18 | 0 | Sync mode ≠ Check |
| | | 1 | Sync mode = Check |
| 2 | ConfigOutput19 | 0 | Sync mode ≠ Dead bus |
| | | 1 | Sync Mode = Dead bus |
| 3 - 7 | Reserved | - | |

Synchronization configuration

Name:

ConfigOutput56

ConfigOutput56Read

This register contains parameters for configuring which mains or voltages should be synchronized with each other.

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|--|-------|---|
| 0 - 1 | Synchronization configuration (synchronization mains - mains being synchronized) | 00 | X4 - X6: Synchronization mains 1 - Synchronization mains 2 The configuration X4 - X6 is only possible if "Sync mains 1 / Sync mains 2" is configured in the "ConfigOutput68" on page 2875 register. |
| | | 01 | X4 - X5: Synchronization mains 1 - Busbar |
| | | 10 | X4 - X3: Synchronization mains 1 - Generator |
| | | 11 | X5 - X3: Busbar - Generator |
| 2 - 7 | Reserved | 0 | |
| 8 | Synchronization output | 0 | Digital output 4 |
| | | 1 | Digital output 6 - Output must be configured as a synchronization output (see register "ConfigOutput24" on page 2876) |
| 9 - 15 | Reserved | 0 | |

Max. differential frequency (df_{max})

Name:

ConfigOutput11

ConfigOutput11Read

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded. This value specifies the upper frequency (positive value corresponds to positive slip → generator frequency is greater than the busbar frequency when synchronizing).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|---------|---------------------|------------|
| UINT | 2 to 49 | For 0.02 to 0.49 Hz | 0.01 Hz |

Min. differential frequency (df_{min})

Name:

ConfigOutput12

ConfigOutput12Read

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded in the negative direction. This value specifies the lower frequency (negative value corresponds to negative slip → generator frequency is less than the busbar frequency when synchronizing).

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|-------------------|------------|
| INT | -49 to 0 | For -0.49 to 0 Hz | 0.01 Hz |

Max. differential voltage (dU_{max})

Name:

ConfigOutput13

ConfigOutput13Read

A switch-on command on DO4 is only output if this configured differential voltage percentage based on the synchronization mains' nominal voltage is not exceeded.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|--------------------------------|------------|
| UINT | 1 to 300 | For 0.1 to 30% of U_{NomSyn} | 0.1% |

Max. permitted differential angle (ϕ_{Max})

Name:

ConfigOutput14

ConfigOutput14Read

A switch-on command on DO4 is only output if the configured differential angle between the two synchronization mains is not exceeded.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|----------|----------------|------------|
| UINT | 1 to 600 | For 0.1 to 60° | 0.1° |

Phase rotation of sync mains 1 ($d\alpha$)

Name:

ConfigOutput15

ConfigOutput15Read

This parameter is used for correcting any phase shifting from upstream transformer vector groups before reaching the mains being synchronized.

This parameter specifies how many degrees the synchronization mains lags behind the mains being synchronized.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|---------------|------------|
| UINT | 0 to 3600 | For 0 to 360° | 0.1° |

Pulse duration of the switch-on relay

Name:

ConfigOutput47 (DO4)

ConfigOutput95 (DO6)

ConfigOutput47Read (DO4)

ConfigOutput95Read (DO6)

The duration of the switch-on pulse can be adjusted for the following switching units.

The value of this register can be read back.

| Data type | Values | Information | Resolution |
|-----------|------------|-----------------|------------|
| UINT | 40 to 1000 | For 0.04 to 1 s | 0.001 s |

Switching response time of the power switch

Name:

ConfigOutput48 (DO4)

ConfigOutput96 (DO6)

ConfigOutput48Read (DO4)

ConfigOutput96Read (DO6)

The actuation time of the generator power switch corresponds to the lead time of the switch-on command. The switch-on command is executed before the point of synchronization according to the amount of time defined here.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-------------------|------------|
| UINT | 40 to 300 | For 0.04 to 0.3 s | 0.001 s |

Dead bus voltage ($U_{BminSync}$)

Name:

ConfigOutput58

ConfigOutput58Read

Configurable threshold for dead bus synchronization based on the nominal voltage of the busbar.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-----------|-------------------------------|------------|
| UINT | 0 to 1000 | For 0 to 100% of U_{NomBus} | 0.1% |

2-phase synchronization for commissioning tests

Name:

ConfigOutput93

ConfigOutput93Read

2-phase synchronization for commissioning tests.

The value of this register can be read back.

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|-----------------|-------|---|
| 0 | Synchronization | 0 | 3-phase synchronization (normal operation) |
| | | 1 | 2-phase synchronization with L1 and L2 (commissioning tests with 2-phase simulation design) |
| 1 - 7 | Reserved | 0 | |

Information:

It is only possible to set 2-phase synchronization for commissioning tests with a 2-phase simulation design.

If only 2 phases are connected, then the respective mains must be configured with neutral conductors since a network with a "virtual neutral point" is not possible with 2 phases (see register "[ConfigOutput68](#)" on page 2875).

9.26.3.19.4.9 Maximum value buffer and power meter**Pulse value of energy meter output**

Name:

ConfigOutput46

ConfigOutput46Read

Output DO2 outputs pulses that occur at a frequency proportional to the measured energy. The frequency of the pulses can be specified. The length of the pulse is 400 ms. The frequency at which the pulses occur should be set so that the duration between two pulses does not exceed 400 ms at the highest possible power. The pulse output's internal meter starts at 0 kWh after a restart. This register has no effect on the "ConfigOutput54" on page 2909 and "ConfigOutput55" on page 2909 registers.

When set to 0, meter output is disabled.

Depending on how the "Power measurement mode" parameter is set in the "ConfigOutput21" on page 2878 register, either the total active power or the active power of the fundamental wave is added together. Changing the parameter "Power measurement mode" during runtime does not cause the internal energy meter to restart.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|------------|--------------------------|-------------|
| UINT | 0 to 65535 | For 0 to 65535 kWh/pulse | 1 kWh/pulse |

Count value for active energy meter and reactive energy meter

Name:

ConfigOutput94

ConfigOutput94Read

This parameter is used to configure the resolution of active and reactive energy counters.

The value of this register can be read back.

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 1 kWh |

Maximum value buffer and meter buffer

These registers are used for nonvolatile storage of the maximum value and meter level values. After restarting, the stored maximum values and meter states are loaded back into their registers and the module's internal work meter is reset. It is possible to reset or write to the stored maximum values and meter states using an acyclic register.

The maximum values are recorded by the effective measured values before reaching the configurable filter. The maximum values can be read or written to as acyclic registers.

Maximum phase current

Name:

Reading: ConfigOutput49 (generator I1)

Reading: ConfigOutput50 (generator I2)

Reading: ConfigOutput51 (generator I3)

Writing: ConfigOutput60 (generator I1)

Writing: ConfigOutput61 (generator I2)

Writing: ConfigOutput62 (generator I3)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Maximum total active power (supplied power)

Name:

Reading: ConfigOutput52

Writing: ConfigOutput63

Depending on the status of the "Power measurement mode" parameter in the "ConfigOutput21" on page 2878 register, either the total power or the fundamental power is added together or compared.

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 kW |

Maximum neutral conductor current

Name:

Reading: ConfigOutput53

Writing: ConfigOutput64

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Active energy counter

Name:

Reading: ConfigOutput54 (delivered (producing))

Reading: ConfigOutput71 (drawn (consuming))

Writing: ConfigOutput66 (delivered (producing))

Writing: ConfigOutput69 (drawn (consuming))

Depending on the status of the "Power measurement mode" parameter in the "ConfigOutput21" on page 2878 register, either the total power or the fundamental power is added together or compared.

The resolution can be configured (see register "ConfigOutput94" on page 2908).

| Data type | Value | Information | Resolution |
|-----------|------------------------------------|-------------|------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | - | Default: 100 kWh |

Reactive energy counter

Name:

Reading: ConfigOutput55 (reactive energy meter delivered (producing))

Reading: ConfigOutput72 (reactive energy meter drawn (consuming))

Writing: ConfigOutput67 (reactive energy meter delivered (producing))

Writing: ConfigOutput70 (reactive energy meter drawn (consuming))

Depending on the status of the "Power measurement mode" parameter in the "ConfigOutput21" on page 2878 register, either the total power or the fundamental power is added together or compared.

The resolution can be configured (see register "ConfigOutput94" on page 2908).

| Data type | Value | Information | Resolution |
|-----------|------------------------------------|-------------|--------------------|
| DINT | -2,147,483,648 to 2,147,483,647 | - | Default: 100 kvarh |

9.26.3.19.5 Communication registers

9.26.3.19.5.1 General registers

DigitalOutputPacked01

Name:

DigitalOutputPacked01

DigitalOutput05

DigitalOutput06

ResetGeneratorErrors

ResetMainsErrors

InvertDO5

DigitalOutput01

The module's default configuration is that the generator and mains error bits are reset by the module. If this should be done by the user, then the module needs to be configured accordingly using the following registers.

- Generator error: "[ConfigOutput21](#)" on page 2878
- Network error: "[ConfigOutput22](#)" on page 2891

(data point applied as BOOL)

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-------|----------------------|-------|--|
| 0 | DigitalOutput05 | 0 | Reset output 5 |
| | | 1 | Set output 5 |
| 1 | DigitalOutput06 | 0 | Reset output 6 |
| | | 1 | Set output 6 |
| 2 | ResetGeneratorErrors | 0 | Does not reset generator error bits |
| | | 1 | Resets generator error bits |
| 3 | ResetMainsErrors | 0 | Do not reset mains error bits |
| | | 1 | Reset mains error bits |
| 4 | InvertDO5 | 0 | Do not invert Output 5 |
| | | 1 | Invert output 5 of the mains monitoring function |
| 5 | DigitalOutput01 | 0 | Reset output 1 |
| | | 1 | Set output 1 |
| 6 - 7 | Reserved | 0 | |

| 12 | StatusInput32 | 0 | No generator feedback |
| | | 1 | Generator feedback |
| 13 - 14 | Reserved | - | |
| 15 | StatusInput18 | 0 | Undervoltage 2 (of a phase) OK |
| | | 1 | Undervoltage 2 (of a phase) occurring |

StatusInput11

The error message "Not ready" is triggered if the X20 I/O supply drops below 18 VDC.

StatusInputPacked02

Name:

StatusInputPacked02

StatusInput24 to StatusInput30

StatusInput33

This register is the error register for the mains (error bits are of type BOOL).

| Data type | Values |
|-----------|------------------------|
| USINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|-----|---------------|-------|---------------------------------------|
| 0 | StatusInput24 | 0 | Overvoltage (one phase), OK |
| | | 1 | Overvoltage (one phase), present |
| 1 | StatusInput25 | 0 | Undervoltage (one phase), OK |
| | | 1 | Undervoltage (one phase), present |
| 2 | StatusInput26 | 0 | Over-frequency, OK |
| | | 1 | Over-frequency, present |
| 3 | StatusInput27 | 0 | Under-frequency, OK |
| | | 1 | Under-frequency, present |
| 4 | StatusInput28 | 0 | Voltage asymmetry, OK |
| | | 1 | Voltage asymmetry, present |
| 5 | StatusInput29 | 0 | Phase shift monitoring OK |
| | | 1 | Phase shift error (1/3 of a phase) |
| 6 | StatusInput30 | 0 | Df/dt OK |
| | | 1 | Df/dt error |
| 7 | StatusInput33 | 0 | Undervoltage 2 (of a phase) OK |
| | | 1 | Undervoltage 2 (of a phase) occurring |

StatusInput33

The data point is only valid if 2-point mode is configured (see register "[ConfigOutput22](#)" on page 2891). This bit only appears in the I/O mapping in Automation Studio if the corresponding status information is enabled in the I/O configuration ("Mains configuration / Additional status information" menu option).

StatusInputPacked03

Name:

StatusInputPacked03

StatusInput12 to StatusInput15

StatusInput19 to StatusInput23

This register is the error register for general error messages (error bits are of type BOOL).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------|-------|--|
| 0 | StatusInput12 | 0 | All phases of the generator mains OK |
| | | 1 | Failure of at least one phase of the generator mains |
| 1 | StatusInput13 | 0 | All phases of the busbar OK |
| | | 1 | Failure of at least one phase of the busbar |
| 2 | StatusInput14 | 0 | All phases of Sync Mains 1 OK |
| | | 1 | Failure of at least one phase of Sync Mains 1 |
| 3 | StatusInput15 | 0 | All phases of Sync Mains 2 OK |
| | | 1 | Failure of at least one phase of Sync Mains 2 |
| 4 | StatusInput19 | 0 | Phase sequence of generator voltage OK |
| | | 1 | Phase sequence of generator voltage incorrect |
| 5 | StatusInput20 | 0 | Phase sequence of generator current OK |
| | | 1 | Phase sequence of generator current incorrect |
| 6 | StatusInput21 | 0 | Phase sequence of busbar OK |
| | | 1 | Phase sequence of busbar incorrect |
| 7 | StatusInput22 | 0 | Phase sequence of Sync Mains 1 OK |
| | | 1 | Phase sequence of Sync Mains 1 incorrect |
| 8 | StatusInput23 | 0 | Phase sequence of Sync Mains 2 OK |
| | | 1 | Phase sequence of Sync Mains 2 incorrect |
| 9 - 15 | Reserved | - | |

StatusInput12 to StatusInput15: Phase failure is detected if at least one of the phases of the respective terminal fails.

StatusInput19 to StatusInput23 are status bits for detecting a change of rotation.

StatusInputPacked04

Name:

StatusInputPacked04

StatusInput34 to StatusInput37

This register is the error register for the mains (error bits are of type BOOL). These bits only appear in the I/O mapping in Automation Studio if the corresponding status information is enabled in the I/O configuration ("Mains configuration / Additional status information" menu option).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------|-------|--------------------------------------|
| 0 | StatusInput34 | 0 | Overvoltage 2 (of a phase) OK |
| | | 1 | Overvoltage 2 (of a phase) occurring |
| 1 | StatusInput35 | 0 | Underfrequency 2 OK |
| | | 1 | Underfrequency 2 occurring |
| 2 | StatusInput36 | 0 | Overfrequency 2 OK |
| | | 1 | Overfrequency 2 occurring |
| 3 | StatusInput37 | 0 | Microgrid monitoring OK |
| | | 1 | Microgrid monitoring tripped |
| 4 - 15 | Reserved | - | |

StatusInputPacked05

Name:

StatusInputPacked05

StatusInput38 to StatusInput40

This register is the error register for the generator mains (error bits are of type BOOL). These bits only appear in the I/O mapping in Automation Studio if the corresponding status information is enabled in the I/O configuration ("Generator mains / Additional status information" menu option).

| Data type | Values |
|-----------|------------------------|
| UINT | See the bit structure. |

Bit structure:

| Bit | Description | Value | Information |
|--------|---------------|-------|--------------------------------------|
| 0 | StatusInput38 | 0 | Overvoltage 2 (of a phase) OK |
| | | 1 | Overvoltage 2 (of a phase) occurring |
| 1 | StatusInput39 | 0 | Underfrequency 2 OK |
| | | 1 | Underfrequency 2 occurring |
| 2 | StatusInput40 | 0 | Overfrequency 2 OK |
| | | 1 | Overfrequency 2 occurring |
| 3 | StatusInput41 | 0 | Q-U protection OK |
| | | 1 | Q-U protection active |
| 4 - 15 | Reserved | - | |

9.26.3.19.5.2 Generator mains measured values**Phase currents of the generator**

Name:

AnalogInput01 (I1)

AnalogInput02 (I2)

AnalogInput03 (I3)

Phase currents of the generator

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Neutral conductor current of generator I_n

Name:

AnalogInput05

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Current average of generator I1, I2, I3

Name:

AnalogInput04

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

Dynamic current average of generator (I_{m_dyn})

Name:

AnalogInput06

Describes the change to the current average.

The dynamic average is the amount of change (I_{m_diff}) of the current average (sampling time: 10 ms).

This value decays in an e-function.

$$I_{m_diff} > I_{m_dyn} \rightarrow I_{m_dyn} = I_{m_diff}$$

$$I_{m_diff} \leq I_{m_dyn} \rightarrow I_{m_dyn} = I_{m_dyn} * 0.98$$

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 1 A |

Line-to-line voltages of the generator

Name:

AnalogInput07 (UG12)

AnalogInput08 (UG23)

AnalogInput09 (UG31)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Phase voltages of the generator

Name:

AnalogInput10 (UG 1)

AnalogInput11 (UG 2)

AnalogInput12 (UG 3)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Voltage average of the generator

Name:

AnalogInput22

Voltage average of the generator UG12, UG23, UG31 (U~3 average)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Filtered generator power values:

Name:

AnalogInput19

AnalogInput20

AnalogInput21

Filtered generator power values:

- Total output (sum of all harmonic frequencies)
- Fundamental frequency power (_H1)

Configuration is explained in the "[ConfigOutput21](#)" on [page 2878](#) register.

| Data type | Value | Information | Resolution |
|-----------|-----------------|-----------------------------|------------|
| INT | -32768 to 32767 | Total active power P/P_H1 | 1 kW |
| | -32768 to 32767 | Total reactive power Q/Q_H1 | 1 kvar |
| | -32768 to 32767 | Total apparent power S/S_H1 | 1 kVA |

Power factor of generator/cos ϕ

Name:

AnalogInput23

The factor is described in "[Power factor of the generator](#)" on [page 2865](#) and register "[ConfigOutput21](#)" on [page 2878](#).

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 0.001 |

Frequency of the generator mains

Name:

AnalogInput24

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

Timestamp for generator voltages and currents

These timestamps mark the last positive zero crossing of the generator voltages (L1-N, L2-N, L3-N) and generator currents (I1, I2, I3). They can be used to calculate all the necessary phase ratios.

Calculation of the phase ratios and error handling for the calculations are to be implemented by the user (e.g. period duration monitoring or verification that the voltages are high enough, etc.).

These timestamps only appear in the I/O mapping in Automation Studio if they are enabled in the I/O configuration ("Enable timestamps for generator voltage and current" menu option).

Timestamp of pos. zero crossing of phase voltage

Name:

AnalogInput38 (UG1)

AnalogInput39 (UG2)

AnalogInput40 (UG3)

Time stamp of pos. zero crossing of phase voltage of the respective generator

| Data type | Value | Information | Resolution |
|-----------|------------------------------------|-------------|------------|
| DINT | -2,147,483,648 to 2,147,483,647 | - | 1/4096 µs |

Timestamp of pos. zero crossing of phase current

Name:

AnalogInput41 (I1)

AnalogInput42 (I2)

AnalogInput43 (I3)

Time stamp of pos. zero crossing of phase current of the respective generator

| Data type | Value | Information | Resolution |
|-----------|------------------------------------|-------------|------------|
| DINT | -2,147,483,648 to 2,147,483,647 | - | 1/4096 µs |

Instantaneous values of the phase currents generator

Name:

AnalogInput48 (I1)

AnalogInput49 (I2)

AnalogInput50 (I3)

The instantaneous measured values of the respective phase currents are applied here. To calculate the actual physical quantities, the transferred values must be multiplied by the multiplier for the current transformer ("[ConfigOutput09Read](#)" on page 2877). To avoid aliasing through transfer in the X2X cycle, the values are pre-filtered on the module.

| Data type | Values | Information | Resolution |
|-----------|-----------------|---|------------|
| UINT | -32768 to 32767 | Corresponds to the direct measured values of the phase currents | - |

Instantaneous values of the phase voltages generator

Name:

AnalogInput45 (UG1)

AnalogInput46 (UG2)

AnalogInput47 (UG3)

The instantaneous measured values of the respective phase voltages are applied here. To calculate the actual physical quantities, the transferred values must be multiplied by the multiplier for the generator mains ("[ConfigOutput06Read](#)" on page 2877). To avoid aliasing through transfer in the X2X cycle, the values are pre-filtered on the module.

| Data type | Values | Information | Resolution |
|-----------|-----------------|---|------------|
| UINT | -32768 to 32767 | Corresponds to the direct measured values of the phase voltages | - |

Counter for real-time values

Name:
LifeCnt

The counter is incremented with each X2X cycle (new instantaneous values are available 1x per X2X cycle). This makes it possible in the application to detect whether values were skipped or the same value was read twice.

In principle, tasks in which the instantaneous values are processed should have a cycle time equal to the X2X cycle time. If the task cycle time is a multiple of the X2X cycle time, this must be taken into account when configuring register "ConfigOutput125" on page 2879.

| Data type | Values | Information | Resolution |
|-----------|-------------|---|------------|
| SINT | -128 to 127 | Counter incremented if new instantaneous values available | - |

9.26.3.19.5.3 Busbar measured values**Line-to-line voltages of the busbar**

Name:
AnalogInput13 (UB12)
AnalogInput14 (UB23)
AnalogInput15 (UB31)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Phase voltages of the busbar

Name:
AnalogInput16 (UB1)
AnalogInput17 (UB2)
AnalogInput18 (UB3)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Frequency of busbar

Name:
AnalogInput35

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

9.26.3.19.5.4 Measured value of synchronization mains

(for mains configuration "Sync mains 1 / Sync mains 2")

Line-to-line voltages

Name:

AnalogInput25 (sync mains 1 US1)

AnalogInput26 (sync mains 2 US2)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Frequencies

Name:

AnalogInput27 (sync mains 1)

AnalogInput28 (sync mains 2)

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

9.26.3.19.5.5 Measured value of mains

(for "3-phase mains" configuration)

Line-to-line voltages of mains

Name:

AnalogInput25 (UN12)

AnalogInput31 (UN23)

AnalogInput32 (UN31)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Phase voltages of the generator

Name:

AnalogInput33 (UN1)

AnalogInput34 (UN2)

AnalogInput26 (UN3)

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

Frequency of power mains

Name:

AnalogInput27

| Data type | Value | Information | Resolution |
|-----------|-------------|-------------|------------|
| UINT | 0 to 65,535 | - | 0.01 Hz |

9.26.3.19.5.6 Generator monitoring**Read unbalanced load meter**

Name:

AnalogInput36

This register can be used to track the current state of the unbalanced load meter (see "[Dependent delayed unbalanced load monitoring](#)" on page 2882). The unbalanced load meter can be reset with an acyclic trigger bit (see register "[ConfigOutput23](#)" on page 2877).

| Data type | Value | Information | Resolution |
|-----------|------------|---------------|------------|
| UINT | 0 to 65535 | For 0 to 100% | |

Reads the unbalanced load current (I₂)

Name:

AnalogInput37

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 A |

9.26.3.19.5.7 Synchronization**Differential angle between synchronization mains**

Name:

AnalogInput29

Angular difference between the mains being synchronized

Specifies how many degrees the sync mains are ahead of the mains being synchronized.

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 0.1° |

Differential voltage between synchronization mains

Name:

AnalogInput30

Voltage difference between the mains being synchronized

| Data type | Value | Information | Resolution |
|-----------|-----------------|-------------|------------|
| INT | -32768 to 32767 | - | 1 V |

9.26.3.19.6 Minimum cycle time

The minimum cycle time specifies the time up to which the bus cycle can be reduced without communication errors occurring. It is important to note that very fast cycles reduce the idle time available for handling monitoring, diagnostics and acyclic commands.

| Minimum cycle time |
|--------------------|
| 250 μ s |

9.26.3.19.7 Minimum I/O update time

The minimum I/O update time for the analog inputs depends on the respective period duration of the measurement signal frequency.

| Minimum I/O update time |
|-------------------------|
| At 50 Hz 10 ms |

9.26.4 X20(c)CM0985-1

Data sheet version: 1.42

9.26.4.1 General information

The module has a compact size and combines a power measurement module that has special features with a synchronization unit that is able to meet all demands.

The measurement unit's 3 current inputs are suitable for both X: 1 A and X: 5 A current transformers. Overcurrent resistance and the high resolution of the measurement unit round off its features. For the voltage inputs, the value range can be configured between 480 VAC and 120 VAC.

The area of use includes 4-wire AC networks with a phase voltage up to 480 VAC and 3-wire systems, whereas L2 can be grounded (V-connection). The module can also handle Aron measuring circuits.

The resulting measured values include the pure phase current; line-to-line voltage or phase voltage; the effective, reactive and apparent power parts; the mains frequency; the power factor and much more. In addition, peak values and energy meters are stored on the module in nonvolatile memory. Depending on the configuration, it is also possible to use a digital output as a pulse encoder for an external energy meter.

The synchronization unit doesn't just take the phasing and phase voltage into consideration; integrated intelligence also monitors the rate of change and other parameters, allowing them to influence when the synchronization output is switched. It is also possible to monitor a generator using a large number of additional conditions. A total of 4 voltage inputs provide substantial overall flexibility.

Monitoring functions expand the features of the module. Rating-dependent overcurrent monitoring is included, which utilizes the thermal capacity of the motor/generator to allow short overloads while still providing full protection. The dependent, delayed imbalanced load monitoring used to protect three-phase generator and three-phase networks from imbalanced load can be adapted to the characteristics of different generator types using parameters while taking their special thermal time constants into account.

- Energy measurement for 120 to 480 VAC
- Simultaneous measurement of 2 AC mains networks plus 2 additional voltages
- For multifunctional measurement tasks
- Intelligent mains synchronization unit

Information:

Please refer to section "[Safety guidelines](#)" on page 2925 before operating the module.

9.26.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.

The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, method 4, exposure 21 days

9.26.4.3 Order data
